

Chapter P: Preparing for Calculus

P.1: Functions and Their Graphs

Concepts and Vocabulary

1. If f is a function defined by $y = f(x)$, then x is called the **independent** variable and y is the **dependent** variable.
2. **True**. The independent variable is sometimes referred to as the argument of the function.
3. **False**. If no domain is specified for a function f , then the domain of f is taken to be the largest set of real numbers for which the value $f(x)$ is defined and is a real number.
4. **False**. The domain of the function $f(x) = \frac{3(x^2 - 1)}{x - 1}$ is the set $\{x|x \neq 1\}$.
5. **False**. A function can have at most one y -intercept; otherwise, there would be more than one y -value corresponding to $x = 0$.
6. A set of points in the xy -plane is the graph of a function if and only if every **vertical** line intersects the graph in at most one point.
7. If the point $(5, -3)$ is on the graph of f , then $f(\boxed{5}) = \boxed{-3}$.
8. Let $f(x) = ax^2 + 4$. For the point $(-1, 2)$ to be on the graph of f , we must have $f(-1) = 2$. But $f(-1) = a(-1)^2 + 4 = a + 4$, so we must have $a + 4 = 2$, or $\boxed{a = -2}$.
9. A function f is **(a) increasing** on an interval I if, for any choice of x_1 and x_2 in I , with $x_1 < x_2$, then $f(x_1) < f(x_2)$.
10. A function is **(a) even** if for every number x in its domain, the number $-x$ is also in the domain and $f(-x) = f(x)$. A function f is **(b) odd** if for every number x in its domain, the number $-x$ is also in the domain and $f(-x) = -f(x)$.
11. **False**. Even functions have graphs that are symmetric with respect to the y -axis. Odd functions have graphs that are symmetric with respect to the origin.
12. The average rate of change of $f(x) = 2x^3 - 3$ from 0 to 2 is

$$\frac{f(2) - f(0)}{2 - 0} = \frac{2(2)^3 - 3 - (2(0)^3 - 3)}{2} = \frac{13 - (-3)}{2} = \frac{16}{2} = \boxed{8}.$$

Practice Problems

13. Let $f(x) = 3x^2 + 2x - 4$. Then
 - (a) $f(0) = 3(0)^2 + 2(0) - 4 = \boxed{-4}$.
 - (b) $f(-x) = 3(-x)^2 + 2(-x) - 4 = \boxed{3x^2 - 2x - 4}$.
 - (c) $-f(x) = -(3x^2 + 2x - 4) = \boxed{-3x^2 - 2x + 4}$.
 - (d) $f(x + 1) = 3(x + 1)^2 + 2(x + 1) - 4 = 3(x^2 + 2x + 1) + 2x + 2 - 4 = \boxed{3x^2 + 8x + 1}$.

$$(e) f(x+h) = 3(x+h)^2 + 2(x+h) - 4 = 3(x^2 + 2xh + h^2) + 2x + 2h - 4 = \boxed{3x^2 + 6xh + 3h^2 + 2x + 2h - 4}.$$

14. Let $f(x) = \frac{x}{x^2 + 1}$. Then

$$(a) f(0) = \frac{0}{0^2 + 1} = \boxed{0}.$$

$$(b) f(-x) = \frac{-x}{(-x)^2 + 1} = \boxed{-\frac{x}{x^2 + 1}}.$$

$$(c) -f(x) = \boxed{-\frac{x}{x^2 + 1}}.$$

$$(d) f(x+1) = \frac{x+1}{(x+1)^2 + 1} = \boxed{\frac{x+1}{x^2 + 2x + 2}}.$$

$$(e) f(x+h) = \frac{x+h}{(x+h)^2 + 1} = \boxed{\frac{x+h}{x^2 + 2xh + h^2 + 1}}.$$

15. Let $f(x) = |x| + 4$. Then

$$(a) f(0) = |0| + 4 = \boxed{4}.$$

$$(b) f(-x) = |-x| + 4 = \boxed{|x| + 4}.$$

$$(c) -f(x) = -(|x| + 4) = \boxed{-|x| - 4}.$$

$$(d) f(x+1) = \boxed{|x+1| + 4}.$$

$$(e) f(x+h) = \boxed{|x+h| + 4}.$$

16. Let $f(x) = \sqrt{3-x}$. Then

$$(a) f(0) = \sqrt{3-0} = \boxed{\sqrt{3}}.$$

$$(b) f(-x) = \sqrt{3-(-x)} = \boxed{\sqrt{3+x}}.$$

$$(c) -f(x) = \boxed{-\sqrt{3-x}}.$$

$$(d) f(x+1) = \sqrt{3-(x+1)} = \boxed{\sqrt{2-x}}.$$

$$(e) f(x+h) = \sqrt{3-(x+h)} = \boxed{\sqrt{3-x-h}}.$$

17. Because $f(x) = x^3 - 1$ is defined for any real number x , the domain of f is the set of $\boxed{\text{all real numbers}}$, or in interval notation $\boxed{(-\infty, \infty)}$.

18. Because $x^2 + 1$ is never equal to zero for any real number x , $f(x) = \frac{x}{x^2 + 1}$ is defined for any real number x . The domain of f is therefore the set of $\boxed{\text{all real numbers}}$, or in interval notation $\boxed{(-\infty, \infty)}$.

19. Because the square root of a negative number is not a real number, the value of $t^2 - 9$ must be nonnegative. The solution of the inequality $t^2 - 9 \geq 0$ is $\{t|t \leq -3\} \cup \{t|t \geq 3\}$, so the domain of v is the set of real numbers $\boxed{\{t|t \leq -3\} \cup \{t|t \geq 3\}}$, or in interval notation $\boxed{(-\infty, -3] \cup [3, \infty)}$.

20. Because the expression $x - 1$ appears under the square root and in the denominator, the value of $x - 1$ must be positive; that is, $x - 1 > 0$. The solution of this inequality is $\{x|x > 1\}$, so the domain of g is the set of real numbers $\boxed{\{x|x > 1\}}$, or in interval notation $\boxed{(1, \infty)}$.

21. Because division by zero is not defined, $x^3 - 4x = x(x^2 - 4) = x(x - 2)(x + 2)$ cannot be zero; that is, $x \neq 0$, $x \neq 2$, and $x \neq -2$. Thus, the domain of h is the set of real numbers $\boxed{\{x|x \neq -2, x \neq 0, x \neq 2\}}$.

22. Because the square root of a negative number is not a real number, the value of $t + 1$ must be nonnegative. The solution of the inequality $t + 1 \geq 0$ is $\{t|t \geq -1\}$. Moreover, because division by zero is not defined, $t - 5$ cannot be 0; that is, t cannot be equal to 5. The intersection of the sets $\{t|t \geq -1\}$ and $\{t|t \neq 5\}$ is the set $\{t|-1 \leq t < 5\} \cup \{t|t > 5\}$. The domain of s is therefore the set of real numbers $\boxed{\{t|-1 \leq t < 5\} \cup \{t|t > 5\}}$, or in interval notation $\boxed{[-1, 5) \cup (5, \infty)}$.

23. Let $f(x) = -3x + 1$. Then

$$\frac{f(x+h) - f(x)}{h} = \frac{-3(x+h) + 1 - (-3x+1)}{h} = \frac{-3x - 3h + 1 + 3x - 1}{h} = \frac{-3h}{h} = \boxed{-3}.$$

24. Let $f(x) = \frac{1}{x+3}$. Then

$$\begin{aligned} \frac{f(x+h) - f(x)}{h} &= \frac{\frac{1}{x+h+3} - \frac{1}{x+3}}{h} \cdot \frac{(x+h+3)(x+3)}{(x+h+3)(x+3)} \\ &= \frac{x+3 - (x+h+3)}{h(x+h+3)(x+3)} = \frac{-h}{h(x+h+3)(x+3)} = \boxed{-\frac{1}{(x+h+3)(x+3)}}. \end{aligned}$$

25. Let $f(x) = \sqrt{x+7}$. Then

$$\begin{aligned} \frac{f(x+h) - f(x)}{h} &= \frac{\sqrt{x+h+7} - \sqrt{x+7}}{h} \cdot \frac{\sqrt{x+h+7} + \sqrt{x+7}}{\sqrt{x+h+7} + \sqrt{x+7}} \\ &= \frac{x+h+7 - (x+7)}{h(\sqrt{x+h+7} + \sqrt{x+7})} = \frac{h}{h(\sqrt{x+h+7} + \sqrt{x+7})} = \boxed{\frac{1}{\sqrt{x+h+7} + \sqrt{x+7}}}. \end{aligned}$$

26. Let $f(x) = \frac{2}{\sqrt{x+7}}$. Then

$$\begin{aligned} \frac{f(x+h) - f(x)}{h} &= \frac{\frac{2}{\sqrt{x+h+7}} - \frac{2}{\sqrt{x+7}}}{h} \cdot \frac{\sqrt{x+h+7}\sqrt{x+7}}{\sqrt{x+h+7}\sqrt{x+7}} \\ &= \frac{2\sqrt{x+7} - 2\sqrt{x+h+7}}{h\sqrt{x+h+7}\sqrt{x+7}} \cdot \frac{\sqrt{x+7} + \sqrt{x+h+7}}{\sqrt{x+7} + \sqrt{x+h+7}} \\ &= \frac{2(x+7) - 2(x+h+7)}{h\sqrt{x+h+7}\sqrt{x+7}(\sqrt{x+7} + \sqrt{x+h+7})} \\ &= \frac{-2h}{h\sqrt{x+h+7}\sqrt{x+7}(\sqrt{x+7} + \sqrt{x+h+7})} \\ &= \boxed{-\frac{2}{\sqrt{x+h+7}\sqrt{x+7}(\sqrt{x+7} + \sqrt{x+h+7})}}. \end{aligned}$$

27. Let $f(x) = x^2 + 2x$. Then

$$\begin{aligned} \frac{f(x+h) - f(x)}{h} &= \frac{(x+h)^2 + 2(x+h) - (x^2 + 2x)}{h} = \frac{x^2 + 2xh + h^2 + 2x + 2h - x^2 - 2x}{h} \\ &= \frac{2xh + h^2 + 2h}{h} = \frac{h(2x + h + 2)}{h} = \boxed{2x + h + 2}. \end{aligned}$$

28. Let $f(x) = (2x + 3)^2$. Then

$$\begin{aligned}\frac{f(x+h) - f(x)}{h} &= \frac{(2(x+h) + 3)^2 - (2x + 3)^2}{h} = \frac{4(x+h)^2 + 12(x+h) + 9 - (4x^2 + 12x + 9)}{h} \\ &= \frac{4x^2 + 8xh + 4h^2 + 12x + 12h + 9 - 4x^2 - 12x - 9}{h} \\ &= \frac{8xh + 4h^2 + 12h}{h} = \frac{h(8x + 4h + 12)}{h} = \boxed{8x + 4h + 12}.\end{aligned}$$

29. This graph fails the vertical line test (for example, the vertical line $x = 2$ intersects the graph in two points), so it **does not represent a function**.

30. This graph passes the vertical line test, and so it **does represent a function**.

(a) From the graph, the domain of the function is the set of **all real numbers** or the interval $(-\infty, \infty)$, and the range of the function is the set of **all positive real numbers** or the interval $(0, \infty)$.

(b) The graph has no x -intercepts, and the y -intercept is 1. Thus, the only intercept is $(0, 1)$.

(c) The graph is not symmetric with respect to the x -axis, the y -axis, or the origin.

31. This graph passes the vertical line test, and so it **does represent a function**.

(a) From the graph, the domain of the function is the set $\{x \mid -\pi \leq x \leq \pi\}$ or the closed interval $[-\pi, \pi]$, and the range of the function is the set $\{y \mid -1 \leq y \leq 1\}$ or the closed interval $[-1, 1]$.

(b) The graph has x -intercepts of $\pm \frac{\pi}{2}$ and a y -intercept of 1, so the intercepts are $(\pm \frac{\pi}{2}, 0)$ and $(0, 1)$.

(c) The graph is symmetric with respect to the y -axis but not symmetric with respect to the x -axis or the origin.

32. This graph fails the vertical line test (for example, the vertical line $x = 2$ intersects the graph in two points), so it **does not represent a function**.

33. (a) $\boxed{f(-1) = -1 + 3 = 2; f(0) = 0 + 3 = 3; f(1) = 5; f(8) = -8 + 2 = -6}$

(b) The graph of f consists of three pieces corresponding to each equation in the definition. On the interval $[-2, 1)$, the graph is the line $y = x + 3$, and on the interval $(1, \infty)$, the graph is the line $y = -x + 2$. The graph also contains the point $(1, 5)$.

- (c) The individual components of f have domains of $\{x | -2 \leq x < 1\}$, $\{x | x = 1\}$, and $\{x | x > 1\}$. The domain of f is the union of these three sets; that is, $\{x | x \geq -2\}$ in set notation or $[-2, \infty)$ in interval notation. Moreover, the individual components of f have ranges of $\{y | 1 \leq y < 4\}$, $\{y | y = 5\}$, and $\{y | y < 1\}$. The range of f is the union of these three sets; that is, $\{y | y = 5 \text{ or } y < 4\}$ in set notation or $(-\infty, 4) \cup \{5\}$ in interval notation. The x -intercept is 2, and the y -intercept is 3, so the intercepts are $(2, 0)$ and $(0, 3)$.

34. (a) $f(-1) = 2(-1) + 5 = 3; f(0) = -3; f(1) = -5(1) = -5; f(8) = -5(8) = -40$

- (b) The graph of f consists of three pieces corresponding to each equation in the definition. On the interval $[-3, 0)$, the graph is the line $y = 2x + 5$, and on the interval $(0, \infty)$, the graph is the line $y = -5x$. The graph also contains the point $(0, -3)$.

- (c) The individual components of f have domains of $\{x | -3 \leq x < 0\}$, $\{x | x = 0\}$, and $\{x | x > 0\}$. The domain of f is the union of these three sets; that is, $\{x | x \geq -3\}$ in set notation or $[-3, \infty)$ in interval notation. Moreover, the individual components of f have ranges of $\{y | -1 \leq y < 5\}$, $\{y | y = -3\}$, and $\{y | y < 0\}$. The range of f is the union of these three sets; that is, $\{y | y < 5\}$ in set notation or $(-\infty, 5)$ in interval notation. The x -intercept is $-\frac{5}{2}$, and the y -intercept is -3 , so the intercepts are $(-\frac{5}{2}, 0)$ and $(0, -3)$.

35. (a) $f(-1) = 1 + (-1) = 0; f(0) = 0^2 = 0; f(1) = 1^2 = 1; f(8) = 8^2 = 64$

- (b) The graph of f consists of two pieces corresponding to each equation in the definition. On the interval $(-\infty, 0)$, the graph is the line $y = 1 + x$, and on the interval $[0, \infty)$, the graph is the parabola $y = x^2$.

- (c) The individual components of f have domains of $\{x|x < 0\}$ and $\{x|x \geq 0\}$. The domain of f is the union of these two sets; that is, all real numbers or the interval $(-\infty, \infty)$. Moreover, the individual components of f have ranges of $\{y|y < 1\}$ and $\{y|y \geq 0\}$. The range of f is the union of these two sets; that is, all real numbers or the interval $(-\infty, \infty)$. The x -intercepts are -1 and 0 , and the y -intercept is 0 , so the intercepts are $(-1, 0)$ and $(0, 0)$.

36. (a) $f(-1) = \frac{1}{-1} = -1$; $f(0) = \sqrt[3]{0} = 0$; $f(1) = \sqrt[3]{1} = 1$; $f(8) = \sqrt[3]{8} = 2$

- (b) The graph of f consists of two pieces corresponding to each equation in the definition. On the interval $(-\infty, 0)$, the graph is $y = \frac{1}{x}$, and on the interval $[0, \infty)$, the graph is $y = \sqrt[3]{x}$.

- (c) The individual components of f have domains of $\{x|x < 0\}$ and $\{x|x \geq 0\}$. The domain of f is the union of these two sets; that is, all real numbers or the interval $(-\infty, \infty)$. Moreover, the individual components of f have ranges of $\{y|y < 0\}$ and $\{y|y \geq 0\}$. The range of f is the union of these two sets; that is, all real numbers or the interval $(-\infty, \infty)$. The x -intercept is 0 , and the y -intercept is 0 , so the only intercept is $(0, 0)$.

37. Because the graph of f includes the point $(0, 3)$, $f(0) = 3$; because the graph also includes the point $(-6, -3)$, $f(-6) = -3$.

38. Because the graph of f lies above the x -axis at $x = 3$, $f(3)$ is positive.

39. Because the graph of f lies below the x -axis at $x = -4$, $f(-4)$ is negative.
40. Because the graph of f includes the points $(-3, 0)$, $(6, 0)$, and $(10, 0)$, $f(x) = 0$ for $x = -3$, $x = 6$, and $x = 10$.
41. Because the graph of f lies above the x -axis for $-3 < x < 6$ and for $10 < x \leq 11$, $f(x) > 0$ for $-3 < x < 6$ and for $10 < x \leq 11$. In interval notation, this can be written as $(-3, 6) \cup (10, 11]$.
42. The points on the graph of f have x -coordinates between -6 and 11 inclusive. The domain of f is therefore the set of real numbers $\{x | -6 \leq x \leq 11\}$ or the closed interval $[-6, 11]$.
43. The points on the graph of f have y -coordinates between -3 and 3 inclusive. The range of f is therefore the set of real numbers $\{y | -3 \leq y \leq 3\}$ or the closed interval $[-3, 3]$.
44. Because the graph of f includes the points $(-3, 0)$, $(6, 0)$, and $(10, 0)$, the x -intercepts are -3 , 6 , and 10 .
45. Because the graph of f includes the point $(0, 3)$, the y -intercept is 3 .
46. The graph of the horizontal line $y = \frac{1}{2}$ will intersect the graph of f three times.
47. The graph of the vertical line $x = 5$ will intersect the graph of f once.
48. Because the graph of f includes the point $(x, 3)$ for $0 \leq x \leq 4$, $f(x) = 3$ for $0 \leq x \leq 4$.
49. Because the graph of f includes the points $(-5, -2)$ and $(8, -2)$, $f(x) = -2$ for $x = -5$ and for $x = 8$.
50. The function f is increasing on the intervals $(-6, 0)$ and $(8, 11)$.
51. The function f is decreasing on the interval $(4, 8)$.
52. The function f is constant on the interval $(0, 4)$.
53. The function f is nonincreasing (that is, the function is constant or decreasing) on the interval $(0, 8)$.
54. The function f is nondecreasing (that is, the function is constant or increasing) on the intervals $(-6, 4)$ and $(8, 11)$.
55. Because division by zero is not defined, $x - 6$ cannot be equal to 0 . The domain of g is therefore the set $\{x | x \neq 6\}$.
56. Note that $g(3) = \frac{3+2}{3-6} = -\frac{5}{3}$. Because $g(3) \neq 14$, the point $(3, 14)$ is not on the graph of g .
57. If $x = 4$, then $g(x) = g(4) = \frac{4+2}{4-6} = -3$; therefore, the point $(4, -3)$ is on the graph of g .
58. If $g(x) = 2$, then $\frac{x+2}{x-6} = 2$. Multiplying both sides of this equation by $x - 6$ yields

$$x + 2 = 2(x - 6) = 2x - 12,$$

so that $x = 14$. Accordingly, the point $(14, 2)$ is on the graph of g .

59. The x -intercepts occur when $g(x) = 0$. The value of g can only be zero when its numerator is zero; therefore, $g(x) = 0$ only when $x + 2 = 0$. Thus, the graph of g has only one x -intercept, and this intercept is $\boxed{-2}$.

60. Because $g(0) = \frac{0+2}{0-6} = -\frac{1}{3}$, the y -intercept is $\boxed{-\frac{1}{3}}$.

61. The domain of h is $\{x|x \neq \pm 1\}$, so for every number x in the domain of h , the number $-x$ is also in the domain. Moreover,

$$h(-x) = \frac{-x}{(-x)^2 - 1} = -\frac{x}{x^2 - 1} = -h(x),$$

so that the function h is $\boxed{\text{odd}}$. Because h is an odd function, its graph is symmetric with respect to the $\boxed{\text{origin}}$.

62. The domain of f is all real numbers, so for every number x in the domain of f , the number $-x$ is also in the domain. Moreover,

$$f(-x) = \sqrt[3]{3(-x)^2 + 1} = \sqrt[3]{3x^2 + 1} = f(x),$$

so that the function f is $\boxed{\text{even}}$. Because f is an even function, its graph is symmetric with respect to the $\boxed{y\text{-axis}}$.

63. The domain of G is $\{x|x \geq 0\}$. The number $x = 1$ is in the domain of G , but $x = -1$ is not; therefore, the function G is $\boxed{\text{neither even nor odd}}$. Because G is neither an even nor an odd function, its graph is $\boxed{\text{not symmetric with respect to either the } y\text{-axis or the origin}}$.

64. The domain of F is $\{x|x \neq 0\}$, so for every number x in the domain of F , the number $-x$ is also in the domain. Moreover,

$$F(-x) = \frac{2(-x)}{|-x|} = -\frac{2x}{|x|} = -F(x),$$

so that the function F is $\boxed{\text{odd}}$. Because F is an odd function, its graph is symmetric with respect to the $\boxed{\text{origin}}$.

65. Let $f(x) = -2x^2 + 4$.

- (a) The average rate of change of f from 1 to 2 is

$$\frac{f(2) - f(1)}{2 - 1} = \frac{-4 - 2}{2 - 1} = \frac{-6}{1} = \boxed{-6}.$$

- (b) The average rate of change of f from 1 to 3 is

$$\frac{f(3) - f(1)}{3 - 1} = \frac{-14 - 2}{3 - 1} = \frac{-16}{2} = \boxed{-8}.$$

- (c) The average rate of change of f from 1 to 4 is

$$\frac{f(4) - f(1)}{4 - 1} = \frac{-28 - 2}{4 - 1} = \frac{-30}{3} = \boxed{-10}.$$

- (d) The average rate of change of f from 1 to x for $x \neq 1$ is

$$\frac{f(x) - f(1)}{x - 1} = \frac{-2x^2 + 4 - 2}{x - 1} = \frac{2(1 - x^2)}{x - 1} = \frac{2(1 - x)(1 + x)}{x - 1} = \boxed{-2(1 + x)}.$$

66. Let $s(t) = 20 - 0.8t^2$.

(a) The average rate of change of s from 1 to 4 is

$$\frac{s(4) - s(1)}{4 - 1} = \frac{7.2 - 19.2}{4 - 1} = \frac{-12}{3} = \boxed{-4}.$$

(b) The average rate of change of s from 1 to 3 is

$$\frac{s(3) - s(1)}{3 - 1} = \frac{12.8 - 19.2}{3 - 1} = \frac{-6.4}{2} = \boxed{-3.2}.$$

(c) The average rate of change of s from 1 to 2 is

$$\frac{s(2) - s(1)}{2 - 1} = \frac{16.8 - 19.2}{2 - 1} = \frac{-2.4}{1} = \boxed{-2.4}.$$

(d) The average rate of change of s from 1 to t for $t \neq 1$ is

$$\frac{s(t) - s(1)}{t - 1} = \frac{20 - 0.8t^2 - 19.2}{t - 1} = \frac{0.8(1 - t^2)}{t - 1} = \frac{0.8(1 - t)(1 + t)}{t - 1} = \boxed{-0.8(1 + t)}.$$

67. For $-1 \leq x < 0$, the graph is a line through the points $(-1, 1)$ and $(0, 0)$. The slope of this line is $m = -1$, and the y -intercept is 0; therefore, the equation for this component of the function is $y = -x$. For $0 \leq x \leq 2$, the graph is a line through the points $(0, 0)$ and $(2, 1)$. The slope of this line is $m = \frac{1}{2}$, and the y -intercept is 0; therefore, the equation for this component of the function is $y = \frac{1}{2}x$. Combining these two equations, the definition for this piecewise function is

$$f(x) = \begin{cases} -x, & \text{if } -1 \leq x < 0 \\ \frac{1}{2}x, & \text{if } 0 \leq x \leq 2. \end{cases}$$

The domain of f is the set $\{x | -1 \leq x \leq 2\}$ or the closed interval $[-1, 2]$, and the range is the set $\{y | 0 \leq y \leq 1\}$ or the closed interval $[0, 1]$.

68. For $x \leq 0$, the graph is a line with slope 1 through the origin, and for $0 < x \leq 2$, the graph is a horizontal line at height $y = 1$. The definition for this piecewise function is therefore

$$f(x) = \begin{cases} x, & \text{if } x \leq 0 \\ 1, & \text{if } 0 < x \leq 2. \end{cases}$$

The domain of f is $\{x | x \leq 2\}$ in set notation or $(-\infty, 2]$ in interval notation, and the range is $\{y | y = 1 \text{ or } y \leq 0\}$ in set notation or $(-\infty, 0] \cup \{1\}$ in interval notation.

69. For $x < 1$, the graph is a horizontal line at height $y = -1$; at $x = 1$, the value of the function is 0; and for $1 < x \leq 2$, the graph is a line with slope -1 and x -intercept 2. The definition for this piecewise function is therefore

$$f(x) = \begin{cases} -1, & \text{if } x < 1 \\ 0, & \text{if } x = 1 \\ 2 - x, & \text{if } 1 < x \leq 2. \end{cases}$$

The domain of f is $\{x | x \leq 2\}$ in set notation or $(-\infty, 2]$ in interval notation, and the range is $\{y | y = -1 \text{ or } 0 \leq y < 1\}$ in set notation or $\{-1\} \cup [0, 1)$ in interval notation.

70. For $x < -1$, the graph is a horizontal line at height $y = 2$; at $x = -1$, the value of the function is 0; and for $-1 < x \leq 1$, the graph is a line with slope -2 and y -intercept -1 . The definition for this piecewise function is therefore

$$f(x) = \begin{cases} 2, & \text{if } x < -1 \\ 0, & \text{if } x = -1 \\ -2x - 1, & \text{if } -1 < x \leq 1. \end{cases}$$

The domain of f is $\{x|x \leq 1\}$ in set notation or $(-\infty, 1]$ in interval notation, and the range is $\{y|y = 2 \text{ or } -3 \leq y < 1\}$ in set notation of $[-3, 1) \cup \{2\}$ in interval notation.

71. The definition for this piecewise function is

$$f(x) = \begin{cases} -x^3, & \text{if } -2 < x < 1 \\ 0, & \text{if } x = 1 \\ x^2, & \text{if } 1 < x \leq 3. \end{cases}$$

The domain of f is the set $\{x|-2 < x \leq 3\}$ or the interval $(-2, 3]$, and the range is the set $\{y|-1 < y \leq 9\}$ or the interval $(-1, 9]$.

72. The definition for this piecewise function is

$$f(x) = \begin{cases} x^2 - 1, & \text{if } -3 \leq x \leq 0 \\ x^3, & \text{if } 0 < x \leq 2. \end{cases}$$

The domain of f is the set $\{x|-3 \leq x \leq 2\}$ or the closed interval $[-3, 2]$, and the range is the set $\{y|-1 \leq y \leq 8\}$ or the closed interval $[-1, 8]$.

73. (a) The cost of manufacturing 100 road bikes is

$$C(100) = 0.004(100)^3 - 0.6(100)^2 + 250(100) + 100,500 = 123,500;$$

the cost of manufacturing 101 road bikes is

$$C(101) = 0.004(101)^3 - 0.6(101)^2 + 250(101) + 100,500 \approx 123,750.60.$$

The average rate of change of C from 100 to 101 road bikes is therefore

$$\frac{C(101) - C(100)}{101 - 100} \approx \frac{123,750.60 - 123,500}{1} = \boxed{\$250.60 \text{ per bike}}.$$

- (b) The cost of manufacturing 500 road bikes is

$$C(500) = 0.004(500)^3 - 0.6(500)^2 + 250(500) + 100,500 = 575,500;$$

the cost of manufacturing 501 road bikes is

$$C(501) = 0.004(501)^3 - 0.6(501)^2 + 250(501) + 100,500 \approx 578,155.40.$$

The average rate of change of C from 500 to 501 road bikes is therefore

$$\frac{C(501) - C(500)}{501 - 500} \approx \frac{578,155.40 - 575,500}{1} = \boxed{\$2655.40 \text{ per bike}}.$$

- (c) Answers will vary. One possible interpretation is that the unit cost per road bike increases as the number of road bikes manufactured increases.

74. (a) The cost of producing 500 tons of steel is

$$C(500) = \frac{1}{10}(500)^2 + 5(500) + 1500 = 29000;$$

the cost of producing 501 tons of steel is

$$C(501) = \frac{1}{10}(501)^2 + 5(501) + 1500 = 29105.1;$$

The average rate of change of C from 500 to 501 tons of steel is therefore

$$\frac{C(501) - C(500)}{501 - 500} = \frac{29105.1 - 29000}{1} = \boxed{\$105.10 \text{ per ton}}.$$

- (b) The cost of producing 1000 tons of steel is

$$C(1000) = \frac{1}{10}(1000)^2 + 5(1000) + 1500 = 106,500;$$

the cost of producing 1001 tons of steel is

$$C(1001) = \frac{1}{10}(1001)^2 + 5(1001) + 1500 = 106,705.1;$$

The average rate of change of C from 1000 to 1001 tons of steel is therefore

$$\frac{C(1001) - C(1000)}{1001 - 1000} = \frac{106,705.1 - 106,500}{1} = \boxed{\$205.10 \text{ per ton}}.$$

- (c) Answers will vary. One possible interpretation is that the unit cost per ton of steel increases as the number of tons produced increases.

P.2: Library of Functions; Mathematical Modeling

Concepts and Vocabulary

1. The function $f(x) = x^2$ is **(a) increasing** on the interval $(0, \infty)$.
2. **True**. The floor function $f(x) = \lfloor x \rfloor$ is an example of a step function.
3. **True**. The cube function is odd and is increasing on the interval $(-\infty, \infty)$.
4. **False**. The cube root function is odd, but is increasing on the interval $(-\infty, \infty)$.
5. **False**. The domain and range of the reciprocal function are all real nonzero numbers.
6. A number r for which $f(r) = 0$ is called a **zero** of the function f .
7. If r is a zero of even multiplicity of a function f , the graph of f **(b) touches** the x -axis at r .
8. **True**. The x -intercepts of the graph of a polynomial function are called zeros of the function.
9. **True**. The function $f(x) = [x + \sqrt[3]{x^2 - \pi}]^{2/3}$ is an algebraic function.
10. **False**. The domain of every rational function is the set of all real numbers except those for which the value of the denominator polynomial is zero.

Practice Problems

11. This is the graph of a **cube function (D)**.
12. This is the graph of an **identity function (B)**.
13. This is the graph of a **reciprocal function (F)**.
14. This is the graph of a **constant function (A)**.
15. This is the graph of a **square function (C)**.
16. This is the graph of a **square root function (E)**.
17. This is the graph of an **absolute value function (G)**.
18. This is the graph of a **cube root function (H)**.
19. Let $f(x) = \lfloor 2x \rfloor$. Then:
 - (a) $f(1.2) = \lfloor 2(1.2) \rfloor = \lfloor 2.4 \rfloor = \mathbf{2}$.
 - (b) $f(1.6) = \lfloor 2(1.6) \rfloor = \lfloor 3.2 \rfloor = \mathbf{3}$.
 - (c) $f(-1.8) = \lfloor 2(-1.8) \rfloor = \lfloor -3.6 \rfloor = \mathbf{-4}$.
20. Let $f(x) = \left\lceil \frac{x}{2} \right\rceil$. Then:
 - (a) $f(1.2) = \left\lceil \frac{1.2}{2} \right\rceil = \lceil 0.6 \rceil = \mathbf{1}$.

(b) $f(1.6) = \left\lceil \frac{1.6}{2} \right\rceil = \lceil 0.8 \rceil = \boxed{1}$.

(c) $f(-1.8) = \left\lceil \frac{-1.8}{2} \right\rceil = \lceil -0.9 \rceil = \boxed{0}$.

21. Let $f(x) = 3(x - 7)(x + 4)^3$.

(a) The zeros of f are: $x = 7$ with multiplicity one and $x = -4$ with multiplicity three.

(b) The x -intercepts of the graph of f are the zeros 7 and -4 . The y -intercept is

$$f(0) = 3(0 - 7)(0 + 4)^3 = \boxed{-1344}.$$

(c) Because both x -intercepts are zeros with odd multiplicity, the graph of f crosses the x -axis at each x -intercept.

22. Let $f(x) = 4x(x^2 + 1)(x - 2)^3$.

(a) The zeros of f are: $x = 0$ with multiplicity one and $x = 2$ with multiplicity three. Note that the factor $x^2 + 1$ is never equal to zero for any real number x .

(b) The x -intercepts of the graph of f are the zeros 0 and 2. The y -intercept is

$$f(0) = 4(0)(0^2 + 1)(0 - 2)^3 = \boxed{0}.$$

(c) Because both x -intercepts are zeros with odd multiplicity, the graph of f crosses the x -axis at each x -intercept.

23. The graph of f has x -intercepts of 0, 1, and 2, so the function must have factors of x , $x - 1$, and $x - 2$, which is true for all of the listed functions. Because the graph crosses the x -axis at each x -intercept, the zeros must each have odd multiplicity. This rules out functions **(b)** and **(d)**. Finally, f becomes unbounded in the positive direction as x becomes unbounded in the positive direction, and f becomes unbounded in the negative direction as x becomes unbounded in the negative direction. This rules out function **(a)**. Thus, functions **(c)**, **(e)**, and **(f)** might have the given graph.

24. The graph of f has x -intercepts of 0, 1, and 2, so the function must have factors of x , $x - 1$, and $x - 2$, which is true for all of the listed functions. Because the graph crosses the x -axis at $x = 0$ and at $x = 2$ but just touches the x -axis at $x = 1$, the zeros 0 and 2 must have odd multiplicity while the zero 1 must have even multiplicity. This rules out functions **(a)**, **(b)**, and **(d)**. Finally, f becomes unbounded in the positive direction as x becomes unbounded in either direction. Each of the remaining functions satisfies this condition. Thus, functions **(c)**, **(e)**, and **(f)** might have the given graph.

25. The domain of R is the set $\{x | x \neq -3\}$. Because 0 is in the domain of R and $R(0) = 0$, the y -intercept is 0. The zeros of R are solutions of the equation $5x^2 = 0$, or $x = 0$. Because 0 is in the domain of R , the x -intercept is 0. Thus, the only intercept is $(0, 0)$.

26. The domain of H is the set $\{x | x \neq 2, x \neq -4\}$. Because 0 is in the domain of H and $H(0) = 0$, the y -intercept is 0. The zeros of H are solutions of the equation $-4x^2 = 0$, or $x = 0$. Because 0 is in the domain of H , the x -intercept is 0. Thus, the only intercept is $(0, 0)$.

27. Because the denominator $x^2 + 4$ is never equal to zero for any real number x , the domain of R is the set of all real numbers or the interval $(-\infty, \infty)$. Because 0 is in the domain of R and $R(0) = 0$, the y -intercept is 0. The zeros of R are solutions of the equation $3x^2 - x = x(3x - 1) = 0$, or $x = 0$ and $x = \frac{1}{3}$. Because both 0 and $\frac{1}{3}$ are in the domain of R , the x -intercepts are 0 and $\frac{1}{3}$. Thus, the intercepts are $(0, 0)$ and $\left(\frac{1}{3}, 0\right)$.

28. The domain of R is the set $\{x|x \neq \pm 3\}$. Because 0 is in the domain of R and $R(0) = \frac{1}{2}$, the y -intercept is $\frac{1}{2}$. The zeros of R are solutions of the equation $3(x^2 - x - 6) = 3(x - 3)(x + 2) = 0$, or $x = 3$ and $x = -2$. However, $x = 3$ is not in the domain of R , so the only x -intercept is -2 . Thus, the intercepts

are $(-2, 0)$ and $(0, \frac{1}{2})$

29. (a) Let $A(x)$ denote the area of the rectangles as a function of x . From the diagram, each rectangle has length x and height y . Because the point (x, y) lies on the graph of $y = 16 - x^2$, it follows that the height of each rectangle is $16 - x^2$. Therefore,

$$A(x) = xy = x(16 - x^2) = 16x - x^3.$$

- (b) Because the point (x, y) must lie in the first quadrant, $x \geq 0$. As y must also be greater than or equal to 0, x can only be as large as the positive zero of $16 - x^2$. Thus, the domain of A is the set $\{x|0 \leq x \leq 4\}$ or the closed interval $[0, 4]$.
30. (a) Let $A(x)$ denote the area of the rectangles as a function of x . From the diagram, each rectangle has length $2x$ and height y . Because the point (x, y) is in the first quadrant and lies on the graph of a circle of radius 2 centered at the origin, whose equation is $x^2 + y^2 = 4$, it follows that the height of each rectangle is $y = \sqrt{4 - x^2}$. Therefore,

$$A(x) = 2xy = 2x\sqrt{4 - x^2}.$$

- (b) Let $p(x)$ denote the perimeter of the rectangles as a function of x . From the diagram, each rectangle has length $2x$ and height y . Because the point (x, y) is in the first quadrant and lies on the graph of a circle of radius 2 centered at the origin, whose equation is $x^2 + y^2 = 4$, it follows that the height of each rectangle is $y = \sqrt{4 - x^2}$. Therefore,

$$p(x) = 2(2x) + 2y = 4x + 2\sqrt{4 - x^2}.$$

31. (a) A scatter plot of the data is shown below. The pattern in the points suggests a quadratic relationship between the height of the ball and the horizontal distance traveled.

- (b) Using the QuadReg function on a TI-84 Plus calculator yields

$$h(x) = -0.0037x^2 + 1.03x + 5.7$$

as the quadratic function that best fits these data. The ball will hit the ground when $h(x) = 0$. Using the quadratic formula, this will happen when

$$\begin{aligned} x &= \frac{-1.03 \pm \sqrt{(1.03)^2 - 4(-0.0037)(5.7)}}{2(-0.0037)} = \frac{-1.03 \pm 1.07}{-0.0074} \\ &\approx 283.8, -5.4 \end{aligned}$$

The value $x = -5.4$ may be disregarded. The ball will therefore hit the ground after traveling a horizontal distance of approximately 283.8 feet.

- (c) When the ball has traveled a horizontal distance of 10 feet, the height will be approximately

$$h(10) = -0.0037(10)^2 + 1.03(10) + 5.7 = 15.63 \text{ feet}.$$

32. (a) A scatter plot of the data is shown below. The pattern in the points suggests a cubic relationship between the percentage of the population without a high school diploma and age.

- (b) Using the CubicReg function on a TI-84 Plus calculator yields

$$P(x) = 0.00026x^3 - 0.0303x^2 + 1.0877x - 0.5071$$

as the cubic function that best fits these data.

- (c) Based on these data, the approximate percentage of 35-year olds who do not have a high school diploma is

$$P(35) = 0.00026(35)^3 - 0.0303(35)^2 + 1.0877(35) - 0.5071 \approx 11.59.$$

P.3: Operations on Functions; Graphing Techniques

Concepts and Vocabulary

1. If the domain of function f is $\{x|0 \leq x \leq 7\}$ and the domain of function g is $\{x|-2 \leq x \leq 5\}$, then the domain of the sum function $f + g$ is $\{x|0 \leq x \leq 5\}$; that is, the intersection of the domains of f and g .
2. **False**. If f and g are functions, then the domain of $\frac{f}{g}$ consists of all numbers x that are in the domains of both f and g , but excluding the numbers x for which $g(x) = 0$.
3. **True**. The domain of $(f \cdot g)(x)$ consists of the numbers x that are in the domains of both f and g .
4. **False**. The domain of the composite function $(f \circ g)(x)$ is the set of all numbers x in the domain of g for which $g(x)$ is in the domain of f .
5. **True**. The graph of $y = -f(x)$ is the reflection of the graph of $y = f(x)$ about the x -axis.
6. **False**. To obtain the graph of $y = f(x + 2) - 3$, shift the graph of $y = f(x)$ horizontally to the left 2 units and vertically down 3 units.
7. **True**. Suppose the x -intercepts of the graph of the function f are -3 and 2 . Then the x -intercepts of the graph of $y = 2f(x)$ are -3 and 2 .
8. Suppose that the graph of a function f is known. Then the graph of the function $y = f(x - 2)$ can be obtained by a **horizontal** shift of the graph of f to the **right** a distance of 2 units.
9. Suppose that the graph of a function f is known. Then the graph of the function $y = f(-x)$ can be obtained by a reflection about the **y** -axis of the graph of f .
10. Suppose the x -intercepts of the graph of the function f are -2 , 1 , and 5 . The x -intercepts of $y = f(x + 3)$ are -5 , -2 , and 2 .

Practice Problems

11. Let $f(x) = 3x + 4$ and $g(x) = 2x - 3$. Note the domain of both f and g is the set of all real numbers.
 - (a) $(f + g)(x) = f(x) + g(x) = 3x + 4 + 2x - 3 = 5x + 1$. The domain of this function is the set of all real numbers or the interval $(-\infty, \infty)$.
 - (b) $(f - g)(x) = f(x) - g(x) = 3x + 4 - (2x - 3) = x + 7$. The domain of this function is the set of all real numbers or the interval $(-\infty, \infty)$.
 - (c) $(f \cdot g)(x) = f(x)g(x) = (3x + 4)(2x - 3) = 6x^2 - x - 12$. The domain of this function is the set of all real numbers or the interval $(-\infty, \infty)$.
 - (d) $\left(\frac{f}{g}\right)(x) = \frac{f(x)}{g(x)} = \frac{3x + 4}{2x - 3}$. The domain of this function is the set $\{x|x \neq \frac{3}{2}\}$.
12. Let $f(x) = 1 + \frac{1}{x}$ and $g(x) = \frac{1}{x}$. Note the domain of both f and g is the set $\{x|x \neq 0\}$.
 - (a) $(f + g)(x) = f(x) + g(x) = 1 + \frac{1}{x} + \frac{1}{x} = 1 + \frac{2}{x}$. The domain of this function is the set $\{x|x \neq 0\}$.

- (b) $(f - g)(x) = f(x) - g(x) = 1 + \frac{1}{x} - \frac{1}{x} = \boxed{1}$. The domain of this function is the set $\boxed{\{x|x \neq 0\}}$.
- (c) $(f \cdot g)(x) = f(x)g(x) = \left(1 + \frac{1}{x}\right) \frac{1}{x} = \boxed{\frac{1}{x} + \frac{1}{x^2}}$. The domain of this function is the set $\boxed{\{x|x \neq 0\}}$.
- (d) $\left(\frac{f}{g}\right)(x) = \frac{f(x)}{g(x)} = \frac{1 + \frac{1}{x}}{\frac{1}{x}} = \boxed{x + 1}$. The domain of this function is the set $\boxed{\{x|x \neq 0\}}$.
13. Let $f(x) = \sqrt{x+1}$ and $g(x) = \frac{2}{x}$. Note the domain of f is the set $\{x|x \geq -1\}$ and the domain of g is the set $\{x|x \neq 0\}$.

- (a) $(f + g)(x) = f(x) + g(x) = \boxed{\sqrt{x+1} + \frac{2}{x}}$. The domain of this function is the set $\boxed{\{x|-1 \leq x < 0\} \cup \{x|x > 0\}}$.
- (b) $(f - g)(x) = f(x) - g(x) = \boxed{\sqrt{x+1} - \frac{2}{x}}$. The domain of this function is the set $\boxed{\{x|-1 \leq x < 0\} \cup \{x|x > 0\}}$.
- (c) $(f \cdot g)(x) = f(x)g(x) = \sqrt{x+1} \cdot \frac{2}{x} = \boxed{\frac{2\sqrt{x+1}}{x}}$. The domain of this function is the set $\boxed{\{x|-1 \leq x < 0\} \cup \{x|x > 0\}}$.
- (d) $\left(\frac{f}{g}\right)(x) = \frac{f(x)}{g(x)} = \frac{\sqrt{x+1}}{\frac{2}{x}} = \boxed{\frac{x}{2}\sqrt{x+1}}$. The domain of this function is the set $\boxed{\{x|-1 \leq x < 0\} \cup \{x|x > 0\}}$.

14. Let $f(x) = |x|$ and $g(x) = x$. Note the domain of both f and g is the set of all real numbers.

- (a) $(f + g)(x) = f(x) + g(x) = \boxed{|x| + x}$. The domain of this function is the set of $\boxed{\text{all real numbers}}$ or the interval $\boxed{(-\infty, \infty)}$.
- (b) $(f - g)(x) = f(x) - g(x) = \boxed{|x| - x}$. The domain of this function is the set of $\boxed{\text{all real numbers}}$ or the interval $\boxed{(-\infty, \infty)}$.
- (c) $(f \cdot g)(x) = f(x)g(x) = \boxed{|x|x}$. The domain of this function is the set of $\boxed{\text{all real numbers}}$ or the interval $\boxed{(-\infty, \infty)}$.
- (d) $\left(\frac{f}{g}\right)(x) = \frac{f(x)}{g(x)} = \boxed{\frac{|x|}{x}}$. The domain of this function is the set $\boxed{\{x|x \neq 0\}}$.

15. Let $f(x) = 2x$ and $g(x) = 3x^2 + 1$.

- (a) $(f \circ g)(4) = f(g(4)) = f(49) = \boxed{98}$.
- (b) $(g \circ f)(2) = g(f(2)) = g(4) = \boxed{49}$.
- (c) $(f \circ f)(1) = f(f(1)) = f(2) = \boxed{4}$.
- (d) $(g \circ g)(0) = g(g(0)) = g(1) = \boxed{4}$.

16. Let $f(x) = \frac{3}{x+1}$ and $g(x) = \sqrt{x}$.

- (a) $(f \circ g)(4) = f(g(4)) = f(2) = \boxed{1}$.

- (b) $(g \circ f)(2) = g(f(2)) = g(1) = \boxed{1}$.
- (c) $(f \circ f)(1) = f(f(1)) = f\left(\frac{3}{2}\right) = \boxed{\frac{6}{5}}$.
- (d) $(g \circ g)(0) = g(g(0)) = g(0) = \boxed{0}$.
17. (a) $(f \circ g)(1) = f(g(1)) = f(0) = \boxed{-1}$.
- (b) $(f \circ g)(-1) = f(g(-1)) = f(0) = \boxed{-1}$.
- (c) $(g \circ f)(-1) = g(f(-1)) = g(-3) = \boxed{8}$.
- (d) $(g \circ f)(1) = g(f(1)) = g(3) = \boxed{8}$.
- (e) $(g \circ g)(-2) = g(g(-2)) = g(3) = \boxed{8}$.
- (f) $(f \circ f)(-1) = f(f(-1)) = f(-3) = \boxed{-7}$.
18. (a) $(f \circ g)(1) = f(g(1)) = f(0) = \boxed{5}$.
- (b) $(f \circ g)(2) = f(g(2)) = f(-3) = \boxed{11}$.
- (c) $(g \circ f)(2) = g(f(2)) = g(1) = \boxed{0}$.
- (d) $(g \circ f)(3) = g(f(3)) = g(-1) = \boxed{0}$.
- (e) $(g \circ g)(1) = g(g(1)) = g(0) = \boxed{1}$.
- (f) $(f \circ f)(3) = f(f(3)) = f(-1) = \boxed{7}$.
19. (a) $(g \circ f)(-1) = g(f(-1)) = g(1) = \boxed{4}$.
- (b) $(g \circ f)(6) = g(f(6)) = g(2) = \boxed{2}$.
- (c) $(f \circ g)(6) = f(g(6)) = f(5) = \boxed{1}$.
- (d) $(f \circ g)(4) = f(g(4)) = f(2) = \boxed{-2}$.
20. (a) $(g \circ f)(1) = g(f(1)) = g(-1) = \boxed{3}$.
- (b) $(g \circ f)(5) = g(f(5)) = g(1) = \boxed{4}$.
- (c) $(f \circ g)(7) = f(g(7)) = f(5) = \boxed{1}$.
- (d) $(f \circ g)(2) = f(g(2)) = f(2) = \boxed{-2}$.
21. Let $f(x) = 3x + 1$ and $g(x) = 8x$. Note the domain of both f and g is the set of all real numbers.
- (a) $(f \circ g)(x) = f(g(x)) = f(8x) = 3(8x) + 1 = \boxed{24x + 1}$. The domain of this function is the set of all real numbers or the interval $(-\infty, \infty)$.
- (b) $(g \circ f)(x) = g(f(x)) = g(3x + 1) = 8(3x + 1) = \boxed{24x + 8}$. The domain of this function is the set of all real numbers or the interval $(-\infty, \infty)$.
- (c) $(f \circ f)(x) = f(f(x)) = f(3x + 1) = 3(3x + 1) + 1 = \boxed{9x + 4}$. The domain of this function is the set of all real numbers or the interval $(-\infty, \infty)$.
- (d) $(g \circ g)(x) = g(g(x)) = g(8x) = 8(8x) = \boxed{64x}$. The domain of this function is the set of all real numbers or the interval $(-\infty, \infty)$.
22. Let $f(x) = -x$ and $g(x) = 2x - 4$. Note the domain of both f and g is the set of all real numbers.

- (a) $(f \circ g)(x) = f(g(x)) = f(2x - 4) = -(2x - 4) = 4 - 2x$. The domain of this function is the set of all real numbers or the interval $(-\infty, \infty)$.
- (b) $(g \circ f)(x) = g(f(x)) = g(-x) = 2(-x) - 4 = -2x - 4$. The domain of this function is the set of all real numbers or the interval $(-\infty, \infty)$.
- (c) $(f \circ f)(x) = f(f(x)) = f(-x) = -(-x) = x$. The domain of this function is the set of all real numbers or the interval $(-\infty, \infty)$.
- (d) $(g \circ g)(x) = g(g(x)) = g(2x - 4) = 2(2x - 4) - 4 = 4x - 12$. The domain of this function is the set of all real numbers or the interval $(-\infty, \infty)$.
23. Let $f(x) = x^2 + 1$ and $g(x) = \sqrt{x - 1}$. Note the domain of f is the set of all real numbers and the domain of g is the set $\{x|x \geq 1\}$.
- (a) $(f \circ g)(x) = f(g(x)) = f(\sqrt{x - 1}) = (\sqrt{x - 1})^2 + 1 = x$. The domain of $f \circ g$ begins with the domain of g : $\{x|x \geq 1\}$. Because the domain of f is the set of all real numbers, any value of $g(x)$ will be in the domain of f . Therefore, the domain of $f \circ g$ is the set $\{x|x \geq 1\}$.
- (b) $(g \circ f)(x) = g(f(x)) = g(x^2 + 1) = \sqrt{x^2 + 1 - 1} = |x|$. The domain of $g \circ f$ begins with the domain of f : the set of all real numbers. Because the domain of g is the set $\{x|x \geq 1\}$ and the value of $f(x)$ is always a number greater than or equal to one, it follows that the value of $f(x)$ is always in the domain of g . Therefore, the domain of $g \circ f$ is the set of all real numbers or the interval $(-\infty, \infty)$.
- (c) $(f \circ f)(x) = f(f(x)) = f(x^2 + 1) = (x^2 + 1)^2 + 1 = x^4 + 2x^2 + 2$. The domain of this function is the set of all real numbers or the interval $(-\infty, \infty)$.
- (d) $(g \circ g)(x) = g(g(x)) = g(\sqrt{x - 1}) = \sqrt{\sqrt{x - 1} - 1}$. The domain of $g \circ g$ begins with the domain of g : $\{x|x \geq 1\}$. Next, the value of $g(x) = \sqrt{x - 1}$ must be in the domain of g ; that is, the inequality $\sqrt{x - 1} \geq 1$ must be satisfied. Solving this inequality yields $x - 1 \geq 1$, or $x \geq 2$. Therefore, the domain of $g \circ g$ is the set $\{x|x \geq 2\}$.
24. Let $f(x) = 2x + 3$ and $g(x) = \sqrt{x}$. Note the domain of f is the set of all real numbers and the domain of g is the set $\{x|x \geq 0\}$.
- (a) $(f \circ g)(x) = f(g(x)) = f(\sqrt{x}) = 2\sqrt{x} + 3$. The domain of $f \circ g$ begins with the domain of g : $\{x|x \geq 0\}$. Because the domain of f is the set of all real numbers, any value of $g(x)$ will be in the domain of f . Therefore, the domain of $f \circ g$ is the set $\{x|x \geq 0\}$.
- (b) $(g \circ f)(x) = g(f(x)) = g(2x + 3) = \sqrt{2x + 3}$. The domain of $g \circ f$ begins with the domain of f : the set of all real numbers. Next, the value of $f(x) = 2x + 3$ must be in the domain of g ; that is, the inequality $2x + 3 \geq 0$ must be satisfied. Solving this inequality yields $x \geq -\frac{3}{2}$. Therefore, the domain of $g \circ f$ is the set $\{x|x \geq -\frac{3}{2}\}$.
- (c) $(f \circ f)(x) = f(f(x)) = f(2x + 3) = 2(2x + 3) + 3 = 4x + 10$. The domain of this function is the set of all real numbers or the interval $(-\infty, \infty)$.
- (d) $(g \circ g)(x) = g(g(x)) = g(\sqrt{x}) = \sqrt{\sqrt{x}} = \sqrt[4]{x}$. The domain of $g \circ g$ begins with the domain of g : $\{x|x \geq 0\}$. Next, the value of $g(x) = \sqrt{x}$ must be in the domain of g ; that is, the inequality $\sqrt{x} \geq 0$ must be satisfied. Solving this inequality yields $x \geq 0$. Therefore, the domain of $g \circ g$ is the set $\{x|x \geq 0\}$.

25. Let $f(x) = \frac{x}{x-1}$ and $g(x) = \frac{2}{x}$. Note the domain of f is the set $\{x|x \neq 1\}$ and the domain of g is the set $\{x|x \neq 0\}$.

(a) $(f \circ g)(x) = f(g(x)) = f\left(\frac{2}{x}\right) = \frac{\frac{2}{x}}{\frac{2}{x}-1} = \boxed{\frac{2}{2-x}}$. The domain of $f \circ g$ begins with the domain of g : $\{x|x \neq 0\}$. Next, the value of $g(x)$ must be in the domain of f ; that is, the value of $\frac{2}{x}$ cannot be equal to 1. This means that x cannot be equal to 2. The domain of $f \circ g$ is therefore the set $\boxed{\{x|x \neq 0, x \neq 2\}}$.

(b) $(g \circ f)(x) = g(f(x)) = g\left(\frac{x}{x-1}\right) = \frac{2}{\frac{x}{x-1}} = \boxed{\frac{2(x-1)}{x}}$. The domain of $g \circ f$ begins with the domain of f : $\{x|x \neq 1\}$. Next, the value of $f(x)$ must be in the domain of g ; that is, the value of $\frac{x}{x-1}$ cannot be equal to 0. This means that x cannot be equal to 0. The domain of $g \circ f$ is therefore the set $\boxed{\{x|x \neq 0, x \neq 1\}}$.

(c) $(f \circ f)(x) = f(f(x)) = f\left(\frac{x}{x-1}\right) = \frac{\frac{x}{x-1}}{\frac{x}{x-1}-1} = \frac{x}{x-(x-1)} = \boxed{x}$. The domain of $f \circ f$ begins with the domain of f : $\{x|x \neq 1\}$. Next, the value of $f(x)$ must be in the domain of f ; that is, the value of $\frac{x}{x-1}$ cannot be equal to 1. The equation

$$\frac{x}{x-1} = 1,$$

however, has no solution. The domain of $f \circ f$ is therefore the set $\boxed{\{x|x \neq 1\}}$.

(d) $(g \circ g)(x) = g(g(x)) = g\left(\frac{2}{x}\right) = \frac{2}{\frac{2}{x}} = \boxed{x}$. The domain of $g \circ g$ begins with the domain of g : $\{x|x \neq 0\}$. Next, the value of $g(x)$ must be in the domain of g ; that is, the value of $\frac{2}{x}$ cannot be equal to 0. The equation

$$\frac{2}{x} = 0,$$

however, has no solution. The domain of $g \circ g$ is therefore the set $\boxed{\{x|x \neq 0\}}$.

26. Let $f(x) = \frac{1}{x+3}$ and $g(x) = -\frac{2}{x}$. Note the domain of f is the set $\{x|x \neq -3\}$ and the domain of g is the set $\{x|x \neq 0\}$.

(a) $(f \circ g)(x) = f(g(x)) = f\left(-\frac{2}{x}\right) = \frac{1}{-\frac{2}{x}+3} = \boxed{\frac{x}{-2+3x}}$. The domain of $f \circ g$ begins with the domain of g : $\{x|x \neq 0\}$. Next, the value of $g(x)$ must be in the domain of f ; that is, the value of $-\frac{2}{x}$ cannot be equal to -3. This means that x cannot be equal to $\frac{2}{3}$. The domain of $f \circ g$ is therefore the set $\boxed{\{x|x \neq 0, x \neq \frac{2}{3}\}}$.

(b) $(g \circ f)(x) = g(f(x)) = g\left(\frac{1}{x+3}\right) = -\frac{2}{\frac{1}{x+3}} = \boxed{-2(x+3)}$. The domain of $g \circ f$ begins with the domain of f : $\{x|x \neq -3\}$. Next, the value of $f(x)$ must be in the domain of g ; that is, the value of $\frac{1}{x+3}$ cannot be equal to 0. The equation

$$\frac{1}{x+3} = 0,$$

however, has no solution. The domain of $g \circ f$ is therefore the set $\boxed{\{x|x \neq -3\}}$.

(c) $(f \circ f)(x) = f(f(x)) = f\left(\frac{1}{x+3}\right) = \frac{1}{\frac{1}{x+3} + 3} = \frac{x+3}{1+3(x+3)} = \frac{x+3}{3x+10}$. The domain of $f \circ f$ begins with the domain of f : $\{x|x \neq -3\}$. Next, the value of $f(x)$ must be in the domain of f ; that is, the value of $\frac{1}{x+3}$ cannot be equal to -3 . This means that x cannot be equal to $-\frac{10}{3}$. The domain of $f \circ f$ is therefore the set $\{x|x \neq -3, x \neq -\frac{10}{3}\}$.

(d) $(g \circ g)(x) = g(g(x)) = g\left(-\frac{2}{x}\right) = -\frac{2}{-\frac{2}{x}} = x$. The domain of $g \circ g$ begins with the domain of g : $\{x|x \neq 0\}$. Next, the value of $g(x)$ must be in the domain of g ; that is, the value of $-\frac{2}{x}$ cannot be equal to 0. The equation

$$-\frac{2}{x} = 0,$$

however, has no solution. The domain of $g \circ g$ is therefore the set $\{x|x \neq 0\}$.

27. Let $f(x) = x^4$ and $g(x) = 2x + 3$. Then

$$(f \circ g)(x) = f(g(x)) = f(2x + 3) = (2x + 3)^4 = F(x).$$

28. Let $f(x) = x^3$ and $g(x) = 1 + x^2$. Then

$$(f \circ g)(x) = f(g(x)) = f(1 + x^2) = (1 + x^2)^3 = F(x).$$

29. Let $f(x) = \sqrt{x}$ and $g(x) = x^2 + 1$. Then

$$(f \circ g)(x) = f(g(x)) = f(x^2 + 1) = \sqrt{x^2 + 1} = F(x).$$

30. Let $f(x) = \sqrt{x}$ and $g(x) = 1 - x^2$. Then

$$(f \circ g)(x) = f(g(x)) = f(1 - x^2) = \sqrt{1 - x^2} = F(x).$$

31. Let $f(x) = |x|$ and $g(x) = 2x + 1$. Then

$$(f \circ g)(x) = f(g(x)) = f(2x + 1) = |2x + 1| = F(x).$$

32. Let $f(x) = |x|$ and $g(x) = 2x^2 + 3$. Then

$$(f \circ g)(x) = f(g(x)) = f(2x^2 + 3) = |2x^2 + 3| = F(x).$$

33. The graph of $f(x) = x^3 + 2$ can be obtained from the graph of $y = x^3$ by shifting vertically up 2 units. In the figure below, the graph of $y = x^3$ is represented by the dashed curve, and the graph of $y = x^3 + 2$ is represented by the solid curve.

34. The graph of $g(x) = x^3 - 1$ can be obtained from the graph of $y = x^3$ by shifting vertically down 1 unit. In the figure below, the graph of $y = x^3$ is represented by the dashed curve, and the graph of $y = x^3 - 1$ is represented by the solid curve.

35. The graph of $h(x) = \sqrt{x-2}$ can be obtained from the graph of $y = \sqrt{x}$ by shifting horizontally right 2 units. In the figure below, the graph of $y = \sqrt{x}$ is represented by the dashed curve, and the graph of $y = \sqrt{x-2}$ is represented by the solid curve.

36. The graph of $f(x) = \sqrt{x+1}$ can be obtained from the graph of $y = \sqrt{x}$ by shifting horizontally left 1 unit. In the figure below, the graph of $y = \sqrt{x}$ is represented by the dashed curve, and the graph of $y = \sqrt{x+1}$ is represented by the solid curve.

37. The graph of $g(x) = 4\sqrt{x}$ can be obtained from the graph of $y = \sqrt{x}$ by stretching vertically by a factor of 4. In the figure below, the graph of $y = \sqrt{x}$ is represented by the dashed curve, and the graph of $y = 4\sqrt{x}$ is represented by the solid curve.

38. The graph of $f(x) = \frac{1}{2}\sqrt{x}$ can be obtained from the graph of $y = \sqrt{x}$ by compressing vertically by a factor of $\frac{1}{2}$. In the figure below, the graph of $y = \sqrt{x}$ is represented by the dashed curve, and the graph of $y = \frac{1}{2}\sqrt{x}$ is represented by the solid curve.

39. The graph of $f(x) = (x - 1)^3 + 2$ can be obtained from the graph of $y = x^3$ by shifting horizontally right 1 unit and then shifting vertically up 2 units. In the figure below at the left, the graph of $y = x^3$ is represented by the dashed curve, and the graph of $y = (x - 1)^3$ is represented by the dash-dot curve. In the figure below at the right, the graph of $y = (x - 1)^3$ is represented by the dash-dot curve, and the graph of $y = (x - 1)^3 + 2$ is represented by the solid curve.

40. The graph of $g(x) = 3(x - 2)^3 + 1$ can be obtained from the graph of $y = x^3$ by shifting horizontally right 2 units, then stretching vertically by a factor of 3 and finally shifting vertically up 1 unit. In the figure below at the top left, the graph of $y = x^3$ is represented

by the dashed curve, and the graph of $y = (x - 2)^3$ is represented by the dash-dot curve. In the figure below at the top right, the graph of $y = (x - 2)^3$ is represented by the dash-dot curve, and the graph of $y = 3(x - 2)^3$ is represented by the dotted curve. In the bottom figure, the graph of $y = 3(x - 2)^3$ is represented by the dotted curve, and the graph of $y = 3(x - 2)^3 + 1$ is represented by the solid curve.

41. The graph of $h(x) = \frac{1}{2x}$ can be obtained from the graph of $y = \frac{1}{x}$ by compressing vertically by a factor of $\frac{1}{2}$. In the figure below, the graph of $y = \frac{1}{x}$ is represented by the dashed curve, and the graph of $y = \frac{1}{2x}$ is represented by the solid curve.

42. The graph of $f(x) = \frac{4}{x} + 2$ can be obtained from the graph of $y = \frac{1}{x}$ by stretching vertically by a factor of 4 and then shifting vertically up 2 units. In the figure below at the left, the graph of $y = \frac{1}{x}$ is represented by the dashed curve, and the graph of $y = \frac{4}{x}$ is represented

by the dash-dot curve. In the figure below at the right, the graph of $y = \frac{4}{x}$ is represented by the dash-dot curve, and the graph of $y = \frac{4}{x} + 2$ is represented by the solid curve.

43. First note that because $|-t| = |t|$, the function G can be written as $G(x) = 2|-(x-1)| = 2|x-1|$. The graph of G can therefore be obtained from the graph of $y = |x|$ by shifting horizontally right 1 unit and then stretching vertically by a factor of 2. In the figure below at the left, the graph of $y = |x|$ is represented by the dashed curve, and the graph of $y = |x-1|$ is represented by the dash-dot curve. In the figure below at the right, the graph of $y = |x-1|$ is represented by the dash-dot curve, and the graph of $y = 2|x-1|$ is represented by the solid curve.

44. The graph of $g(x) = -(x+1)^3 - 1$ can be obtained from the graph of $y = x^3$ by shifting horizontally left 1 unit, then reflecting about the x -axis and finally shifting vertically down 1 unit. In the figure below at the top left, the graph of $y = x^3$ is represented by the dashed curve, and the graph of $y = (x+1)^3$ is represented by the dash-dot curve. In the figure below at the top right, the graph of $y = (x+1)^3$ is represented by the dash-dot curve, and the graph of $y = -(x+1)^3$ is represented by the dotted curve. In the bottom figure, the graph of $y = -(x+1)^3$ is represented by the dotted curve, and the graph of $y = -(x+1)^3 - 1$ is represented by the solid curve.

45. The graph of $g(x) = -4\sqrt{x-1}$ can be obtained from the graph of $y = \sqrt{x}$ by shifting horizontally right 1 unit, then stretching vertically by a factor of 4, and finally reflecting about the x -axis. In the figure below at the top left, the graph of $y = \sqrt{x}$ is represented by the dashed curve, and the graph of $y = \sqrt{x-1}$ is represented by the dash-dot curve. In the figure below at the top right, the graph of $y = \sqrt{x-1}$ is represented by the dash-dot curve, and the graph of $y = 4\sqrt{x-1}$ is represented by the dotted curve. In the bottom figure, the graph of $y = 4\sqrt{x-1}$ is represented by the dotted curve, and the graph of $y = -4\sqrt{x-1}$ is represented by the solid curve.

46. The graph of $f(x) = 4\sqrt{2-x} = 4\sqrt{-x+2}$ can be obtained from the graph of $y = \sqrt{x}$ by shifting horizontally left 2 units, then reflecting about the y -axis, and finally stretching vertically by a factor of 4. In the figure below at the top left, the graph of $y = \sqrt{x}$ is represented by the dashed curve, and the graph of $y = \sqrt{x+2}$ is represented by the dash-dot curve. In the figure below at the top right, the graph of $y = \sqrt{x+2}$ is represented by the dash-dot curve, and the graph of $y = \sqrt{-x+2}$ is represented by the dotted curve. In the bottom figure, the graph of $y = \sqrt{-x+2}$ is represented by the dotted curve, and the graph of $y = 4\sqrt{-x+2}$ is represented by the solid curve.

47. (a) The graph of $F(x) = f(x) + 3$ can be obtained from the graph of f by shifting vertically up 3 units. In the figure below, the graph of f is represented by the dashed curve, and the graph of F is represented by the solid curve.

- (b) The graph of $G(x) = f(x + 2)$ can be obtained from the graph of f by shifting horizontally left 2 units. In the figure below, the graph of f is represented by the dashed curve, and the graph of G is represented by the solid curve.

- (c) The graph of $P(x) = -f(x)$ can be obtained from the graph of f by reflecting about the x -axis. In the figure below, the graph of f is represented by the dashed curve, and the graph of P is represented by the solid curve.

- (d) The graph of $H(x) = f(x + 1) - 2$ can be obtained from the graph of f by shifting horizontally left 1 unit and vertically down 2 units. In the figure below, the graph of f is represented by the dashed curve, and the graph of H is represented by the solid curve.

- (e) The graph of $Q(x) = \frac{1}{2}f(x)$ can be obtained from the graph of f by compressing vertically by a factor of $\frac{1}{2}$. In the figure below, the graph of f is represented by the dashed curve, and the graph of Q is represented by the solid curve.

- (f) The graph of $g(x) = f(-x)$ can be obtained from the graph of f by reflecting about the y -axis. In the figure below, the graph of f is represented by the dashed curve, and the graph of g is represented by the solid curve.

- (g) The graph of $h(x) = f(2x)$ can be obtained from the graph of f by compressing horizontally by a factor of $\frac{1}{2}$. In the figure below, the graph of f is represented by the dashed curve, and the graph of h is represented by the solid curve.

48. (a) The graph of $F(x) = f(x) + 3$ can be obtained from the graph of f by shifting vertically up 3 units. In the figure below, the graph of f is represented by the dashed curve, and the graph of F is represented by the solid curve.

- (b) The graph of $G(x) = f(x + 2)$ can be obtained from the graph of f by shifting horizontally left 2 units. In the figure below, the graph of f is represented by the dashed curve, and the graph of G is represented by the solid curve.

- (c) The graph of $P(x) = -f(x)$ can be obtained from the graph of f by reflecting about the x -axis. In the figure below, the graph of f is represented by the dashed curve, and the graph of P is represented by the solid curve.

- (d) The graph of $H(x) = f(x + 1) - 2$ can be obtained from the graph of f by shifting horizontally left 1 unit and vertically down 2 units. In the figure below, the graph of f is represented by the dashed curve, and the graph of H is represented by the solid curve.

- (e) The graph of $Q(x) = \frac{1}{2}f(x)$ can be obtained from the graph of f by compressing vertically by a factor of $\frac{1}{2}$. In the figure below, the graph of f is represented by the dashed curve, and the graph of Q is represented by the solid curve.

- (f) The graph of $g(x) = f(-x)$ can be obtained from the graph of f by reflecting about the y -axis. Because the graph of f is symmetric with respect to the y -axis, the graphs of f and g coincide.

- (g) The graph of $h(x) = f(2x)$ can be obtained from the graph of f by compressing horizontally by a factor of $\frac{1}{2}$. In the figure below, the graph of f is represented by the dashed curve, and the graph of h is represented by the solid curve.

49. (a) The graph of $T(l)$ is shown below:

- (b) The graphs of $T(l + 1)$, $T(l + 2)$, and $T(l + 3)$ are shown below:

- (c) Answers will vary, but one interpretation follows. As seen in the graphs for parts (a) and (b), the period T is an increasing function of the length l . Adding to the length of the pendulum therefore increases the period. Algebraically, observe that

$$l + 1 = l \left(1 + \frac{1}{l} \right),$$

so that

$$T(l+1) = 2\pi \sqrt{\frac{l+1}{g}} = \sqrt{1 + \frac{1}{l}} \cdot 2\pi \sqrt{\frac{l}{g}} = \sqrt{1 + \frac{1}{l}} T(l).$$

The factor $\sqrt{1 + \frac{1}{l}}$ is always larger than 1 (indicating that the period increases) but becomes smaller as l becomes larger.

- (d) The graphs of $T(2l)$, $T(3l)$, and $T(4l)$ are shown below:

- (e) Answers will vary, but one interpretation follows. Note that

$$T(2l) = 2\pi \sqrt{\frac{2l}{g}} = \sqrt{2} \cdot 2\pi \sqrt{\frac{l}{g}} = \sqrt{2} T(l).$$

Similarly, $T(3l) = \sqrt{3}T(l)$, and $T(4l) = \sqrt{4}T(l) = 2T(l)$. Thus, multiplying the length of the pendulum by 2, 3, and 4, multiplies the period of the pendulum by $\sqrt{2}$, $\sqrt{3}$, and $\sqrt{4} = 2$, respectively.

50. (a) The graph of $y = g(x + 3) - 5$ can be obtained from the graph of $y = g(x)$ by shifting horizontally left 3 units and vertically down 5 units. The graph of $y = g(x + 3) - 5$ therefore contains the point $(1 - 3, 3 - 5) = \boxed{(-2, -2)}$.
- (b) The graph of $y = -2g(x - 2) + 1$ can be obtained from the graph of $y = g(x)$ by shifting horizontally right 2 units, stretching vertically by a factor of 2, reflecting about the x -axis, and finally shifting vertically up 1 unit. The graph of $y = -2g(x - 2) + 1$ therefore contains the point $(1 + 2, -2 \cdot 3 + 1) = \boxed{(3, -5)}$.
- (c) The graph of $y = g(2x + 3)$ can be obtained from the graph of $y = g(x)$ by shifting horizontally left 3 units and then compressing horizontally by a factor of $\frac{1}{2}$. The graph of $y = g(2x + 3)$ therefore contains the point $\left(\frac{1}{2}(1 - 3), 3\right) = \boxed{(-1, 3)}$.

P.4: Inverse Functions

Concepts and Vocabulary

1. False. If every **horizontal** line intersects the graph of a function f at no more than one point, f is a one-to-one function.
2. If the domain of a one-to-one function f is $[4, \infty)$, the range of its inverse f^{-1} is $[4, \infty)$.
3. False. If f and g are inverse functions, the domain of f **does not need to be** the same as the domain of g . However, the domain of f will always be the same as the **range** of g .
4. True. If f and g are inverse functions, their graphs are symmetric with respect to the line $y = x$.
5. False. If f and g are inverse functions, then $(f \circ g)(x) = (g \circ f)(x) = x$; that is, $f(g(x)) = g(f(x)) = x$.
6. False. If a function f is one-to-one, then $f(f^{-1}(x)) = x$, where x is in the domain of f^{-1} .
7. First, examine the x -coordinates of the ordered pairs. If each value of x appears in one and only one ordered pair, then the collection of points represents a function $y = f(x)$; otherwise, the collection of points is not a function. If the collection of points does represent a function, next check the y -coordinates. If each value of y appears in one and only one ordered pair, then the function represented by the collection of points is one-to-one; otherwise, the collection of points represents a function that is not one-to-one.
8. Given the graph of the one-to-one function $y = f(x)$, the graph of the inverse function f^{-1} can be obtained by reflecting the graph of f about the line $y = x$.

Practice Problems

9. The graph of f passes the horizontal line test, so this function is one-to-one.
10. The graph of f passes the horizontal line test, so this function is one-to-one.
11. The graph of f does not pass the horizontal line test (for example, the horizontal line $y = 2$ intersects the graph of f in two points), so this function is not one-to-one.
12. The graph of f does not pass the horizontal line test (for example, the horizontal line $y = 2$ intersects the graph of f in two points), so this function is not one-to-one.
13. The graph of f passes the horizontal line test, so this function is one-to-one.
14. The graph of f does not pass the horizontal line test (the horizontal line $y = 2$ intersects the graph in infinitely many points), so this function is not one-to-one.
15. Let $f(x) = 3x + 4$ and $g(x) = \frac{1}{3}(x - 4)$. Then

$$f(g(x)) = f\left(\frac{1}{3}(x - 4)\right) = 3 \cdot \frac{1}{3}(x - 4) + 4 = x - 4 + 4 = x,$$

and

$$g(f(x)) = g(3x + 4) = \frac{1}{3}(3x + 4 - 4) = \frac{1}{3}(3x) = x,$$

so that f and g are inverses of each other.

16. Let $f(x) = x^3 - 8$ and $g(x) = \sqrt[3]{x+8}$. Then

$$f(g(x)) = f(\sqrt[3]{x+8}) = (\sqrt[3]{x+8})^3 - 8 = x + 8 - 8 = x,$$

and

$$g(f(x)) = g(x^3 - 8) = \sqrt[3]{x^3 - 8 + 8} = \sqrt[3]{x^3} = x,$$

so that f and g are inverses of each other.

17. Let $f(x) = g(x) = \frac{1}{x}$. Then

$$f(g(x)) = f\left(\frac{1}{x}\right) = \frac{1}{\frac{1}{x}} = x,$$

and

$$g(f(x)) = g\left(\frac{1}{x}\right) = \frac{1}{\frac{1}{x}} = x,$$

so that f and g are inverses of each other.

18. Let $f(x) = \frac{2x+3}{x+4}$ and $g(x) = \frac{4x-3}{2-x}$. Then

$$f(g(x)) = f\left(\frac{4x-3}{2-x}\right) = \frac{2\frac{4x-3}{2-x} + 3}{\frac{4x-3}{2-x} + 4} = \frac{2(4x-3) + 3(2-x)}{4x-3 + 4(2-x)} = \frac{8x-6+6-3x}{4x-3+8-4x} = \frac{5x}{5} = x,$$

and

$$g(f(x)) = g\left(\frac{2x+3}{x+4}\right) = \frac{4\frac{2x+3}{x+4} - 3}{2 - \frac{2x+3}{x+4}} = \frac{4(2x+3) - 3(x+4)}{2(x+4) - (2x+3)} = \frac{8x+12-3x-12}{2x+8-2x-3} = \frac{5x}{5} = x,$$

so that f and g are inverses of each other.

19. (a) Because each value of the second coordinate appears in one and only one ordered pair, this is a one-to-one function.
 (b) Because the function is one-to-one, the function has an inverse. To obtain the inverse, interchange the coordinates in each ordered pair; thus, the inverse f^{-1} is the set

$$\{(5, -3), (9, -2), (2, -1), (11, 0), (-5, 1)\}.$$

- (c) The domain of f is the set $\{-3, -2, -1, 0, 1\}$, and the range of f is the set $\{-5, 2, 5, 9, 11\}$. The domain of f^{-1} is the set $\{-5, 2, 5, 9, 11\}$, and the range of f^{-1} is the set $\{-3, -2, -1, 0, 1\}$.
20. (a) Because the number 8 appears as the second coordinate in two ordered pairs with different first coordinates, $(0, 8)$ and $(2, 8)$, this is not a one-to-one function.
 (b) Because the function is not one-to-one, the function does not have an inverse.
 (c) The domain of f is the set $\{-2, -1, 0, 1, 2\}$, and the range of f is the set $\{-3, 2, 6, 8\}$. There is no inverse function.
21. (a) Because the number 1 appears as the second coordinate in two ordered pairs with different first coordinates, $(-2, 1)$ and $(2, 1)$, this is not a one-to-one function.
 (b) Because the function is not one-to-one, the function does not have an inverse.
 (c) The domain of f is the set $\{-10, -3, -2, 1, 2\}$, and the range of f is the set $\{0, 1, 2, 9\}$. There is no inverse function.

22. (a) Because each value of the second coordinate appears in one and only one ordered pair, this is a one-to-one function.
- (b) Because the function is one-to-one, the function has an inverse. To obtain the inverse, interchange the coordinates in each ordered pair; thus, the inverse f^{-1} is the set

$$\{(-8, -2), (-1, -1), (0, 0), (1, 1), (8, 2)\}.$$

- (c) The domain of f is the set $\{-2, -1, 0, 1, 2\}$, and the range of f is the set $\{-8, -1, 0, 1, 8\}$. The domain of f^{-1} is the set $\{-8, -1, 0, 1, 8\}$, and the range of f^{-1} is the set $\{-2, -1, 0, 1, 2\}$.
23. In the figure below, the dashed curve is the graph of $y = f(x)$ and the solid curve is the graph of $y = f^{-1}(x)$. The graph of $y = x$ is included for clarity. Observe how the graph of $y = f^{-1}(x)$ is the reflection of the graph of $y = f(x)$ about the line $y = x$.

24. In the figure below, the dashed curve is the graph of $y = f(x)$ and the solid curve is the graph of $y = f^{-1}(x)$. The graph of $y = x$ is included for clarity. Observe how the graph of $y = f^{-1}(x)$ is the reflection of the graph of $y = f(x)$ about the line $y = x$.

25. In the figure below, the dashed curve is the graph of $y = f(x)$ and the solid curve is the graph of $y = f^{-1}(x)$. The graph of $y = x$ is included for clarity. Observe how the graph of $y = f^{-1}(x)$ is the reflection of the graph of $y = f(x)$ about the line $y = x$.

26. In the figure below, the dashed curve is the graph of $y = f(x)$ and the solid curve is the graph of $y = f^{-1}(x)$. The graph of $y = x$ is included for clarity. Observe how the graph of $y = f^{-1}(x)$ is the reflection of the graph of $y = f(x)$ about the line $y = x$.

27. In the figure below, the dashed curve is the graph of $y = f(x)$ and the solid curve is the graph of $y = f^{-1}(x)$. The graph of $y = x$ is included for clarity. Observe how the graph of $y = f^{-1}(x)$ is the reflection of the graph of $y = f(x)$ about the line $y = x$.

28. In the figure below, the dashed curve is the graph of $y = f(x)$ and the solid curve is the graph of $y = f^{-1}(x)$. The graph of $y = x$ is included for clarity. Observe how the graph of $y = f^{-1}(x)$ is the reflection of the graph of $y = f(x)$ about the line $y = x$.

29. (a) Start by writing $y = f(x) = 4x + 2$. Next, interchange the x and y variables to obtain an implicit definition of the inverse function: $x = 4y + 2$. To obtain the inverse function explicitly, solve the implicit equation for y :

$$4y = x - 2, \quad \text{so that} \quad y = \frac{1}{4}(x - 2).$$

Thus, $\boxed{f^{-1}(x) = \frac{1}{4}(x - 2)}$. To check that this is the correct formula for the inverse function, show that $f(f^{-1}(x)) = x$ and $f^{-1}(f(x)) = x$:

$$\begin{aligned} f(f^{-1}(x)) &= f\left(\frac{1}{4}(x - 2)\right) = 4\left(\frac{1}{4}(x - 2)\right) + 2 = x - 2 + 2 = \boxed{x}, \\ f^{-1}(f(x)) &= f^{-1}(4x + 2) = \frac{1}{4}(4x + 2 - 2) = \frac{1}{4}(4x) = \boxed{x}. \end{aligned}$$

- (b) Both the domain and range of f are the set of $\boxed{\text{all real numbers}}$ or the interval $\boxed{(-\infty, \infty)}$. The same is true for the inverse function. Both the domain and range of f^{-1} are the set of $\boxed{\text{all real numbers}}$ or the interval $\boxed{(-\infty, \infty)}$.
30. (a) Start by writing $y = f(x) = 1 - 3x$. Next, interchange the x and y variables to obtain an implicit definition of the inverse function: $x = 1 - 3y$. To obtain the inverse function explicitly, solve the implicit equation for y :

$$3y = 1 - x, \quad \text{so that} \quad y = \frac{1}{3}(1 - x).$$

Thus, $\boxed{f^{-1}(x) = \frac{1}{3}(1 - x)}$. To check that this is the correct formula for the inverse function, show that $f(f^{-1}(x)) = x$ and $f^{-1}(f(x)) = x$:

$$\begin{aligned} f(f^{-1}(x)) &= f\left(\frac{1}{3}(1 - x)\right) = 1 - 3\left(\frac{1}{3}(1 - x)\right) = 1 - (1 - x) = \boxed{x}, \\ f^{-1}(f(x)) &= f^{-1}(1 - 3x) = \frac{1}{3}(1 - (1 - 3x)) = \frac{1}{3}(3x) = \boxed{x}. \end{aligned}$$

- (b) Both the domain and range of f are the set of $\boxed{\text{all real numbers}}$ or the interval $\boxed{(-\infty, \infty)}$. The same is true for the inverse function. Both the domain and range of f^{-1} are the set of $\boxed{\text{all real numbers}}$ or the interval $\boxed{(-\infty, \infty)}$.
31. (a) Start by writing $y = f(x) = \sqrt[3]{x + 10}$. Next, interchange the x and y variables to obtain an implicit definition of the inverse function: $x = \sqrt[3]{y + 10}$. To obtain the inverse function explicitly, solve the implicit equation for y :

$$y + 10 = x^3, \quad \text{so that} \quad y = x^3 - 10.$$

Thus, $\boxed{f^{-1}(x) = x^3 - 10}$. To check that this is the correct formula for the inverse function, show that $f(f^{-1}(x)) = x$ and $f^{-1}(f(x)) = x$:

$$\begin{aligned} f(f^{-1}(x)) &= f(x^3 - 10) = \sqrt[3]{(x^3 - 10) + 10} = \sqrt[3]{x^3} = \boxed{x}, \\ f^{-1}(f(x)) &= f^{-1}(\sqrt[3]{x + 10}) = (\sqrt[3]{x + 10})^3 - 10 = x + 10 - 10 = \boxed{x}. \end{aligned}$$

- (b) Both the domain and range of f are the set of $\boxed{\text{all real numbers}}$ or the interval $\boxed{(-\infty, \infty)}$. The same is true for the inverse function. Both the domain and range of f^{-1} are the set of $\boxed{\text{all real numbers}}$ or the interval $\boxed{(-\infty, \infty)}$.

32. (a) Start by writing $y = f(x) = 2x^3 + 4$. Next, interchange the x and y variables to obtain an implicit definition of the inverse function: $x = 2y^3 + 4$. To obtain the inverse function explicitly, solve the implicit equation for y :

$$2y^3 = x - 4, \quad \text{so that} \quad y = \sqrt[3]{\frac{x - 4}{2}}.$$

Thus, $\boxed{f^{-1}(x) = \sqrt[3]{\frac{x - 4}{2}}}$. To check that this is the correct formula for the inverse function, show that $f(f^{-1}(x)) = x$ and $f^{-1}(f(x)) = x$:

$$\begin{aligned} f(f^{-1}(x)) &= f\left(\sqrt[3]{\frac{x - 4}{2}}\right) = 2\left(\sqrt[3]{\frac{x - 4}{2}}\right)^3 + 4 = 2\left(\frac{x - 4}{2}\right) + 4 = x - 4 + 4 = \boxed{x}, \\ f^{-1}(f(x)) &= f^{-1}(2x^3 + 4) = \sqrt[3]{\frac{2x^3 + 4 - 4}{2}} = \sqrt[3]{x^3} = \boxed{x}. \end{aligned}$$

- (b) Both the domain and range of f are the set of $\boxed{\text{all real numbers}}$ or the interval $\boxed{(-\infty, \infty)}$. The same is true for the inverse function. Both the domain and range of f^{-1} are the set of $\boxed{\text{all real numbers}}$ or the interval $\boxed{(-\infty, \infty)}$.

33. (a) Start by writing $y = f(x) = \frac{1}{x - 2}$. Next, interchange the x and y variables to obtain an implicit definition of the inverse function: $x = \frac{1}{y - 2}$. To obtain the inverse function explicitly, solve the implicit equation for y :

$$y - 2 = \frac{1}{x}, \quad \text{so that} \quad y = \frac{1}{x} + 2.$$

Thus, $\boxed{f^{-1}(x) = \frac{1}{x} + 2}$. To check that this is the correct formula for the inverse function, show that $f(f^{-1}(x)) = x$ and $f^{-1}(f(x)) = x$:

$$\begin{aligned} f(f^{-1}(x)) &= f\left(\frac{1}{x} + 2\right) = \frac{1}{\frac{1}{x} + 2 - 2} = \frac{1}{\frac{1}{x}} = \boxed{x}, \\ f^{-1}(f(x)) &= f^{-1}\left(\frac{1}{x - 2}\right) = \frac{1}{\frac{1}{x - 2}} + 2 = x - 2 + 2 = \boxed{x}. \end{aligned}$$

- (b) The domain of f is the set $\boxed{\{x|x \neq 2\}}$, and the range of f is the set $\boxed{\{y|y \neq 0\}}$. The domain of f^{-1} is the set $\boxed{\{x|x \neq 0\}}$, and the range of f^{-1} is the set $\boxed{\{y|y \neq 2\}}$.

34. (a) Start by writing $y = f(x) = \frac{2x}{3x-1}$. Next, interchange the x and y variables to obtain an implicit definition of the inverse function: $x = \frac{2y}{3y-1}$. To obtain the inverse function explicitly, solve the implicit equation for y :

$$\begin{aligned} x(3y-1) &= 2y \\ 3xy-x &= 2y \\ 3xy-2y &= x \\ y(3x-2) &= x \\ y &= \boxed{\frac{x}{3x-2} = f^{-1}(x)}. \end{aligned}$$

To check that this is the correct formula for the inverse function, show that $f(f^{-1}(x)) = x$ and $f^{-1}(f(x)) = x$:

$$\begin{aligned} f(f^{-1}(x)) &= f\left(\frac{x}{3x-2}\right) = \frac{2\frac{x}{3x-2}}{3\frac{x}{3x-2}-1} = \frac{2x}{3x-(3x-2)} = \frac{2x}{2} = \boxed{x}, \\ f^{-1}(f(x)) &= f^{-1}\left(\frac{2x}{3x-1}\right) = \frac{\frac{2x}{3x-1}}{3\frac{2x}{3x-1}-2} = \frac{2x}{6x-2(3x-1)} = \frac{2x}{2} = \boxed{x}. \end{aligned}$$

- (b) The domain of f is the set $\boxed{\{x|x \neq \frac{1}{3}\}}$, and the range of f is the set $\boxed{\{y|y \neq \frac{2}{3}\}}$. The domain of f^{-1} is the set $\boxed{\{x|x \neq \frac{2}{3}\}}$, and the range of f^{-1} is the set $\boxed{\{y|y \neq \frac{1}{3}\}}$.
35. (a) Start by writing $y = f(x) = \frac{2x+3}{x+2}$. Next, interchange the x and y variables to obtain an implicit definition of the inverse function: $x = \frac{2y+3}{y+2}$. To obtain the inverse function explicitly, solve the implicit equation for y :

$$\begin{aligned} x(y+2) &= 2y+3 \\ xy+2x &= 2y+3 \\ xy-2y &= 3-2x \\ y(x-2) &= 3-2x \\ y &= \boxed{\frac{3-2x}{x-2} = f^{-1}(x)}. \end{aligned}$$

To check that this is the correct formula for the inverse function, show that $f(f^{-1}(x)) = x$ and $f^{-1}(f(x)) = x$:

$$\begin{aligned} f(f^{-1}(x)) &= f\left(\frac{3-2x}{x-2}\right) = \frac{2\frac{3-2x}{x-2}+3}{\frac{3-2x}{x-2}+2} = \frac{2(3-2x)+3(x-2)}{3-2x+2(x-2)} = \frac{-x}{-1} = \boxed{x}, \\ f^{-1}(f(x)) &= f^{-1}\left(\frac{2x+3}{x+2}\right) = \frac{3-2\frac{2x+3}{x+2}}{\frac{2x+3}{x+2}-2} = \frac{3(x+2)-2(2x+3)}{2x+3-2(x+2)} = \frac{-x}{-1} = \boxed{x}. \end{aligned}$$

- (b) The domain of f is the set $\boxed{\{x|x \neq -2\}}$, and the range of f is the set $\boxed{\{y|y \neq 2\}}$. The domain of f^{-1} is the set $\boxed{\{x|x \neq 2\}}$, and the range of f^{-1} is the set $\boxed{\{y|y \neq -2\}}$.
36. (a) Start by writing $y = f(x) = \frac{-3x-4}{x-2}$. Next, interchange the x and y variables to obtain an implicit definition of the inverse function: $x = \frac{-3y-4}{y-2}$. To obtain the inverse function explicitly,

solve the implicit equation for y :

$$\begin{aligned}x(y-2) &= -3y-4 \\xy-2x &= -3y-4 \\xy+3y &= 2x-4 \\y(x+3) &= 2x-4 \\y &= \boxed{\frac{2x-4}{x+3} = f^{-1}(x)}.\end{aligned}$$

To check that this is the correct formula for the inverse function, show that $f(f^{-1}(x)) = x$ and $f^{-1}(f(x)) = x$:

$$\begin{aligned}f(f^{-1}(x)) &= f\left(\frac{2x-4}{x+3}\right) = \frac{-3\frac{2x-4}{x+3}-4}{\frac{2x-4}{x+3}-2} = \frac{-3(2x-4)-4(x+3)}{2x-4-2(x+3)} = \frac{-10x}{-10} = \boxed{x}, \\f^{-1}(f(x)) &= f^{-1}\left(\frac{-3x-4}{x-2}\right) = \frac{2\frac{-3x-4}{x-2}-4}{\frac{-3x-4}{x-2}+3} = \frac{2(-3x-4)-4(x-2)}{-3x-4+3(x-2)} = \frac{-10x}{-10} = \boxed{x}.\end{aligned}$$

- (b) The domain of f is the set $\boxed{\{x|x \neq 2\}}$, and the range of f is the set $\boxed{\{y|y \neq -3\}}$. The domain of f^{-1} is the set $\boxed{\{x|x \neq -3\}}$, and the range of f^{-1} is the set $\boxed{\{y|y \neq 2\}}$.
37. (a) Start by writing $y = f(x) = x^2 + 4$, where $x \geq 0$. Next interchange the x and y variables to obtain an implicit definition of the inverse function: $x = y^2 + 4$, where $y \geq 0$. To obtain the inverse function explicitly, solve the implicit equation for y :

$$y^2 = x - 4, \quad \text{so that} \quad y = \pm\sqrt{x-4}.$$

Because $y \geq 0$, only the positive square root is appropriate; thus, $\boxed{f^{-1}(x) = \sqrt{x-4}}$. To check that this is the correct formula for the inverse function, show that $f(f^{-1}(x)) = x$ and $f^{-1}(f(x)) = x$:

$$\begin{aligned}f(f^{-1}(x)) &= f(\sqrt{x-4}) = (\sqrt{x-4})^2 + 4 = x - 4 + 4 = \boxed{x}, \\f^{-1}(f(x)) &= f^{-1}(x^2 + 4) = \sqrt{x^2 + 4 - 4} = \sqrt{x^2} = |x| = \boxed{x},\end{aligned}$$

where, in both calculations, attention is restricted to $x \geq 0$.

- (b) The domain of f is the set $\boxed{\{x|x \geq 0\}}$, and the range of f is the set $\boxed{\{y|y \geq 4\}}$. The domain of f^{-1} is the set $\boxed{\{x|x \geq 4\}}$, and the range of f^{-1} is the set $\boxed{\{y|y \geq 0\}}$.
38. (a) Start by writing $y = f(x) = (x-2)^2 + 4$, where $x \leq 2$. Next interchange the x and y variables to obtain an implicit definition of the inverse function: $x = (y-2)^2 + 4$, where $y \leq 2$. To obtain the inverse function explicitly, solve the implicit equation for y :

$$(y-2)^2 = x - 4, \quad \text{so that} \quad y = 2 \pm \sqrt{x-4}.$$

Because $y \leq 2$, only the negative square root is appropriate; thus, $\boxed{f^{-1}(x) = 2 - \sqrt{x-4}}$. To check that this is the correct formula for the inverse function, show that $f(f^{-1}(x)) = x$ and $f^{-1}(f(x)) = x$:

$$\begin{aligned}f(f^{-1}(x)) &= f(2 - \sqrt{x-4}) = (2 - \sqrt{x-4} - 2)^2 + 4 \\&= (-\sqrt{x-4})^2 + 4 = x - 4 + 4 = \boxed{x}, \\f^{-1}(f(x)) &= f^{-1}((x-2)^2 + 4) = 2 - \sqrt{(x-2)^2 + 4 - 4} \\&= 2 - \sqrt{(x-2)^2} = 2 - |x-2| = 2 - (2-x) = \boxed{x},\end{aligned}$$

where, in both calculations, attention is restricted to $x \leq 2$.

- (b) The domain of f is the set $\{x|x \leq 2\}$, and the range of f is the set $\{y|y \geq 4\}$. The domain of f^{-1} is the set $\{x|x \geq 4\}$, and the range of f^{-1} is the set $\{y|y \leq 2\}$.

P.5: Exponential and Logarithmic Functions

Concepts and Vocabulary

- The graph of every exponential function $f(x) = a^x$, $a > 0$ and $a \neq 1$, passes through three points: $\left(-1, \frac{1}{a}\right)$, $(0, 1)$, and $(1, a)$.
- False**. The graph of the exponential function $f(x) = \left(\frac{3}{2}\right)^x$ is **increasing**, because the base $a = \frac{3}{2} > 1$.
- If $3^x = 3^4$, then $x = 4$.
- If $4^x = 8^2$, then $x = 3$.
- False**. The graphs of $y = 3^x$ and $y = \left(\frac{1}{3}\right)^x = 3^{-x}$ are symmetric with respect to the y -axis. The graphs of $y = 3^x$ and its inverse function $y = \log_3 x$ are symmetric with respect to the line $y = x$.
- False**. The range of the exponential function $f(x) = a^x$, $a > 0$ and $a \neq 1$, is the set of **positive** real numbers.
- The number e is defined as the base of the exponential function f whose tangent line to the graph of f at the point $(0, 1)$ has slope **1**.
- The domain of the logarithmic function $f(x) = \log_a x$ is the set $\{x|x > 0\}$.
- The graph of every logarithmic function $f(x) = \log_a x$, $a > 0$ and $a \neq 1$, passes through three points: $\left(\frac{1}{a}, -1\right)$, $(1, 0)$, and $(a, 1)$.
- The graph of $f(x) = \log_2 x$ is **(a) increasing**, because the base $a = 2 > 1$.
- False**. If $y = \log_a x$, then $x = a^y$.
- True**. The graph of $f(x) = \log_a x$, $a > 0$ and $a \neq 1$, has an x -intercept equal to 1 and no y -intercept.
- True**. $\ln e^x = x$ for all real numbers.
- $\ln e = 1$.
- The number e is defined as the base of the exponential function f whose tangent line to the graph of f at the point $(0, 1)$ has slope 1.
- The x -intercept of the function $f(x) = \ln x$ is 1. Because the graph of $h(x) = \ln(x+1)$ can be obtained from the graph of $f(x) = \ln x$ by shifting horizontally left 1 unit, the x -intercept of the function $h(x) = \ln(x+1)$ is $1 - 1 = 0$.

Practice Problems

- Let $g(x) = 4^x + 2$.
 - $g(-1) = 4^{-1} + 2 = \frac{1}{4} + 2 = \frac{9}{4}$. The corresponding point on the graph of g is $\left(-1, \frac{9}{4}\right)$.
 - If $g(x) = 4^x + 2 = 66$, then $4^x = 64 = 4^3$. It follows that $x = 3$. The corresponding point on the graph of g is $(3, 66)$.
- Let $g(x) = 5^x - 3$.
 - $g(-1) = 5^{-1} - 3 = \frac{1}{5} - 3 = -\frac{14}{5}$. The corresponding point on the graph of g is $\left(-1, -\frac{14}{5}\right)$.

- (b) If $g(x) = 5^x - 3 = 122$, then $5^x = 125 = 5^3$. It follows that $x = 3$. The corresponding point on the graph of g is $(3, 122)$.
19. The graph appears to be the reflection of $y = 3^x$ about the y -axis. The function would therefore be **(a):** $y = 3^{-x}$.
20. The graph appears to be $y = 3^x$ shifted horizontally right 1 unit. The function would therefore be **(e):** $y = 3^{x-1}$.
21. The graph appears to be the reflection of $y = 3^x$ about both the x -axis and the y -axis. The function would therefore be **(c):** $y = -3^{-x}$.
22. The graph appears to be the reflection of $y = 3^x$ about the x -axis and then shifted vertically up 1 unit. The function would therefore be **(f):** $y = 1 - 3^x$.
23. The graph appears to be the reflection of $y = 3^x$ about the x -axis. The function would therefore be **(b):** $y = -3^x$.
24. The graph appears to be $y = 3^x$ shifted vertically down 1 unit. The function would therefore be **(d):** $y = 3^x - 1$.
25. The graph of $y = 2^{x+2}$ can be obtained from the graph of $y = 2^x$ by shifting horizontally left 2 units. In the figure below, the dashed curve represents the graph of $y = 2^x$, and the solid curve represents the graph of $y = 2^{x+2}$. The domain of f is the set of all real numbers or the interval $(-\infty, \infty)$, and the range is the set $\{y|y > 0\}$ or the interval $(0, \infty)$.

26. The graph of $y = 1 - 2^{-x/3}$ can be obtained from the graph of $y = 2^x$ through the following sequence of transformations: reflect about the y -axis, stretch horizontally by a factor of 3, reflect about the x -axis, and shift vertically up 1 unit. In the figures below, the dashed curve represents the graph of $y = 2^x$, the dash-dot curve represents the graph of $y = 2^{-x}$, the dash-double dot curve represents the graph of $y = 2^{-x/3}$, the dotted curve represents the graph of $y = -2^{-x/3}$, and the solid curve represents the graph of $y = 1 - 2^{-x/3}$. The domain of f is the set of all real numbers or the interval $(-\infty, \infty)$, and the range is the set $\{y|y < 1\}$ or the interval $(-\infty, 1)$.

27. The graph of $y = 4\left(\frac{1}{3}\right)^x$ can be obtained from the graph of $y = \left(\frac{1}{3}\right)^x$ by stretching vertically by a factor of 4. In the figure below, the dashed curve represents the graph of $y = \left(\frac{1}{3}\right)^x$, and the solid curve represents the graph of $y = 4\left(\frac{1}{3}\right)^x$. The domain of f is the set of all real numbers or the interval $(-\infty, \infty)$, and the range is the set $\{y|y > 0\}$ or the interval $(0, \infty)$.

28. The graph of $f(x) = \left(\frac{1}{2}\right)^{-x} + 1$ can be obtained from the graph of $f(x) = \left(\frac{1}{2}\right)^{-x}$ by reflecting about the y -axis and then shifting vertically up 1 unit. In the figure below at the left, the graph of $f(x) = \left(\frac{1}{2}\right)^x$ is represented by the dashed curve, and the graph of $f(x) = \left(\frac{1}{2}\right)^{-x}$ is

represented by the dash-dot curve. In the figure below at the right, the graph of $f(x) = \left(\frac{1}{2}\right)^{-x}$ is represented by the dash-dot curve, and the graph of $f(x) = \left(\frac{1}{2}\right)^{-x} + 1$ is represented by the solid curve. The domain of f is the set of all real numbers or the interval $(-\infty, \infty)$, and the range is the set $\{y|y > 1\}$ or the interval $(1, \infty)$.

29. The graph of $y = e^{-x}$ can be obtained from the graph of $y = e^x$ by reflecting about the y -axiss. In the figure below, the dashed curve represents the graph of $y = e^x$, and the solid curve represents the graph of $y = e^{-x}$. The domain of f is the set of all real numbers or the interval $(-\infty, \infty)$, and the range is the set $\{y|y > 0\}$ or the interval $(0, \infty)$.

30. The graph of $y = 5 - e^x$ can be obtained from the graph of $y = e^x$ by reflecting about the x -axis and then shifting vertically up 5 units. In the figure below at the left, the graph of $y = e^x$ is represented by the dashed curve, and the graph of $y = -e^x$ is represented by the dash-dot curve. In the figure below at the right, the graph of $y = -e^x$ is represented by the dash-dot curve, and the graph of $y = 5 - e^x$ is represented by the solid curve. The domain of f is the set of all real numbers or the interval $(-\infty, \infty)$, and the range is the set $\{y|y < 5\}$ or the interval $(-\infty, 5)$.

31. The argument of a logarithmic function must be positive, so the domain of $F(x) = \log_2 x^2$ is the solution of the inequality $x^2 > 0$. The domain of F is therefore the set $\{x|x \neq 0\}$.
32. The argument of a logarithmic function must be positive, so the domain of $g(x) = 8 + 5 \ln(2x + 3)$ is the solution of the inequality $2x + 3 > 0$. The domain of g is therefore the set $\{x|x > -\frac{3}{2}\}$.
33. The argument of a logarithmic function must be positive, so the domain of $f(x) = \ln(x - 1)$ is the solution of the inequality $x - 1 > 0$. The domain of f is therefore the set $\{x|x > 1\}$.
34. The square root function is only defined for nonnegative real numbers, so the domain of $g(x) = \sqrt{\ln x}$ is the solution of the inequality $\ln x \geq 0$. Because $\ln 1 = 0$ and the natural logarithm function is increasing for all real numbers, it follows that the domain of g is the set $\{x|x \geq 1\}$.
35. The graph appears to be the reflection of $y = \log_3 x$ about the y -axis. The function would therefore be **(b)**: $y = \log_3(-x)$.
36. The graph appears to be $y = \log_3 x$ shifted horizontally right 1 unit. The function would therefore be **(e)**: $y = \log_3(x - 1)$.
37. The graph appears to be the reflection of $y = \log_3 x$ about the x -axis and then shifted vertically up 1 unit. The function would therefore be **(f)**: $y = 1 - \log_3 x$.
38. The graph appears to be $y = \log_3 x$. The function would therefore be **(a)**: $y = \log_3 x$.
39. The graph appears to be the reflection of $y = \log_3 x$ about the x -axis. The function would therefore be **(c)**: $y = -\log_3 x$.
40. The graph appears to be $y = \log_3 x$ shifted vertically down 1 unit. The function would therefore be **(d)**: $y = \log_3 x - 1$.
41. (a) The argument of a logarithmic function must be positive, so the domain of $f(x) = \ln(x + 4)$ is the solution of the inequality $x + 4 > 0$. The domain of f is therefore the set $\{x|x > -4\}$.
- (b) The graph of $f(x) = \ln(x + 4)$ is shown below:

- (c) From the graph of f , the range of f is the set of all real numbers or the interval $(-\infty, \infty)$.
- (d) Start by writing $y = f(x) = \ln(x + 4)$. Next, interchange the variables x and y to obtain $x = \ln(y + 4)$. Finally, solve for y :

$$y + 4 = e^x, \quad \text{so that} \quad y = \boxed{f^{-1}(x) = e^x - 4}.$$

- (e) Recall that the range of f is the domain of its inverse function f^{-1} . Because the domain of f^{-1} is the set of all real numbers, the range of f is the set of all real numbers or the interval $(-\infty, \infty)$.
- (f) The graph of $f^{-1}(x) = e^x - 4$ is shown below:

42. (a) The argument of a logarithmic function must be positive, so the domain of $f(x) = \frac{1}{2} \ln(2x)$ is the solution of the inequality $2x > 0$. The domain of f is therefore the set $\{x | x > 0\}$.
- (b) The graph of $f(x) = \frac{1}{2} \ln(2x)$ is shown below:

- (c) From the graph of f , the range of f is the set of all real numbers or the interval $(-\infty, \infty)$.
- (d) Start by writing $y = f(x) = \frac{1}{2} \ln(2x)$. Next, interchange the variables x and y to obtain $x = \frac{1}{2} \ln(2y)$. Finally, solve for y :

$$2y = e^{2x}, \quad \text{so that} \quad y = \boxed{f^{-1}(x) = \frac{1}{2}e^{2x}}.$$

- (e) Recall that the range of f is the domain of its inverse function f^{-1} . Because the domain of f^{-1} is the set of all real numbers, the range of f is the set of all real numbers or the interval $(-\infty, \infty)$.
- (f) The graph of $f^{-1}(x) = \frac{1}{2}e^{2x}$ is shown below:

43. (a) The domain of $f(x) = 3e^x + 2$ is the set of all real numbers or the interval $(-\infty, \infty)$.
- (b) The graph of $f(x) = 3e^x + 2$ is shown below:

- (c) From the graph of f , the range of f is the set $\{y|y > 2\}$.
- (d) Start by writing $y = f(x) = 3e^x + 2$. Next, interchange the variables x and y to obtain $x = 3e^y + 2$. Finally, solve for y :

$$e^y = \frac{1}{3}(x - 2), \quad \text{so that} \quad y = \boxed{f^{-1}(x) = \ln\left(\frac{x-2}{3}\right)}.$$

- (e) Recall that the range of f is the domain of its inverse function f^{-1} . Because the domain of f^{-1} is the set $\{x|x > 2\}$, the range of f is the set $\{y|y > 2\}$.
- (f) The graph of $f^{-1}(x) = \ln\left(\frac{x-2}{3}\right)$ is shown below:

44. (a) The domain of $f(x) = 2^{x/3} + 4$ is the set of all real numbers or the interval $(-\infty, \infty)$.
 (b) The graph of $f(x) = 2^{x/3} + 4$ is shown below:

- (c) From the graph of f , the range of f is the set $\{y|y > 4\}$.
 (d) Start by writing $y = f(x) = 2^{x/3} + 4$. Next, interchange the variables x and y to obtain $x = 2^{y/3} + 4$. Finally, solve for y :

$$2^{y/3} = x - 4, \quad \text{so that} \quad y = \boxed{f^{-1}(x) = 3 \log_2(x - 4)}.$$

- (e) Recall that the range of f is the domain of its inverse function f^{-1} . Because the domain of f^{-1} is the set $\{x|x > 4\}$, the range of f is the set $\{y|y > 4\}$.
 (f) The graph of $f^{-1}(x) = 3 \log_2(x - 4)$ is shown below:

45. The transformation $y = \ln(x + c)$, $c > 0$, shifts the graph of $f(x) = \ln x$ horizontally left by c units. This will move the x -intercept c units to the left.

46. The transformation $y = e^{cx}$, $c > 0$, horizontally stretches (if $0 < c < 1$) or compresses (if $c > 1$) the graph of $f(x) = e^x$. Because a horizontal transformation has no effect on the y -intercept of a graph, the y -intercept of $y = e^{cx}$ is the same as the y -intercept of $y = e^x$.

47. Because $9 = 3^2$, the equation can be written as

$$3^{x^2} = (3^2)^x = 3^{2x}.$$

By the one-to-one property of exponential functions, it follows that

$$x^2 = 2x, \quad \text{or} \quad x^2 - 2x = x(x - 2) = 0.$$

Thus, $x = 0$ or $x = 2$, and the solution set is $\{0, 2\}$.

48. Because $125 = 5^3$, the equation can be written as

$$5^{x^2+8} = (5^3)^{2x} = 5^{6x}.$$

By the one-to-one property of exponential functions, it follows that

$$x^2 + 8 = 6x, \quad \text{or} \quad x^2 - 6x + 8 = (x - 4)(x - 2) = 0.$$

Thus, $x = 4$ or $x = 2$, and the solution set is $\{2, 4\}$.

49. First, rewrite the equation as $e^{3x} = e^{2-x}$. Then, by the one-to-one property of exponential functions,

$$3x = 2 - x, \quad \text{or} \quad 4x = 2,$$

so that $x = \frac{1}{2}$.

50. First, rewrite the equation as $e^{4x+x^2} = e^{12}$. Then, by the one-to-one property of exponential functions,

$$4x + x^2 = 12, \quad \text{or} \quad x^2 + 4x - 12 = (x + 6)(x - 2) = 0.$$

Thus, $x = -6$ or $x = 2$, and the solution set is $\{-6, 2\}$.

51. The numbers e and 4 cannot be expressed with the same base, so apply the natural logarithm function to both sides of the equation. This yields

$$\begin{aligned} \ln(e^{1-2x}) &= \ln 4 \\ 1 - 2x &= \ln 4 \\ 2x &= 1 - \ln 4 \\ x &= \frac{1}{2}(1 - \ln 4). \end{aligned}$$

52. The numbers e and 5 cannot be expressed with the same base, so apply the natural logarithm function to both sides of the equation. This yields

$$\begin{aligned} \ln(e^{1-x}) &= \ln 5 \\ 1 - x &= \ln 5 \\ x &= 1 - \ln 5. \end{aligned}$$

53. First, rewrite the equation as $2^{3x} = \frac{9}{5}$, and then apply the natural logarithm function to both sides. This yields

$$\begin{aligned} \ln(2^{3x}) &= \ln\left(\frac{9}{5}\right) \\ 3x \ln 2 &= \ln\left(\frac{9}{5}\right) \\ x &= \frac{\ln(\frac{9}{5})}{3 \ln 2}. \end{aligned}$$

54. First, rewrite the equation as $4^{0.2x} = \frac{0.2}{0.3} = \frac{2}{3}$, and then apply the natural logarithm function to both sides. This yields

$$\begin{aligned}\ln(4^{0.2x}) &= \ln\left(\frac{2}{3}\right) \\ 0.2x \ln 4 &= \ln\left(\frac{2}{3}\right) \\ x &= \frac{\ln(\frac{2}{3})}{0.2 \ln 4} = \boxed{\frac{5 \ln(\frac{2}{3})}{\ln 4}}.\end{aligned}$$

55. Because the numbers 3 and 4 cannot be expressed with the same base, apply the natural logarithm function to both sides of the equation. This yields

$$\begin{aligned}\ln(3^{1-2x}) &= \ln(4^x) \\ (1-2x) \ln 3 &= x \ln 4 \\ \ln 3 - 2x \ln 3 &= x \ln 4 \\ -2x \ln 3 - x \ln 4 &= -\ln 3 \\ x(2 \ln 3 + \ln 4) &= \ln 3 \\ x &= \frac{\ln 3}{2 \ln 3 + \ln 4}.\end{aligned}$$

Using properties of logarithms, the answer can be simplified further as

$$x = \frac{\ln 3}{2 \ln 3 + \ln 4} = \frac{\ln 3}{\ln 3^2 + \ln 4} = \frac{\ln 3}{\ln(3^2 \cdot 4)} = \boxed{\frac{\ln 3}{\ln 36}}.$$

56. Because the numbers 2 and 5 cannot be expressed with the same base, apply the natural logarithm function to both sides of the equation. This yields

$$\begin{aligned}\ln(2^{x+1}) &= \ln(5^{1-2x}) \\ (x+1) \ln 2 &= (1-2x) \ln 5 \\ x \ln 2 + \ln 2 &= \ln 5 - 2x \ln 5 \\ x \ln 2 + 2x \ln 5 &= \ln 5 - \ln 2 \\ x(\ln 2 + 2 \ln 5) &= \ln 5 - \ln 2 \\ x &= \frac{\ln 5 - \ln 2}{\ln 2 + 2 \ln 5}.\end{aligned}$$

Using properties of logarithms, the answer can be simplified further as

$$x = \frac{\ln 5 - \ln 2}{\ln 2 + 2 \ln 5} = \frac{\ln(\frac{5}{2})}{\ln 2 + \ln 5^2} = \frac{\ln(\frac{5}{2})}{\ln(2 \cdot 5^2)} = \boxed{\frac{\ln(\frac{5}{2})}{\ln 50}}.$$

57. Change the logarithmic equation $\log_2(2x+1) = 3$ into the equivalent exponential equation $2x+1 = 2^3 = 8$. Then $2x = 7$, or $\boxed{x = \frac{7}{2}}$.

58. Change the logarithmic equation $\log_3(3x-2) = 2$ into the equivalent exponential equation $3x-2 = 3^2 = 9$. Then $3x = 11$, or $\boxed{x = \frac{11}{3}}$.

59. Change the logarithmic equation $\log_x\left(\frac{1}{8}\right) = 3$ into the equivalent exponential equation $x^3 = \frac{1}{8}$. Then

$$x = \sqrt[3]{\frac{1}{8}} = \boxed{\frac{1}{2}}.$$

60. Change the logarithmic equation $\log_x 64 = -3$ into the equivalent exponential equation $x^{-3} = 64$. Then

$$x^3 = \frac{1}{64}, \quad \text{or} \quad x = \sqrt[3]{\frac{1}{64}} = \boxed{\frac{1}{4}}.$$

61. Using the properties of logarithmic functions, $2 \ln 3 = \ln 3^2 = \ln 9$, so the equation can be written as $\ln(2x + 3) = \ln 9$. By the one-to-one property of logarithmic functions, it follows that $2x + 3 = 9$, so that $2x = 6$, or $\boxed{x = 3}$.
62. Using the properties of logarithmic functions, $\frac{1}{2} \log_3 x = \log_3 \sqrt{x}$ and $2 \log_3 2 = \log_3 2^2 = \log_3 4$, so the equation can be written as $\log_3 \sqrt{x} = \log_3 4$. By the one-to-one property of logarithmic functions, it follows that $\sqrt{x} = 4$, so that $\boxed{x = 16}$.
63. In the figure below at the left, the graph of $y = \log_5(x + 1) - \log_4(x - 2)$ is shown as the solid curve, and the graph of $y = 1$ is shown as the dashed curve. The two curves intersect once for x roughly between 2.5 and 3. Repeatedly zooming in until the x -coordinate of the point of intersection could be determined to three decimal places (see the figure below at the right), it follows that $x \approx 2.787$. Thus, to three decimal places the solution to the equation $\log_5(x + 1) - \log_4(x - 2) = 1$ is $\boxed{2.787}$.

64. In the figure below at the left, the graph of $y = \ln x$ is shown as the solid curve, and the graph of $y = x$ is shown as the dashed curve. As the two curves do not intersect, the equation $\ln x = x$ has $\boxed{\text{no solution}}$.

65. In the figure below at the left, the graph of $y = e^x + \ln x$ is shown as the solid curve, and the graph of $y = 4$ is shown as the dashed curve. The two curves intersect once for x roughly between 1.3 and 1.4. Repeatedly zooming in until the x -coordinate of the point of intersection could be determined to three

decimal places (see the figure below at the right), it follows that $x \approx 1.315$. Thus, to three decimal places the solution to the equation $e^x + \ln x = 4$ is $\boxed{1.315}$.

66. In the figure below at the left, the graph of $y = e^x$ is shown as the solid curve, and the graph of $y = x^2$ is shown as the dashed curve. The two curves intersect once for x between -0.8 and -0.6 . Repeatedly zooming in until the x -coordinate of the point of intersection could be determined to three decimal places (see the figure below at the right), it follows that $x \approx -0.703$. Thus, to three decimal places the solution to the equation $e^x = x^2$ is $\boxed{-0.703}$.

67. (a) The graphs of $f(x) = \ln(x + 4)$ and $g(x) = \ln(3x + 1)$ are shown in the figure below. The solid curve is the graph of f , and the dashed curve is the graph of g .

- (b) Form the equation $\ln(x + 4) = \ln(3x + 1)$. By the one-to-one property of the natural logarithm function, it follows that $x + 4 = 3x + 1$, so that $2x = 3$, or $x = \frac{3}{2}$. Thus, the graphs of

$f(x) = \ln(x + 4)$ and $g(x) = \ln(3x + 1)$ intersect in one point:

$$\left(\frac{3}{2}, \ln \frac{11}{2} \right).$$

This intersection point is marked and labeled in the figure above.

- (c) Based on the graph in part (a), the solution of the inequality $f(x) > g(x)$ is the set $\left\{ x \mid -\frac{1}{3} < x < \frac{3}{2} \right\}$.

The inequality $-\frac{1}{3} < x$ arises from the fact that the domain of the function g is $x > -\frac{1}{3}$.

68. (a) The graphs of $f(x) = 3^{x+1}$ and $g(x) = 2^{x+2}$ are shown in the figure below. The solid curve is the graph of f , and the dashed curve is the graph of g .

- (b) Form the equation $3^{x+1} = 2^{x+2}$. Because 2 and 3 cannot be expressed in terms of the same base, apply the natural logarithm function to both sides of the equation. This yields

$$\begin{aligned} \ln(3^{x+1}) &= \ln(2^{x+2}) \\ (x+1)\ln 3 &= (x+2)\ln 2 \\ x\ln 3 + \ln 3 &= x\ln 2 + 2\ln 2 \\ x(\ln 3 - \ln 2) &= 2\ln 2 - \ln 3 \\ x &= \frac{2\ln 2 - \ln 3}{\ln 3 - \ln 2} \approx 0.710. \end{aligned}$$

Thus, the graphs of $f(x) = 3^{x+1}$ and $g(x) = 2^{x+2}$ intersect in one point, given approximately by $(0.710, 6.541)$. This intersection point is marked and labeled in the figure above.

- (c) Based on the graph in part (a), the solution of the inequality $f(x) > g(x)$ is the set $\{x \mid x > 0.710\}$.

P.6: Trigonometric Functions

Concepts and Vocabulary

1. The sine, cosine, cosecant, and secant functions have period $\boxed{2\pi}$; the tangent and cotangent functions have period $\boxed{\pi}$.
2. The domain of the tangent function $f(x) = \tan x$ is $\boxed{\text{the set of all real numbers except odd multiples of } \frac{\pi}{2}}$.
3. The range of the sine function $f(x) = \sin x$ is $\boxed{\{y \mid -1 \leq y \leq 1\}}$.
4. The tangent function $f(x) = \tan x$ is periodic with period π . Therefore,

$$\tan \frac{\pi}{4} = \tan \left(\frac{\pi}{4} + \pi \right) = \tan \left(\frac{\pi}{4} + 2\pi \right).$$
5. $\boxed{\text{False}}$. The range of the secant function is the set $\{y \mid |y| \geq 1\}$, which is not all positive real numbers.
6. The function $f(x) = 3 \cos(6x)$ has amplitude $\boxed{3}$ and period $\frac{2\pi}{6} = \boxed{\frac{\pi}{3}}$.
7. $\boxed{\text{True}}$. The graphs of $y = \sin x$ and $y = \cos x$ are identical except for a horizontal shift. For example, the graph of $y = \cos x$ shifted horizontally right by $\frac{\pi}{2}$ units coincides with the graph of $y = \sin x$.
8. $\boxed{\text{False}}$. The amplitude of the function $f(x) = 2 \sin(\pi x)$ is 2 but its period is $\frac{2\pi}{\pi} = 2$.
9. $\boxed{\text{True}}$. The graph of the sine function has infinitely many x -intercepts. In particular, any x of the form $n\pi$ where n is an integer is an x -intercept of the sine function.
10. The graph of $y = \tan x$ is symmetric with respect to the $\boxed{\text{origin}}$.
11. The graph of $y = \sec x$ is symmetric with respect to the $\boxed{y\text{-axis}}$.
12. Answers will vary. One possibility is that a function is periodic if its values repeat over intervals of equal length.

Practice Problems

13. $\tan \left(-\frac{\pi}{4} \right) = -\tan \frac{\pi}{4} = \boxed{-1}$.
14. $\sin \left(-\frac{3\pi}{2} \right) = -\sin \frac{3\pi}{2} = -(-1) = \boxed{1}$.
15. $\csc \left(-\frac{\pi}{3} \right) = -\csc \frac{\pi}{3} = -\frac{2}{\sqrt{3}} = \boxed{-\frac{2\sqrt{3}}{3}}$.
16. $\cos \left(-\frac{\pi}{6} \right) = \cos \frac{\pi}{6} = \boxed{\frac{\sqrt{3}}{2}}$.
17. Because $f(0) = \tan 0 = 0$, the y -intercept of the tangent function is $\boxed{0}$.
18. In general, the x -intercepts of the function $f(x) = \sin x$ are the x values of the form $n\pi$ where n is an integer. Thus, the x -intercepts of the function $f(x) = \sin x$ on the closed interval $[-2\pi, 2\pi]$ are $\boxed{-2\pi, -\pi, 0, \pi, \text{ and } 2\pi}$.

19. The smallest value of the function $f(x) = \cos x$ is $\boxed{-1}$.

20. For $-2\pi \leq x \leq 2\pi$, $\sin x = 1$ when $\boxed{x = -\frac{3\pi}{2} \text{ and when } x = \frac{\pi}{2}}$. On the same interval, $\sin x = -1$ when $\boxed{x = -\frac{\pi}{2} \text{ and when } x = \frac{3\pi}{2}}$.

21. The graph appears to be a sine function, reflected about the x -axis, with an amplitude of 2 and a period of 4π . It follows that

$$A = -2 \quad \text{and} \quad \omega = \frac{2\pi}{4\pi} = \frac{1}{2}.$$

Thus, the function is $\boxed{\text{(f): } y = -2 \sin\left(\frac{1}{2}x\right)}$.

22. The graph appears to be a cosine function with an amplitude of 2 and a period of 4. It follows that

$$A = 2 \quad \text{and} \quad \omega = \frac{2\pi}{4} = \frac{\pi}{2}.$$

Thus, the function is $\boxed{\text{(b): } y = 2 \cos\left(\frac{\pi}{2}x\right)}$.

23. The graph appears to be a sine function with an amplitude of 2 and a period of 4. It follows that

$$A = 2 \quad \text{and} \quad \omega = \frac{2\pi}{4} = \frac{\pi}{2}.$$

Thus, the function is $\boxed{\text{(a): } y = 2 \sin\left(\frac{\pi}{2}x\right)}$.

24. The graph appears to be a cosine function, reflected about the x -axis, with an amplitude of 2 and a period of 4. It follows that

$$A = -2 \quad \text{and} \quad \omega = \frac{2\pi}{4} = \frac{\pi}{2}.$$

Thus, the function is $\boxed{\text{(e): } y = -2 \cos\left(\frac{\pi}{2}x\right)}$.

25. The graph appears to be a sine function, reflected about the x -axis, with an amplitude of 3 and a period of π . It follows that

$$A = -3 \quad \text{and} \quad \omega = \frac{2\pi}{\pi} = 2.$$

Thus, the function is $\boxed{\text{(d): } y = -3 \sin(2x)}$.

26. The graph appears to be a cosine function with an amplitude of 3 and a period of π . It follows that

$$A = 3 \quad \text{and} \quad \omega = \frac{2\pi}{\pi} = 2.$$

Thus, the function is $\boxed{\text{(c): } y = 3 \cos(2x)}$.

27. The graph of $f(x) = 4 \sin(\pi x)$ can be obtained from the graph of $y = \sin x$ by $\boxed{\text{compressing horizontally by a factor of } \frac{1}{\pi} \text{ and stretching vertically by a factor of } 4}$. The resulting amplitude will be 4, and the resulting period will be $\frac{2\pi}{\pi} = 2$. The graphs of $y = \sin x$, $y = \sin(\pi x)$, and $y = 4 \sin(\pi x)$ are shown below top left, below top right, and below bottom, respectively.

28. The graph of $f(x) = -3\cos x$ can be obtained from the graph of $y = \cos x$ by stretching vertically by a factor of 3 and then reflecting about the x -axis. The resulting amplitude will be $|-3| = 3$. The graphs of $y = \cos x$, $y = 3\cos x$, and $y = -3\cos x$ are shown below top left, below top right, and below bottom, respectively.

29. The graph of $f(x) = 3\cos(2x) - 4$ can be obtained from the graph of $y = \cos x$ by compressing horizontally by a factor of $\frac{1}{2}$, stretching vertically by a factor of 3, and then shifting vertically down 4 units. The resulting amplitude will be 3, and the resulting period will be $\frac{2\pi}{2} = \pi$. The graphs of $y = \cos x$, $y = \cos(2x)$, $y = 3\cos(2x)$, and $y = 3\cos(2x) - 4$ are shown below top left, below top right, below bottom left, and below bottom right, respectively.

30. The graph of $f(x) = 4\sin(2x) + 2$ can be obtained from the graph of $y = \sin x$ by compressing horizontally by a factor of $\frac{1}{2}$, stretching vertically by a factor of 4, and then shifting vertically up 2 units. The resulting amplitude will be 4, and the resulting period will be $\frac{2\pi}{2} = \pi$. The graphs of $y = \sin x$, $y = \sin(2x)$, $y = 4\sin(2x)$, and $y = 4\sin(2x) + 2$ are shown below top left, below top right, below bottom left, and below bottom right, respectively.

31. The graph of $f(x) = \tan\left(\frac{\pi}{2}x\right)$ can be obtained from the graph of $y = \tan x$ by compressing horizontally by a factor of $\frac{2}{\pi}$. The resulting period will be $\frac{\pi}{\pi/2} = 2$. The graphs of $y = \tan x$ and $y = \tan\left(\frac{\pi}{2}x\right)$ are shown below left and below right, respectively.

32. The graph of $f(x) = 4\sec\left(\frac{1}{2}x\right)$ can be obtained from the graph of $y = \sec x$ by stretching horizontally by a factor of 2 and stretching vertically by a factor of 4. The resulting period is $\frac{2\pi}{1/2} = 4\pi$. The graphs of $y = \sec x$, $y = \sec\left(\frac{1}{2}x\right)$, and $y = 4\sec\left(\frac{1}{2}x\right)$ are shown below top left, below top right, and below bottom, respectively.

33. Matching the function $g(x) = \frac{1}{2} \cos(\pi x)$ to the standard form $A \cos(\omega x)$, it follows that $A = \frac{1}{2}$ and $\omega = \pi$. Thus, the amplitude of the function g is $|A| = \frac{1}{2}$, and the period is

$$\frac{2\pi}{\omega} = \frac{2\pi}{\pi} = 2.$$

34. Matching the function $f(x) = \sin(2x)$ to the standard form $A \sin(\omega x)$, it follows that $A = 1$ and $\omega = 2$. Thus, the amplitude of the function f is $|A| = 1$, and the period is

$$\frac{2\pi}{\omega} = \frac{2\pi}{2} = \pi.$$

35. Matching the function $g(x) = 3 \sin x$ to the standard form $A \sin(\omega x)$, it follows that $A = 3$ and $\omega = 1$. Thus, the amplitude of the function g is $|A| = 3$, and the period is

$$\frac{2\pi}{\omega} = \frac{2\pi}{1} = 2\pi.$$

36. Matching the function $f(x) = -2 \cos\left(\frac{3}{2}x\right)$ to the standard form $A \cos(\omega x)$, it follows that $A = -2$ and $\omega = \frac{3}{2}$. Thus, the amplitude of the function f is $|A| = 2$, and the period is

$$\frac{2\pi}{\omega} = \frac{2\pi}{\frac{3}{2}} = \frac{4\pi}{3}.$$

37. With an amplitude of 2 and a period of π , $A = 2$,

$$\omega = \frac{2\pi}{\pi} = 2,$$

and the function is $f(x) = 2 \sin(2x)$.

38. With an amplitude of $\frac{1}{3}$ and a period of 2, $A = \frac{1}{3}$,

$$\omega = \frac{2\pi}{2} = \pi,$$

and the function is $f(x) = \frac{1}{3} \sin(\pi x)$.

39. With an amplitude of $\frac{1}{2}$ and a period of π , $A = \frac{1}{2}$,

$$\omega = \frac{2\pi}{\pi} = 2,$$

and the function is $f(x) = \frac{1}{2} \cos(2x)$.

40. With an amplitude of 3 and a period of 4π , $A = 3$,

$$\omega = \frac{2\pi}{4\pi} = \frac{1}{2},$$

and the function is $\boxed{f(x) = 3 \cos\left(\frac{1}{2}x\right)}$.

41. The graph appears to be a sine function with an amplitude of 1 and a period of $\frac{4\pi}{3}$ that has been reflected about the x -axis. Thus, $A = -1$,

$$\omega = \frac{2\pi}{\frac{4\pi}{3}} = \frac{3}{2},$$

and $\boxed{f(x) = -\sin\left(\frac{3}{2}x\right)}$.

42. The graph appears to be a cosine function with an amplitude of π and a period of 2π that has been reflected about the x -axis. Thus, $A = -\pi$,

$$\omega = \frac{2\pi}{2\pi} = 1,$$

and $\boxed{f(x) = -\pi \cos x}$.

43. The graph appears to be a cosine function with an amplitude of 1 and a period of $\frac{3}{2}$ that has been reflected about the x -axis and shifted vertically up 1 unit. Thus, $A = -1$,

$$\omega = \frac{2\pi}{\frac{3}{2}} = \frac{4\pi}{3},$$

and $\boxed{f(x) = 1 - \cos\left(\frac{4\pi}{3}x\right)}$.

44. The graph appears to be a sine function with an amplitude of $\frac{1}{2}$ and a period of $\frac{4\pi}{3}$ that has been reflected about the x -axis and shifted vertically down 1 unit. Thus, $A = -\frac{1}{2}$,

$$\omega = \frac{2\pi}{\frac{4\pi}{3}} = \frac{3}{2},$$

and $\boxed{f(x) = -1 - \frac{1}{2} \sin\left(\frac{3}{2}x\right)}$.

45. The graph appears to be just $\boxed{f(x) = \cot x}$.

46. The graph appears to be just $\boxed{f(x) = \tan x}$.

47. The graph appears to be a tangent function that has been shifted horizontally right $\frac{\pi}{2}$ units. Thus,

$$\boxed{f(x) = \tan\left(x - \frac{\pi}{2}\right)}.$$

48. The graph appears to be a cotangent function that has been shifted horizontally right $\frac{\pi}{2}$ units. Thus,

$$\boxed{f(x) = \cot\left(x - \frac{\pi}{2}\right)}.$$

P.7: Inverse Trigonometric Functions

Concepts and Vocabulary

1. $y = \sin^{-1} x$ if and only if $\boxed{x = \sin y}$, where $-1 \leq x \leq 1$ and $-\frac{\pi}{2} \leq y \leq \frac{\pi}{2}$.
2. $\boxed{\text{False}}$. $\sin^{-1}(\sin x) = x$, where $-\frac{\pi}{2} \leq x \leq \frac{\pi}{2}$. $\sin(\sin^{-1} x) = x$, where $-1 \leq x \leq 1$.
3. $\boxed{\text{False}}$. The domain of $f^{-1}(x) = \sin^{-1} x$ is $-1 \leq x \leq 1$. The range of the inverse sine function is $-\frac{\pi}{2} \leq y \leq \frac{\pi}{2}$.
4. $\boxed{\text{True}}$. $\sin(\sin^{-1} 0) = \sin 0 = 0$.
5. $\boxed{\text{False}}$. $f^{-1}(x) = \tan^{-1} x$ means $x = \tan y$, where $-\infty < x < \infty$ and $-\frac{\pi}{2} < y < \frac{\pi}{2}$.
6. $\boxed{\text{True}}$. The domain of the inverse tangent function is the set of all real numbers.
7. $\boxed{\text{True}}$. $\sec^{-1} 0.5$ is not defined. The domain of the inverse secant function is the set $\{x \mid |x| \geq 1\}$.
8. $\boxed{\text{True}}$. Trigonometric equations can have multiple solutions.

Practice Problems

9. The angle from the closed interval $\left[-\frac{\pi}{2}, \frac{\pi}{2}\right]$ whose sine is $\frac{\sqrt{2}}{2}$ is $\frac{\pi}{4}$. Thus, $\sin^{-1}\left(\frac{\sqrt{2}}{2}\right) = \boxed{\frac{\pi}{4}}$.
10. The angle from the closed interval $\left[-\frac{\pi}{2}, \frac{\pi}{2}\right]$ whose sine is $-\frac{1}{2}$ is $-\frac{\pi}{6}$. Thus, $\sin^{-1}\left(-\frac{1}{2}\right) = \boxed{-\frac{\pi}{6}}$.
11. The angle from $\left[0, \frac{\pi}{2}\right) \cup \left[\pi, \frac{3\pi}{2}\right)$ whose secant is 2 is $\frac{\pi}{3}$. Thus, $\sec^{-1}(2) = \boxed{\frac{\pi}{3}}$.
12. The angle from the open interval $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$ whose tangent is $\sqrt{3}$ is $\frac{\pi}{3}$. Thus, $\tan^{-1}(\sqrt{3}) = \boxed{\frac{\pi}{3}}$.
13. The angle from the open interval $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$ whose tangent is -1 is $-\frac{\pi}{4}$. Thus, $\tan^{-1}(-1) = \boxed{-\frac{\pi}{4}}$.
14. The angle from $\left[0, \frac{\pi}{2}\right) \cup \left[\pi, \frac{3\pi}{2}\right)$ whose secant is $\frac{2\sqrt{3}}{3}$ is $\frac{\pi}{3}$. Thus, $\sec^{-1}\left(\frac{2\sqrt{3}}{3}\right) = \boxed{\frac{\pi}{3}}$.
15. Because $\frac{\pi}{4}$ is in the open interval $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$, $\tan^{-1}\left(\tan \frac{\pi}{4}\right) = \boxed{\frac{\pi}{4}}$.
16. The angle from the open interval $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$ whose tangent is 0 is 0. Thus, $\tan^{-1}(\sin 0) = \tan^{-1} 0 = \boxed{0}$.
17. $\sin\left(\sin^{-1} \frac{3}{5}\right) = \boxed{\frac{3}{5}}$.
18. Let $\theta = \sec^{-1}(-3)$. The problem then becomes: evaluate $\tan \theta$, where $\pi \leq \theta < \frac{3\pi}{2}$ and $\sec \theta = -3$. From the identity $1 + \tan^2 x = \sec^2 x$, it follows that $\tan x = \pm\sqrt{\sec^2 x - 1}$. Because θ is a third quadrant angle and the tangent function is positive for all third quadrant angles,

$$\tan[\sec^{-1}(-3)] = \tan \theta = \sqrt{\sec^2 \theta - 1} = \sqrt{(-3)^2 - 1} = \sqrt{8} = \boxed{2\sqrt{2}}.$$

19. Because $\frac{4\pi}{5}$ is not in the range of the inverse sine function, an angle between $-\frac{\pi}{2}$ and $\frac{\pi}{2}$ must be found for which the sine function has the same value as $\sin \frac{4\pi}{5}$. Using the identity $\sin x = \sin(\pi - x)$, it follows that

$$\sin \frac{4\pi}{5} = \sin \left(\pi - \frac{4\pi}{5} \right) = \sin \frac{\pi}{5},$$

so

$$\sin^{-1} \left(\sin \frac{4\pi}{5} \right) = \sin^{-1} \left(\sin \frac{\pi}{5} \right) = \boxed{\frac{\pi}{5}}.$$

20. $\sec(\sec^{-1} 3) = \boxed{3}$.

21. Let $\theta = \sin^{-1} u$. The problem then becomes: evaluate $\cos \theta$ in term of u , where $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$ and $\sin \theta = u$. From the identity $\sin^2 x + \cos^2 x = 1$, it follows that $\cos x = \pm \sqrt{1 - \sin^2 x}$. Because θ is a first or fourth quadrant angle and the cosine function is positive for first and fourth quadrant angles,

$$\cos(\sin^{-1} u) = \cos \theta = \sqrt{1 - \sin^2 \theta} = \boxed{\sqrt{1 - u^2}}.$$

22. First, note that

$$\tan(\sin^{-1} u) = \frac{\sin(\sin^{-1} u)}{\cos(\sin^{-1} u)}.$$

Now, $\sin(\sin^{-1} u) = u$, and $\cos(\sin^{-1} u) = \sqrt{1 - u^2}$ by Problem 21, so

$$\tan(\sin^{-1} u) = \boxed{\frac{u}{\sqrt{1 - u^2}}}.$$

23. Let $\theta = \tan^{-1} u$. The problem then becomes: evaluate $\sec \theta$ in term of u , where $-\frac{\pi}{2} < \theta < \frac{\pi}{2}$ and $\tan \theta = u$. From the identity $1 + \tan^2 x = \sec^2 x$, it follows that $\sec x = \pm \sqrt{1 + \tan^2 x}$. Because θ is a first or fourth quadrant angle and the secant function is positive for first and fourth quadrant angles,

$$\sec(\tan^{-1} u) = \sec \theta = \sqrt{1 + \tan^2 \theta} = \boxed{\sqrt{1 + u^2}}.$$

24. Let x be in the closed interval $[-1, 1]$; that is, in the domain of the inverse sine function. It follows that $-x$ is also in the domain of the inverse sine function. Now, suppose that $\sin^{-1} x = \theta$ for some angle θ in the closed interval $[-\frac{\pi}{2}, \frac{\pi}{2}]$. Then $x = \sin \theta$. Multiplying both sides of this equation by -1 and using the fact that the sine function is odd yields

$$-x = -\sin \theta = \sin(-\theta).$$

Because $-\theta$ is also an angle in the closed interval $[-\frac{\pi}{2}, \frac{\pi}{2}]$,

$$\sin^{-1}(-x) = -\theta = -\sin^{-1} x,$$

and the inverse sine function is odd.

25. Let x be any real number; that is, in the domain of the inverse tangent function. It follows that $-x$ is also in the domain of the inverse tangent function. Now, suppose that $\tan^{-1} x = \theta$ for some angle θ in the open interval $(-\frac{\pi}{2}, \frac{\pi}{2})$. Then $x = \tan \theta$. Multiplying both sides of this equation by -1 and using the fact that the tangent function is odd yields

$$-x = -\tan \theta = \tan(-\theta).$$

Because $-\theta$ is also an angle in the open interval $(-\frac{\pi}{2}, \frac{\pi}{2})$,

$$\tan^{-1}(-x) = -\theta = -\tan^{-1} x,$$

and the inverse tangent function is odd.

26. Let $x = \sin^{-1} \frac{1}{2} = \frac{\pi}{6}$. Then

$$\begin{aligned}\cos x &= \cos \frac{\pi}{6} = \boxed{\frac{\sqrt{3}}{2}}, \\ \tan x &= \tan \frac{\pi}{6} = \boxed{\frac{\sqrt{3}}{3}}, \\ \cot x &= \cot \frac{\pi}{6} = \boxed{\sqrt{3}}, \\ \sec x &= \sec \frac{\pi}{6} = \boxed{\frac{2\sqrt{3}}{3}}, \\ \csc x &= \csc \frac{\pi}{6} = \boxed{2}.\end{aligned}$$

27. The angles whose tangent is $-\frac{\sqrt{3}}{3}$ are of the form $-\frac{\pi}{6} + k\pi$, where k is any integer. Among these, the ones that are in the interval $[0, 2\pi)$ are $\frac{5\pi}{6}$ and $\frac{11\pi}{6}$. The solution set is therefore $\boxed{\left\{\frac{5\pi}{6}, \frac{11\pi}{6}\right\}}$.

28. The angles whose secant is -2 are of the form $\frac{2\pi}{3} + 2k\pi$ and $\frac{4\pi}{3} + 2k\pi$, where k is any integer. Thus

$$\frac{3\theta}{2} = \frac{2\pi}{3} + 2k\pi \quad \text{or} \quad \frac{3\theta}{2} = \frac{4\pi}{3} + 2k\pi,$$

so that

$$\theta = \frac{4\pi}{9} + \frac{4k\pi}{3} \quad \text{or} \quad \theta = \frac{8\pi}{9} + \frac{4k\pi}{3}.$$

Among these, the ones that are in the interval $[0, 2\pi)$ are $\frac{4\pi}{9}$, $\frac{8\pi}{9}$, and $\frac{16\pi}{9}$. The solution set is therefore $\boxed{\left\{\frac{4\pi}{9}, \frac{8\pi}{9}, \frac{16\pi}{9}\right\}}$.

29. Solving the given equation for $\sin \theta$ yields $\sin \theta = -\frac{1}{2}$. The angles whose sine is $-\frac{1}{2}$ are of the form $-\frac{\pi}{6} + 2k\pi$ and $-\frac{5\pi}{6} + 2k\pi$, where k is any integer. Among these, the ones that are in the interval $[0, 2\pi)$ are $\frac{7\pi}{6}$ and $\frac{11\pi}{6}$. The solution set is therefore $\boxed{\left\{\frac{7\pi}{6}, \frac{11\pi}{6}\right\}}$.

30. Solving the given equation for $\cos \theta$ yields $\cos \theta = \frac{1}{2}$. The angles whose cosine is $\frac{1}{2}$ are of the form $\pm\frac{\pi}{3} + 2k\pi$, where k is any integer. Among these, the ones that are in the interval $[0, 2\pi)$ are $\frac{\pi}{3}$ and $\frac{5\pi}{3}$. The solution set is therefore $\boxed{\left\{\frac{\pi}{3}, \frac{5\pi}{3}\right\}}$.

31. The angles whose sine is -1 are of the form $\frac{3\pi}{2} + 2k\pi$, where k is any integer. Thus,

$$3\theta = \frac{3\pi}{2} + 2k\pi, \quad \text{so that} \quad \theta = \frac{\pi}{2} + \frac{2k\pi}{3}.$$

Among these, the ones that are in the interval $[0, 2\pi)$ are $\frac{\pi}{2}$, $\frac{7\pi}{6}$, and $\frac{11\pi}{6}$. The solution set is therefore

$$\boxed{\left\{\frac{\pi}{2}, \frac{7\pi}{6}, \frac{11\pi}{6}\right\}}.$$

32. The angles whose cosine is $\frac{1}{2}$ are of the form $\pm\frac{\pi}{3} + 2k\pi$, where k is any integer. Thus,

$$2\theta = \pm\frac{\pi}{3} + 2k\pi, \quad \text{so that} \quad \theta = \pm\frac{\pi}{6} + k\pi.$$

Among these, the ones that are in the interval $[0, 2\pi)$ are $\frac{\pi}{6}$, $\frac{5\pi}{6}$, $\frac{7\pi}{6}$, and $\frac{11\pi}{6}$. The solution set is

therefore $\boxed{\left\{\frac{\pi}{6}, \frac{5\pi}{6}, \frac{7\pi}{6}, \frac{11\pi}{6}\right\}}.$

33. Solving the given equation for $\cos \theta$ yields

$$\cos \theta = \pm\frac{1}{2}.$$

The angles that satisfy this equation are of the form $\pm\frac{\pi}{3} + 2k\pi$ and $\pm\frac{2\pi}{3} + 2k\pi$, where k is any integer.

Among these, the ones that are in the interval $[0, 2\pi)$ are $\frac{\pi}{3}$, $\frac{2\pi}{3}$, $\frac{4\pi}{3}$, and $\frac{5\pi}{3}$. The solution set is

therefore $\boxed{\left\{\frac{\pi}{3}, \frac{2\pi}{3}, \frac{4\pi}{3}, \frac{5\pi}{3}\right\}}.$

34. Solving the given equation for $\sin \theta$ yields

$$\sin \theta = \pm\frac{\sqrt{2}}{2}.$$

The angles that satisfy this equation are of the form $\frac{\pi}{4} + \frac{k\pi}{2}$, where k is any integer. Among these, the ones that are in the interval $[0, 2\pi)$ are $\frac{\pi}{4}$, $\frac{3\pi}{4}$, $\frac{5\pi}{4}$, and $\frac{7\pi}{4}$. The solution set is there-

fore $\boxed{\left\{\frac{\pi}{4}, \frac{3\pi}{4}, \frac{5\pi}{4}, \frac{7\pi}{4}\right\}}.$

35. Factor the given equation as

$$(2\sin \theta - 3)(\sin \theta - 1) = 0.$$

Then either $\sin \theta = \frac{3}{2}$ or $\sin \theta = 1$. The former equation has no solution, while the angles that satisfy the latter equation are of the form $\frac{\pi}{2} + 2k\pi$, where k is any integer. Among these, the only value that

is in the interval $[0, 2\pi)$ is $\frac{\pi}{2}$. The solution set is therefore $\boxed{\left\{\frac{\pi}{2}\right\}}.$

36. Factor the given equation as

$$(2\cos \theta + 1)(\cos \theta - 4) = 0.$$

Then either $\cos \theta = -\frac{1}{2}$ or $\cos \theta = 4$. The latter equation has no solution, while the angles that satisfy the former equation are of the form $\pm\frac{2\pi}{3} + 2k\pi$, where k is any integer. Among these, the ones that

are in the interval $[0, 2\pi)$ are $\frac{2\pi}{3}$ and $\frac{4\pi}{3}$. The solution set is therefore $\boxed{\left\{\frac{2\pi}{3}, \frac{4\pi}{3}\right\}}.$

37. Use the identity $\sin^2 \theta + \cos^2 \theta = 1$ to write $\cos^2 \theta = 1 - \sin^2 \theta$. The original equation then becomes

$$1 + \sin \theta = 2 - 2\sin^2 \theta, \quad \text{or} \quad 2\sin^2 \theta + \sin \theta - 1 = 0.$$

Factoring the left-hand side yields

$$(2\sin \theta - 1)(\sin \theta + 1) = 0,$$

so that either $\sin \theta = \frac{1}{2}$ or $\sin \theta = -1$. The angles that satisfy the former equation are of the form $\frac{\pi}{6} + 2k\pi$ and $\frac{5\pi}{6} + 2k\pi$, while the angles that satisfy the latter equation are of the form $\frac{3\pi}{2} + 2k\pi$, where k is any integer. Among all of these angles, the ones that are in the interval $[0, 2\pi)$ are $\frac{\pi}{6}$, $\frac{5\pi}{6}$, and $\frac{3\pi}{2}$. The solution set is therefore $\boxed{\left\{ \frac{\pi}{6}, \frac{5\pi}{6}, \frac{3\pi}{2} \right\}}$.

38. Use the identity $1 + \tan^2 \theta = \sec^2 \theta$ to write the original equation as

$$\tan^2 \theta + \tan \theta + 1 = 0.$$

Completing the square on the left-hand side then yields

$$\left(\tan \theta + \frac{1}{2} \right)^2 + \frac{3}{4} = 0.$$

This latter equation has no solution, so the original equation also has no solution.

39. First, multiply both sides of the original equation by $\frac{\sqrt{2}}{2}$ to obtain

$$\frac{\sqrt{2}}{2} \sin \theta + \frac{\sqrt{2}}{2} \cos \theta = 0.$$

Next, note that

$$\sin \frac{\pi}{4} = \cos \frac{\pi}{4} = \frac{\sqrt{2}}{2},$$

so that

$$\frac{\sqrt{2}}{2} \sin \theta + \frac{\sqrt{2}}{2} \cos \theta = \sin \frac{\pi}{4} \sin \theta + \cos \frac{\pi}{4} \cos \theta = \cos \left(\theta - \frac{\pi}{4} \right).$$

The equation to be solved has therefore been reduced to

$$\cos \left(\theta - \frac{\pi}{4} \right) = 0.$$

The angles that satisfy this last expression are of the form $(2k+1)\frac{\pi}{2}$, where k is any integer, so

$$\theta - \frac{\pi}{4} = (2k+1)\frac{\pi}{2} \quad \text{or} \quad \theta = (2k+1)\frac{\pi}{2} + \frac{\pi}{4},$$

where k is any integer. Among these angles, the ones that are in the interval $[0, 2\pi)$ are $\frac{3\pi}{4}$ and $\frac{7\pi}{4}$.

The solution set is therefore $\boxed{\left\{ \frac{3\pi}{4}, \frac{7\pi}{4} \right\}}$.

40. Multiplying both sides of the original equation by $\tan \theta$ and using the identity $\tan \theta \cot \theta = 1$ yields

$$\tan^2 \theta = 1 \quad \text{so that} \quad \tan \theta = \pm 1.$$

The angles that satisfy the equation $\tan \theta = 1$ are of the form $\frac{\pi}{4} + k\pi$, while the angles that satisfy the equation $\tan \theta = -1$ are of the form $\frac{3\pi}{4} + k\pi$, where k is any integer. Among all of these angles, the ones that are in the interval $[0, 2\pi)$ are $\frac{\pi}{4}$, $\frac{3\pi}{4}$, $\frac{5\pi}{4}$, and $\frac{7\pi}{4}$. The solution set is therefore $\boxed{\left\{ \frac{\pi}{4}, \frac{3\pi}{4}, \frac{5\pi}{4}, \frac{7\pi}{4} \right\}}$.

41. Use the identity $\cos(2\theta) = 1 - 2\sin^2\theta$ to write the original equation as

$$1 - 2\sin^2\theta + 6\sin^2\theta = 4.$$

Thus

$$\sin^2\theta = \frac{3}{4}, \quad \text{or} \quad \sin\theta = \pm\frac{\sqrt{3}}{2}.$$

The angles whose sine is $\pm\frac{\sqrt{3}}{2}$ are of the form $\pm\frac{\pi}{3} + 2k\pi$ and $\pm\frac{2\pi}{3} + 2k\pi$, where k is any integer.

Among these angles, the ones that are in the interval $[0, 2\pi)$ are $\frac{\pi}{3}$, $\frac{2\pi}{3}$, $\frac{4\pi}{3}$, and $\frac{5\pi}{3}$. The solution set

is therefore $\left\{ \frac{\pi}{3}, \frac{2\pi}{3}, \frac{4\pi}{3}, \frac{5\pi}{3} \right\}$.

42. Use the identity $\cos(2\theta) = 2\cos^2\theta - 1$ to write the original equation as

$$2\cos^2\theta - \cos\theta - 1 = 0.$$

Factoring the left-hand side yields

$$(2\cos\theta + 1)(\cos\theta - 1) = 0,$$

so that $\cos\theta = -\frac{1}{2}$ or $\cos\theta = 1$. The angles that satisfy the former equation are of the form $\pm\frac{2\pi}{3} + 2k\pi$, and the angles that satisfy the latter equation are of the form $2k\pi$, where k is any integer. Among these angles, the ones that are in the interval $[0, 2\pi)$ are 0 , $\frac{2\pi}{3}$, and $\frac{4\pi}{3}$. The solution set is therefore

$$\left\{ 0, \frac{2\pi}{3}, \frac{4\pi}{3} \right\}.$$

43. Use the identity $\sin(4\theta) = 2\sin(2\theta)\cos(2\theta)$ to write the original equation as

$$\sin(2\theta) + 2\sin(2\theta)\cos(2\theta) = \sin(2\theta)(1 + 2\cos(2\theta)) = 0.$$

Thus, $\sin(2\theta) = 0$ or $\cos(2\theta) = -\frac{1}{2}$. The angles whose sine is 0 are of the form $k\pi$, and the angles whose cosine is $-\frac{1}{2}$ are of the form $\pm\frac{2\pi}{3} + 2k\pi$, where k is any integer. It follows that

$$2\theta = k\pi, \quad \text{or} \quad 2\theta = \pm\frac{2\pi}{3} + 2k\pi,$$

so that

$$\theta = \frac{k\pi}{2}, \quad \text{or} \quad \theta = \pm\frac{\pi}{3} + k\pi.$$

Among these angles, the ones that are in the interval $[0, 2\pi)$ are

$$0, \frac{\pi}{3}, \frac{\pi}{2}, \frac{2\pi}{3}, \pi, \frac{4\pi}{3}, \frac{3\pi}{2}, \text{ and } \frac{5\pi}{3}.$$

The solution set is therefore

$$\left\{ 0, \frac{\pi}{3}, \frac{\pi}{2}, \frac{2\pi}{3}, \pi, \frac{4\pi}{3}, \frac{3\pi}{2}, \frac{5\pi}{3} \right\}.$$

44. Using the identities for the cosine of a sum and a difference of two angles,

$$\cos(4\theta) = \cos(5\theta - \theta) = \cos(5\theta)\cos\theta + \sin(5\theta)\sin\theta$$

and

$$\cos(6\theta) = \cos(5\theta + \theta) = \cos(5\theta)\cos\theta - \sin(5\theta)\sin\theta.$$

Subtracting the latter equation from the former yields

$$\cos(4\theta) - \cos(6\theta) = 2 \sin(5\theta) \sin \theta,$$

so that the original equation is equivalent to $2 \sin(5\theta) \sin \theta = 0$. Thus $\sin(5\theta) = 0$ or $\sin \theta = 0$. The angles whose sine is 0 are of the form $k\pi$, where k is any integer. Thus,

$$\theta = \frac{k\pi}{5} \quad \text{or} \quad \theta = k\pi.$$

Among these angles, the ones that are in the interval $[0, 2\pi)$ are

$$0, \frac{\pi}{5}, \frac{2\pi}{5}, \frac{3\pi}{5}, \frac{4\pi}{5}, \pi, \frac{6\pi}{5}, \frac{7\pi}{5}, \frac{8\pi}{5}, \text{ and } \frac{9\pi}{5}.$$

The solution set is therefore

$$\left\{ 0, \frac{\pi}{5}, \frac{2\pi}{5}, \frac{3\pi}{5}, \frac{4\pi}{5}, \pi, \frac{6\pi}{5}, \frac{7\pi}{5}, \frac{8\pi}{5}, \frac{9\pi}{5} \right\}.$$

45. To three decimal places, $\tan^{-1} 5 = 1.373$. The angles whose tangent is 5 are therefore of the form $1.373 + k\pi$, where k is any integer. Among these angles, the ones that are in the interval $[0, 2\pi)$ are 1.373 and $1.373 + \pi = 4.515$. The solution set is then $\{1.373, 4.515\}$.
46. To three decimal places, $\cos^{-1} 0.6 = 0.927$. The angles whose cosine is 0.6 are therefore of the form $\pm 0.927 + 2k\pi$, where k is any integer. Among these angles, the ones that are in the interval $[0, 2\pi)$ are 0.927 and $-0.927 + 2\pi = 5.356$. The solution set is then $\{0.927, 5.356\}$.
47. The equation $2 + 3 \sin \theta = 0$ is equivalent to $\sin \theta = -\frac{2}{3}$. To three decimal places, $\sin^{-1}(-\frac{2}{3}) = -0.730$. The angles whose sine is $-\frac{2}{3}$ are therefore of the form $-0.730 + 2k\pi$ or $\pi - (-0.730) + 2k\pi$, where k is any integer. Among these angles, the ones that are in the interval $[0, 2\pi)$ are $\pi - (-0.730) = 3.871$ and $-0.730 + 2\pi = 5.553$. The solution set is then $\{3.871, 5.553\}$.
48. The equation $4 + \sec \theta = 0$ is equivalent to $\sec \theta = -4$, or $\cos \theta = -0.25$. To three decimal places, $\cos^{-1}(-0.25) = 1.823$. The angles whose cosine is -0.25 are therefore of the form $\pm 1.823 + 2k\pi$. Among these angles, the ones that are in the interval $[0, 2\pi)$ are 1.823 and $-1.823 + 2\pi = 4.460$. The solution set is then $\{1.823, 4.460\}$.
49. (a) In the figure below, the solid curve represents the graph of $f(x) = 3 \sin(2x) + 2$, and the dashed curve represents the graph of $g(x) = \frac{7}{2}$.

- (b) Solving $3\sin(2x) + 2 = \frac{7}{2}$ for $\sin(2x)$ yields $\sin(2x) = \frac{1}{2}$. The angles whose sine is $\frac{1}{2}$ are of the form $\frac{\pi}{6} + 2k\pi$ and $\frac{5\pi}{6} + 2k\pi$, where k is any integer. Thus,

$$x = \frac{\pi}{12} + k\pi \quad \text{or} \quad x = \frac{5\pi}{12} + k\pi.$$

Among these angles, the ones that are in the interval $[0, \pi]$ are $\frac{\pi}{12}$ and $\frac{5\pi}{12}$. The points of intersection,

$$\left(\frac{\pi}{12}, \frac{7}{2}\right) \quad \text{and} \quad \left(\frac{5\pi}{12}, \frac{7}{2}\right)$$

are labeled on the graph in part (a).

- (c) The region bounded by the graphs of $f(x) = 3\sin(2x) + 2$ and $g(x) = \frac{7}{2}$ between the points of intersection determined in part (b) is shaded in the graph drawn in part (a).
- (d) Based on the shaded region in the graph in part (a), on the interval $[0, \pi]$, the solution set for the inequality $f(x) > g(x)$ is $\left\{x \mid \frac{\pi}{12} < x < \frac{5\pi}{12}\right\}$.
50. (a) In the figure below, the solid curve represents the graph of $f(x) = -4\cos x$, and the dashed curve represents the graph of $g(x) = 2\cos x + 3$.

- (b) Solving $-4\cos x = 2\cos x + 3$ for $\cos x$ yields $\cos x = -\frac{1}{2}$. The angles whose cosine is $-\frac{1}{2}$ are of the form $\pm\frac{2\pi}{3} + 2k\pi$, where k is any integer. Among these angles, the ones that are in the interval $[0, 2\pi]$ are $\frac{2\pi}{3}$ and $\frac{4\pi}{3}$. The points of intersection,

$$\left(\frac{2\pi}{3}, 2\right) \quad \text{and} \quad \left(\frac{4\pi}{3}, 2\right)$$

are labeled on the graph in part (a).

- (c) The region bounded by the graphs of $f(x) = -4\cos x$ and $g(x) = 2\cos x + 3$ between the points of intersection determined in part (b) is shaded in the graph drawn in part (a).
- (d) Based on the shaded region in the graph in part (a), on the interval $[0, 2\pi]$, the solution set for the inequality $f(x) > g(x)$ is $\left\{x \mid \frac{2\pi}{3} < x < \frac{4\pi}{3}\right\}$.

Chapter 1: Limits and Continuity

1.1: Limits of Functions Using Numerical and Graphical Techniques

Concepts and Vocabulary

1. The limit as x approaches c of a function f is written symbolically as $\boxed{(c) \lim_{x \rightarrow c} f(x)}$.
2. $\boxed{\text{True}}$. The tangent line to the graph of f at a point $P = (c, f(c))$ is the limiting position of the secant lines passing through P and a point $(x, f(x))$, $x \neq c$, as x moves closer to c .
3. $\boxed{\text{False}}$. If f is not defined at $x = c$, the $\lim_{x \rightarrow c} f(x)$ **may** exist.
4. $\boxed{\text{False}}$. The limit L of a function $y = f(x)$ as x approaches the number c **does not** depend on the value of f at c .
5. If $\lim_{x \rightarrow c} \frac{f(x) - f(c)}{x - c}$ exists, it equals the $\boxed{\text{slope}}$ of the tangent line to the graph of f at the point $(c, f(c))$.
6. $\boxed{\text{False}}$. The limit of a function $y = f(x)$ as x approaches a number c equals L **if and only if both** of the one-sided limits as x approaches c equal L .

Skill Building

7. The values in the table below suggest that the value of $f(x) = 2x$ can be made “as close as we please” to 2 by choosing x “sufficiently close” to 1. It therefore appears that

$$\lim_{x \rightarrow 1} (2x) = \boxed{2}.$$

x	0.9	0.99	0.999	$\rightarrow 1 \leftarrow$	1.001	1.01	1.1
$f(x) = 2x$	1.8	1.98	1.998	$f(x)$ approaches 2	2.002	2.02	2.2

8. The values in the table below suggest that the value of $f(x) = x + 3$ can be made “as close as we please” to 5 by choosing x “sufficiently close” to 2. It therefore appears that

$$\lim_{x \rightarrow 2} (x + 3) = \boxed{5}.$$

x	1.9	1.99	1.999	$\rightarrow 2 \leftarrow$	2.001	2.01	2.1
$f(x) = x + 3$	4.9	4.99	4.999	$f(x)$ approaches 5	5.001	5.01	5.1

9. The values in the table below suggest that the value of $f(x) = x^2 + 2$ can be made “as close as we please” to 2 by choosing x “sufficiently close” to 0. It therefore appears that

$$\lim_{x \rightarrow 0} (x^2 + 2) = \boxed{2}.$$

x	-0.1	-0.01	-0.001	$\rightarrow 0 \leftarrow$	0.001	0.01	0.1
$f(x) = x^2 + 2$	2.01	2.0001	2.000001	$f(x)$ approaches 2	2.000001	2.0001	2.01

10. The values in the table below suggest that the value of $f(x) = x^2 - 2$ can be made “as close as we please” to -1 by choosing x “sufficiently close” to -1 . It therefore appears that

$$\lim_{x \rightarrow -1} (x^2 - 2) = \boxed{-1}.$$

x	-1.1	-1.01	-1.001	$\rightarrow -1 \leftarrow$	-0.999	-0.99	-0.9
$f(x) = x^2 - 2$	-0.79	-0.9799	-0.997999	$f(x)$ approaches -1	-1.001999	-1.0199	-1.19

11. The values in the table below suggest that the value of $f(x) = \frac{x^2 - 9}{x + 3}$ can be made “as close as we please” to -6 by choosing x “sufficiently close” to -3 . It therefore appears that

$$\lim_{x \rightarrow -3} \frac{x^2 - 9}{x + 3} = \boxed{-6}.$$

x	-3.5	-3.1	-3.01	$\rightarrow -3 \leftarrow$	-2.99	-2.9	-2.5
$f(x) = \frac{x^2 - 9}{x + 3}$	-6.5	-6.1	-6.01	$f(x)$ approaches -6	-5.99	-5.9	-5.5

12. The values in the table below suggest that the value of $f(x) = \frac{x^3 + 1}{x + 1}$ can be made “as close as we please” to 3 by choosing x “sufficiently close” to -1 . It therefore appears that

$$\lim_{x \rightarrow -1} \frac{x^3 + 1}{x + 1} = \boxed{3}.$$

x	-1.1	-1.01	-1.001	$\rightarrow -1 \leftarrow$	-0.999	-0.99	-0.9
$f(x) = \frac{x^3 + 1}{x + 1}$	3.31	3.0301	3.003001	$f(x)$ approaches 3	2.997001	2.9701	2.71

13. The values in the table below, which have been rounded to five decimal places for display purposes, suggest that the value of $f(x) = \frac{2 - 2e^x}{x}$ can be made “as close as we please” to -2 by choosing x “sufficiently close” to 0 . It therefore appears that

$$\lim_{x \rightarrow 0} \frac{2 - 2e^x}{x} = \boxed{-2}.$$

x	-0.2	-0.1	-0.01	$\rightarrow 0 \leftarrow$	0.01	0.1	0.2
$f(x) = \frac{2 - 2e^x}{x}$	-1.81269	-1.90325	-1.99003	$f(x)$ approaches -2	-2.01003	-2.10342	-2.21403

14. The values in the table below, which have been rounded to five decimal places for display purposes, suggest that the value of $f(x) = \frac{\ln x}{x - 1}$ can be made “as close as we please” to 1 by choosing x “sufficiently close” to 1 . It therefore appears that

$$\lim_{x \rightarrow 1} \frac{\ln x}{x - 1} = \boxed{1}.$$

x	0.9	0.99	0.999	$\rightarrow 1 \leftarrow$	1.001	1.01	1.1
$f(x) = \frac{\ln x}{x - 1}$	1.05361	1.00503	1.00050	$f(x)$ approaches 1	0.99950	0.99503	0.95310

15. The values in the table below, which have been rounded to five decimal places for display purposes, suggest that the value of $f(x) = \frac{1 - \cos x}{x}$ can be made “as close as we please” to 0 by choosing x “sufficiently close” to 0. It therefore appears that

$$\lim_{x \rightarrow 0} \frac{1 - \cos x}{x} = \boxed{0}.$$

x	-0.2	-0.1	-0.01	$\rightarrow 0 \leftarrow$	0.01	0.1	0.2
$f(x) = \frac{1 - \cos x}{x}$	-0.09967	-0.04996	-0.00500	$f(x)$ approaches 0	0.00500	0.04996	0.09967

16. The values in the table below, which have been rounded to five decimal places for display purposes, suggest that the value of $f(x) = \frac{\sin x}{1 + \tan x}$ can be made “as close as we please” to 0 by choosing x “sufficiently close” to 0. It therefore appears that

$$\lim_{x \rightarrow 0} \frac{\sin x}{1 + \tan x} = \boxed{0}.$$

x	-0.2	-0.1	-0.01	$\rightarrow 0 \leftarrow$	0.01	0.1	0.2
$f(x) = \frac{\sin x}{1 + \tan x}$	-0.24918	-0.11097	-0.01010	$f(x)$ approaches 0	0.00990	0.09073	0.16518

17. The graph suggests that the value of f approaches 2 as x approaches 2 from the left and as x approaches 2 from the right. Thus,

(a) $\lim_{x \rightarrow 2^-} f(x) = \boxed{2};$

(b) $\lim_{x \rightarrow 2^+} f(x) = \boxed{2};$ and

(c) $\lim_{x \rightarrow 2} f(x) = \boxed{2}.$

18. The graph suggests that the value of f approaches 4 as x approaches 2 from the left and as x approaches 2 from the right. Thus,

(a) $\lim_{x \rightarrow 2^-} f(x) = \boxed{4};$

(b) $\lim_{x \rightarrow 2^+} f(x) = \boxed{4};$ and

(c) $\lim_{x \rightarrow 2} f(x) = \boxed{4}.$

19. The graph suggests that the value of f approaches 3 as x approaches 2 from the left but the value of f approaches 6 as x approaches 2 from the right. Thus,

(a) $\lim_{x \rightarrow 2^-} f(x) = \boxed{3};$

(b) $\lim_{x \rightarrow 2^+} f(x) = \boxed{6};$ and

(c) $\lim_{x \rightarrow 2} f(x)$ does not exist because there is no single number that the values of f approach when x is close to 2.

20. The graph suggests that the value of f approaches 4 as x approaches 2 from the left but the value of f approaches 2 as x approaches 2 from the right. Thus,

(a) $\lim_{x \rightarrow 2^-} f(x) = \boxed{4};$

(b) $\lim_{x \rightarrow 2^+} f(x) = \boxed{2}$; and

(c) $\lim_{x \rightarrow 2} f(x)$ does not exist because there is no single number that the values of f approach when x is close to 2.

21. The graph suggests that, as x approaches c from the left,

$$\lim_{x \rightarrow c^-} f(x) = 1,$$

while, as x approaches c from the right,

$$\lim_{x \rightarrow c^+} f(x) = 1.$$

Because the two one-sided limits are equal, it follows that

$$\lim_{x \rightarrow c} f(x) = \boxed{1}.$$

22. The graph suggests that, as x approaches c from the left,

$$\lim_{x \rightarrow c^-} f(x) = 1,$$

while, as x approaches c from the right,

$$\lim_{x \rightarrow c^+} f(x) = 1.$$

Because the two one-sided limits are equal, it follows that

$$\lim_{x \rightarrow c} f(x) = \boxed{1}.$$

23. The graph suggests that, as x approaches c from the left,

$$\lim_{x \rightarrow c^-} f(x) = 1,$$

while, as x approaches c from the right,

$$\lim_{x \rightarrow c^+} f(x) = 1.$$

Because the two one-sided limits are equal, it follows that

$$\lim_{x \rightarrow c} f(x) = \boxed{1}.$$

24. The graph suggests that, as x approaches c from the left,

$$\lim_{x \rightarrow c^-} f(x) = 1,$$

while, as x approaches c from the right,

$$\lim_{x \rightarrow c^+} f(x) = 2.$$

Because the two one-sided limits are not equal (that is, there is no single number that the values of f approach when x is close to c), it follows that

$$\lim_{x \rightarrow c} f(x) \text{ does not exist }.$$

25. The graph suggests that, as x approaches c from the left,

$$\lim_{x \rightarrow c^-} f(x) = -1,$$

while, as x approaches c from the right,

$$\lim_{x \rightarrow c^+} f(x) = 1.$$

Because the two one-sided limits are not equal (that is, there is no single number that the values of f approach when x is close to c), it follows that

$$\lim_{x \rightarrow c} f(x) \text{ does not exist.}$$

26. The graph suggests that, as x approaches c from the left,

$$\lim_{x \rightarrow c^-} f(x) = 1,$$

while, as x approaches c from the right,

$$\lim_{x \rightarrow c^+} f(x) = 3.$$

Because the two one-sided limits are not equal (that is, there is no single number that the values of f approach when x is close to c), it follows that

$$\lim_{x \rightarrow c} f(x) \text{ does not exist.}$$

27. The graph suggests that, as x approaches c from the left,

$$\lim_{x \rightarrow c^-} f(x) = 2,$$

while, as x approaches c from the right,

$$\lim_{x \rightarrow c^+} f(x) = 1.$$

Because the two one-sided limits are not equal (that is, there is no single number that the values of f approach when x is close to c), it follows that

$$\lim_{x \rightarrow c} f(x) \text{ does not exist.}$$

28. The graph suggests that, as x approaches c from the left,

$$\lim_{x \rightarrow c^-} f(x) = 1,$$

while, as x approaches c from the right,

$$\lim_{x \rightarrow c^+} f(x) = 2.$$

Because the two one-sided limits are not equal (that is, there is no single number that the values of f approach when x is close to c), it follows that

$$\lim_{x \rightarrow c} f(x) \text{ does not exist.}$$

29. The graph of f shown below suggests that, as x approaches 2 from the left,

$$\lim_{x \rightarrow 2^-} f(x) = 9,$$

while, as x approaches 2 from the right,

$$\lim_{x \rightarrow 2^+} f(x) = 9.$$

Because the two one-sided limits are equal, it follows that

$$\lim_{x \rightarrow 2} f(x) = \boxed{9}.$$

30. The graph of f shown below suggests that, as x approaches 0 from the left,

$$\lim_{x \rightarrow 0^-} f(x) = 1,$$

while, as x approaches 0 from the right,

$$\lim_{x \rightarrow 0^+} f(x) = 0.$$

Because the two one-sided limits are not equal, it follows that

$$\lim_{x \rightarrow 0} f(x) \text{ does not exist}.$$

31. The graph of f shown below suggests that, as x approaches 1 from the left,

$$\lim_{x \rightarrow 1^-} f(x) = 2,$$

while, as x approaches 1 from the right,

$$\lim_{x \rightarrow 1^+} f(x) = 4.$$

Because the two one-sided limits are not equal, it follows that

$$\lim_{x \rightarrow 1} f(x) \text{ does not exist.}$$

32. The graph of f shown below suggests that, as x approaches 2 from the left,

$$\lim_{x \rightarrow 2^-} f(x) = 4,$$

while, as x approaches 2 from the right,

$$\lim_{x \rightarrow 2^+} f(x) = 4.$$

Because the two one-sided limits are equal, it follows that

$$\lim_{x \rightarrow 2} f(x) = 4.$$

33. The graph of f shown below suggests that, as x approaches 1 from the left,

$$\lim_{x \rightarrow 1^-} f(x) = 2,$$

while, as x approaches 1 from the right,

$$\lim_{x \rightarrow 1^+} f(x) = 2.$$

Because the two one-sided limits are equal, it follows that

$$\lim_{x \rightarrow 1} f(x) = \boxed{2}.$$

34. The graph of f shown below suggests that, as x approaches -1 from the left,

$$\lim_{x \rightarrow -1^-} f(x) = -1,$$

while, as x approaches -1 from the right,

$$\lim_{x \rightarrow -1^+} f(x) = 0.$$

Because the two one-sided limits are not equal, it follows that

$$\lim_{x \rightarrow -1} f(x) \text{ does not exist}.$$

35. The graph of f shown below suggests that, as x approaches 0 from the left,

$$\lim_{x \rightarrow 0^-} f(x) = 0,$$

while, as x approaches 0 from the right,

$$\lim_{x \rightarrow 0^+} f(x) = 1.$$

Because the two one-sided limits are not equal, it follows that

$$\lim_{x \rightarrow 0} f(x) \text{ does not exist.}$$

36. The graph of f shown below suggests that, as x approaches 1 from the left,

$$\lim_{x \rightarrow 1^-} f(x) = 1,$$

while, as x approaches 1 from the right,

$$\lim_{x \rightarrow 1^+} f(x) = -1.$$

Because the two one-sided limits are not equal, it follows that

$$\lim_{x \rightarrow 1} f(x) \text{ does not exist.}$$

Applications and Extensions

37. Answers will vary. Below is the graph of a function f for which

$$\lim_{x \rightarrow 2} f(x) = 3; \quad \lim_{x \rightarrow 3^-} f(x) = 3; \quad \lim_{x \rightarrow 3^+} f(x) = 1; \quad f(2) = 3; \quad f(3) = 1.$$

38. Answers will vary. Below is the graph of a function f for which

$$\lim_{x \rightarrow -1} f(x) = 0; \quad \lim_{x \rightarrow 2^-} f(x) = -2; \quad \lim_{x \rightarrow 2^+} f(x) = -2; \quad f(-1) \text{ is not defined}; \quad f(2) = -2.$$

39. Answers will vary. Below is the graph of a function f for which

$$\lim_{x \rightarrow 1} f(x) = 4; \quad \lim_{x \rightarrow 0^-} f(x) = -1; \quad \lim_{x \rightarrow 0^+} f(x) = 0; \quad f(0) = -1; \quad f(1) = 2.$$

40. Answers will vary. Below is the graph of a function f for which

$$\lim_{x \rightarrow 2} f(x) = 2; \quad \lim_{x \rightarrow -1} f(x) = 0; \quad \lim_{x \rightarrow 1} f(x) = 1; \quad f(-1) = 1; \quad f(2) = 3.$$

41. The table of values below suggests $\lim_{x \rightarrow 5^+} \frac{|x-5|}{x-5} = \boxed{1}$.

x	$5 \leftarrow$	5.001	5.01	5.1
$f(x) = \frac{ x-5 }{x-5}$	$f(x)$ approaches 1	1	1	1

Alternately, the graph below suggests $\lim_{x \rightarrow 5^+} \frac{|x-5|}{x-5} = \boxed{1}$.

42. The table of values below suggests $\lim_{x \rightarrow 5^-} \frac{|x-5|}{x-5} = \boxed{-1}$.

x	4.9	4.99	4.999	$\rightarrow 5$
$f(x) = \frac{ x-5 }{x-5}$	-1	-1	-1	$f(x)$ approaches -1

Alternately, the graph below suggests $\lim_{x \rightarrow 5^-} \frac{|x-5|}{x-5} = \boxed{-1}$.

43. The table of values below suggests $\lim_{x \rightarrow (\frac{1}{2})^-} \lfloor 2x \rfloor = \boxed{0}$.

x	0.4	0.49	0.499	$\rightarrow \frac{1}{2}$
$f(x) = \lfloor 2x \rfloor$	0	0	0	$f(x)$ approaches 0

Alternately, the graph below suggests $\lim_{x \rightarrow (\frac{1}{2})^-} \lfloor 2x \rfloor = \boxed{0}$.

44. The table of values below suggests $\lim_{x \rightarrow (\frac{1}{2})^+} \lfloor 2x \rfloor = \boxed{1}$.

x	$\frac{1}{2} \leftarrow$	0.501	0.51	0.6
$f(x) = \lfloor 2x \rfloor$	$f(x)$ approaches 1	1	1	1

Alternately, the graph below suggests $\lim_{x \rightarrow (\frac{1}{2})^+} \lfloor 2x \rfloor = \boxed{1}$.

45. The table of values below suggests $\lim_{x \rightarrow (\frac{2}{3})^-} \lfloor 2x \rfloor = \boxed{1}$.

x	0.6	0.66	0.666	$\rightarrow \frac{2}{3}$
$f(x) = \lfloor 2x \rfloor$	1	1	1	$f(x)$ approaches 1

Alternately, the graph below suggests $\lim_{x \rightarrow (\frac{2}{3})^-} \lfloor 2x \rfloor = \boxed{1}$.

46. The table of values below suggests $\lim_{x \rightarrow (\frac{2}{3})^+} [2x] = \boxed{1}$.

x	$\frac{2}{3} \leftarrow$	0.667	0.67	0.7
$f(x) = [2x]$	$f(x)$ approaches 1	1	1	1

Alternately, the graph below suggests $\lim_{x \rightarrow (\frac{2}{3})^+} [2x] = \boxed{1}$.

47. The table of values below suggests $\lim_{x \rightarrow 2^+} \sqrt{|x| - x} = \boxed{0}$.

x	$2 \leftarrow$	2.001	2.01	2.1
$f(x) = \sqrt{ x - x}$	$f(x)$ approaches 0	0	0	0

Alternately, the graph below suggests $\lim_{x \rightarrow 2^+} \sqrt{|x| - x} = \boxed{0}$.

48. The table of values below suggests $\lim_{x \rightarrow 2^-} \sqrt{|x| - x} = \boxed{0}$.

x	1.9	1.99	1.999	$\rightarrow 2$
$f(x) = \sqrt{ x - x}$	0	0	0	$f(x)$ approaches 0

Alternately, the graph below suggests $\lim_{x \rightarrow 2^-} \sqrt{|x| - x} = \boxed{0}$.

49. The table of values below suggests $\lim_{x \rightarrow 2^+} \sqrt[3]{[x] - x} = \boxed{0}$.

x	$2 \leftarrow$	2.000000001	2.000001	2.001
$f(x) = \sqrt[3]{[x] - x}$	$f(x)$ approaches 0	-0.001	-0.01	-0.1

Alternately, the graph below suggests $\lim_{x \rightarrow 2^+} \sqrt[3]{[x] - x} = \boxed{0}$.

50. The table of values below, in which the function values have been rounded to five decimal places for display purposes, suggests $\lim_{x \rightarrow 2^-} \sqrt[3]{[x]} - x = \boxed{-1}$.

x	1.9	1.99	1.999	$\rightarrow 2$
$f(x) = \sqrt[3]{[x]} - x$	-0.96549	-0.99666	-0.99967	$f(x)$ approaches -1

Alternately, the graph below suggests $\lim_{x \rightarrow 2^-} \sqrt[3]{[x]} - x = \boxed{-1}$.

51. (a) The secant line containing the points (2, 12) and (3, 27) has a slope of

$$m_{\text{sec}} = \frac{27 - 12}{3 - 2} = \frac{15}{1} = \boxed{15}.$$

- (b) The secant line containing the points (2, 12) and $(x, f(x))$ for $x \neq 2$ has a slope of

$$m_{\text{sec}} = \frac{3x^2 - 12}{x - 2} = \frac{3(x - 2)(x + 2)}{x - 2} = \boxed{3(x + 2)}.$$

- (c) The values in the table below suggest that the slope of the tangent line to the graph of f at 2 is

$$\lim_{x \rightarrow 2} m_{\text{sec}} = \boxed{12}.$$

x	1.9	1.99	1.999	$\rightarrow 2 \leftarrow$	2.001	2.01	2.1
m_{sec}	11.7	11.97	11.997	m_{sec} approaches 12	12.003	12.03	12.3

- (d) The secant line from part (a) has slope 15 and passes through the point $(2, 12)$. The equation of this secant line is therefore

$$y - 12 = 15(x - 2) \quad \text{or} \quad y = 15x - 18.$$

The tangent line at $x = 2$ has slope 12 and also passes through the point $(2, 12)$; the equation of this line is

$$y - 12 = 12(x - 2) \quad \text{or} \quad y = 12x - 12.$$

The figure below displays the graph of f as the solid curve, the graph of the tangent line as the dashed curve, and the graph of the secant line as the dotted curve.

52. (a) The secant line containing the points $(2, 8)$ and $(3, 27)$ has a slope of

$$m_{\text{sec}} = \frac{27 - 8}{3 - 2} = \frac{19}{1} = \boxed{19}.$$

- (b) The secant line containing the points $(2, 8)$ and $(x, f(x))$ for $x \neq 2$ has a slope of

$$m_{\text{sec}} = \frac{x^3 - 8}{x - 2} = \frac{(x - 2)(x^2 + 2x + 4)}{x - 2} = \boxed{x^2 + 2x + 4}.$$

- (c) The values in the table below suggest that the slope of the tangent line to the graph of f at 2 is

$$\lim_{x \rightarrow 2} m_{\text{sec}} = \boxed{12}.$$

x	1.9	1.99	1.999	$\rightarrow 2 \leftarrow$	2.001	2.01	2.1
m_{sec}	11.41	11.9401	11.994001	m_{sec} approaches 12	12.006001	12.0601	12.61

- (d) The secant line from part (a) has slope 19 and passes through the point $(2, 8)$. The equation of this secant line is therefore

$$y - 8 = 19(x - 2) \quad \text{or} \quad y = 19x - 30.$$

The tangent line at $x = 2$ has slope 12 and also passes through the point $(2, 8)$; the equation of this line is

$$y - 8 = 12(x - 2) \quad \text{or} \quad y = 12x - 16.$$

The figure below displays the graph of f as the solid curve, the graph of the tangent line as the dashed curve, and the graph of the secant line as the dotted curve.

53. (a) Let $f(x) = \frac{1}{2}x^2 - 1$. The slope of the secant line containing the points $P = (2, f(2))$ and $Q = (2 + h, f(2 + h))$ is

$$\begin{aligned} m_{\text{sec}} &= \frac{f(2+h) - f(2)}{(2+h) - 2} = \frac{\frac{1}{2}(2+h)^2 - 1 - (\frac{1}{2}2^2 - 1)}{h} \\ &= \frac{\frac{1}{2}(4 + 4h + h^2) - 1 - \frac{1}{2}2^2 + 1}{h} = \frac{2 + 2h + \frac{1}{2}h^2 - 2}{h} = \frac{2h + \frac{1}{2}h^2}{h} = \boxed{2 + \frac{1}{2}h}, \end{aligned}$$

provided $h \neq 0$.

- (b) Using the result from part (a),

h	-0.5	-0.1	-0.001	0.001	0.1	0.5
m_{sec}	1.75	1.95	1.9995	2.0005	2.05	2.25

- (c) The table from part (b) suggests that $\lim_{h \rightarrow 0} m_{\text{sec}} = \boxed{2}$.
- (d) Because the limit of the slope of the secant line is 2, the slope of the line tangent to the graph of f at the point $P = (2, f(2))$ is $\boxed{2}$.
- (e) The tangent line to f at the point $P = (2, f(2))$ has slope 2 and contains the point $(2, f(2)) = (2, 1)$. The equation of the tangent line is therefore

$$y - 1 = 2(x - 2) \quad \text{or} \quad y = 2x - 3.$$

The figure below displays the graph of f as the solid curve and the graph of the tangent line as the dashed curve.

54. (a) Let $f(x) = x^2 - 1$. The slope of the secant line containing the points $P = (-1, f(-1))$ and $Q = (-1 + h, f(-1 + h))$ is

$$\begin{aligned} m_{\text{sec}} &= \frac{f(-1 + h) - f(-1)}{(-1 + h) - (-1)} = \frac{(-1 + h)^2 - 1 - ((-1)^2 - 1)}{h} \\ &= \frac{1 - 2h + h^2 - 1 - 1 + 1}{h} = \frac{-2h + h^2}{h} = \boxed{-2 + h}, \end{aligned}$$

provided $h \neq 0$.

- (b) Using the result from part (a),

h	-0.1	-0.01	-0.001	-0.0001	0.0001	0.001	0.01	0.1
m_{sec}	-2.1	-2.01	-2.001	-2.0001	-1.9999	-1.999	-1.99	-1.9

- (c) The table from part (b) suggests that $\lim_{h \rightarrow 0} m_{\text{sec}} = \boxed{-2}$.
- (d) Because the limit of the slope of the secant line is -2 , the slope of the line tangent to the graph of f at the point $P = (-1, f(-1))$ is $\boxed{-2}$.
- (e) The tangent line to f at the point $P = (-1, f(-1))$ has slope -2 and contains the point $(-1, f(-1)) = (-1, 0)$. The equation of the tangent line is therefore

$$y - 0 = -2(x + 1) \quad \text{or} \quad y = -2x - 2.$$

The figure below displays the graph of f as the solid curve and the graph of the tangent line as the dashed curve.

55. (a) The values in the table below suggest that

$$\lim_{x \rightarrow 0} \cos \frac{\pi}{x} = \boxed{1}.$$

x	$-\frac{1}{2}$	$-\frac{1}{4}$	$-\frac{1}{8}$	$-\frac{1}{10}$	$-\frac{1}{12}$	$\rightarrow 0 \leftarrow$	$\frac{1}{12}$	$\frac{1}{10}$	$\frac{1}{8}$	$\frac{1}{4}$	$\frac{1}{2}$
$f(x) = \cos \frac{\pi}{x}$	1	1	1	1	1	$f(x)$ approaches 1	1	1	1	1	1

- (b) The values in the table below suggest that

$$\lim_{x \rightarrow 0} \cos \frac{\pi}{x} = \boxed{-1}.$$

x	-1	$-\frac{1}{3}$	$-\frac{1}{5}$	$-\frac{1}{7}$	$-\frac{1}{9}$	$\rightarrow 0 \leftarrow$	$\frac{1}{9}$	$\frac{1}{7}$	$\frac{1}{5}$	$\frac{1}{3}$	1
$f(x) = \cos \frac{\pi}{x}$	-1	-1	-1	-1	-1	f approaches	-1	-1	-1	-1	-1

- (c) Because the values obtained in parts (a) and (b) are not equal, we conclude the limit does not exist. As x gets closer to 0, the argument to the cosine function, $\frac{\pi}{x}$, becomes unbounded. Consequently, the cosine function oscillates repeatedly between -1 and 1 and never approaches a single value. A table of values can be a useful tool for investigating a limit, but should only be viewed as providing evidence of a possible value for a limit. A final conclusion regarding a limit should be based on the properties of limits that will be developed in subsequent sections of this chapter.
- (d) The figure below left displays the graph of f with an x -window of $(-2\pi, 2\pi)$, and the figure below right displays the graph of f with an x -window of $(-0.1, 0.1)$. Using either graph, it appears that $\lim_{x \rightarrow 0} f(x)$ does not exist because the function value does not approach a single number. Instead, the function seems to oscillate more rapidly between -1 and 1 as x gets closer to 0.

56. (a) The values in the table below suggest that

$$\lim_{x \rightarrow 0} \cos \frac{\pi}{x^2} = \boxed{1}.$$

x	-0.1	-0.01	-0.001	-0.0001	$\rightarrow 0 \leftarrow$	0.0001	0.001	0.01	0.1
$f(x) = \cos \frac{\pi}{x^2}$	1	1	1	1	$f(x)$ approaches	1	1	1	1

- (b) The values in the table below suggest that

$$\lim_{x \rightarrow 0} \cos \frac{\pi}{x^2} = \boxed{\frac{\sqrt{2}}{2}}.$$

x	$-\frac{2}{3}$	$-\frac{2}{5}$	$-\frac{2}{7}$	$-\frac{2}{9}$	$\rightarrow 0 \leftarrow$	$\frac{2}{9}$	$\frac{2}{7}$	$\frac{2}{5}$	$\frac{2}{3}$
$f(x) = \cos \frac{\pi}{x^2}$	$\frac{\sqrt{2}}{2}$	$\frac{\sqrt{2}}{2}$	$\frac{\sqrt{2}}{2}$	$\frac{\sqrt{2}}{2}$	$f(x)$ approaches	$\frac{\sqrt{2}}{2}$	$\frac{\sqrt{2}}{2}$	$\frac{\sqrt{2}}{2}$	$\frac{\sqrt{2}}{2}$

- (c) Because the values obtained in parts (a) and (b) are not equal, we conclude the limit does not exist. As x gets closer to 0, the argument to the cosine function, $\frac{\pi}{x^2}$, becomes unbounded. Consequently, the cosine function oscillates repeatedly between -1 and 1 and never approaches a single value. A table of values can be a useful tool for investigating a limit, but should only be viewed as providing evidence of a possible value for a limit. A final conclusion regarding a limit should be based on the properties of limits that will be developed in subsequent sections of this chapter.

- (d) The figure below left displays the graph of f with an x -window of $(-2\pi, 2\pi)$, and the figure below right displays the graph of f with an x -window of $(-1, 1)$. Using either graph, it appears that $\lim_{x \rightarrow 0} f(x)$ does not exist because the function value does not approach a single number. Instead, the function seems to oscillate more rapidly between -1 and 1 as x gets closer to 0 .

57. (a) The values in the table below suggest that

$$\lim_{x \rightarrow 2} \frac{x-8}{2} = \boxed{-3}.$$

x	1.9	1.99	1.999	$\rightarrow 2 \leftarrow$	2.001	2.01	2.1
$f(x) = \frac{x-8}{2}$	-3.05	-3.005	-3.0005	$f(x)$ approaches -3	-2.9995	-2.995	-2.95

- (b) The function $f(x) = \frac{x-8}{2}$ is within 0.1 of -3 provided $|f(x) - (-3)| \leq 0.1$; that is,

$$\begin{aligned} \left| \frac{x-8}{2} + 3 \right| &\leq 0.1 \\ |(x-8) + 6| &\leq 0.2 \\ |x-2| &\leq 0.2. \end{aligned}$$

Thus, if $\boxed{1.8 \leq x \leq 2.2}$, then $f(x)$ is within 0.1 of -3 .

- (c) The function $f(x) = \frac{x-8}{2}$ is within 0.01 of -3 provided $|f(x) - (-3)| \leq 0.01$; that is,

$$\begin{aligned} \left| \frac{x-8}{2} + 3 \right| &\leq 0.01 \\ |(x-8) + 6| &\leq 0.02 \\ |x-2| &\leq 0.02. \end{aligned}$$

Thus, if $\boxed{1.98 \leq x \leq 2.02}$, then $f(x)$ is within 0.01 of -3 .

58. (a) The values in the table below suggest that

$$\lim_{x \rightarrow 2} (5 - 2x) = \boxed{1}.$$

x	1.9	1.99	1.999	$\rightarrow 2 \leftarrow$	2.001	2.01	2.1
$f(x) = 5 - 2x$	1.2	1.02	1.002	$f(x)$ approaches 1	0.998	0.98	0.8

- (b) The function $f(x) = 5 - 2x$ is within 0.1 of 1 provided $|f(x) - 1| \leq 0.1$; that is,

$$\begin{aligned} |(5 - 2x) - 1| &\leq 0.1 \\ |4 - 2x| &\leq 0.1 \\ |-2(x - 2)| &\leq 0.1 \\ |x - 2| &\leq 0.05. \end{aligned}$$

Thus, if $\boxed{1.95 \leq x \leq 2.05}$, then $f(x)$ is within 0.1 of 1.

- (c) The function $f(x) = 5 - 2x$ is within 0.01 of 1 provided $|f(x) - 1| \leq 0.01$; that is,

$$\begin{aligned} |(5 - 2x) - 1| &\leq 0.01 \\ |4 - 2x| &\leq 0.01 \\ |-2(x - 2)| &\leq 0.01 \\ |x - 2| &\leq 0.005. \end{aligned}$$

Thus, if $\boxed{1.995 \leq x \leq 2.005}$, then $f(x)$ is within 0.01 of 1.

59. (a) Because the Postal Service rounds the weight of the letter up to the next whole number of ounces, the first-class postage charged is

$$C(w) = \begin{cases} 0.46, & \text{if } 0 < w \leq 1 \\ 0.66, & \text{if } 1 < w \leq 2 \\ 0.86, & \text{if } 2 < w \leq 3 \\ 1.06, & \text{if } 3 < w \leq 3.5. \end{cases}$$

where postage is measured in dollars and weight is measured in ounces. This can be written compactly in terms of the ceiling function as

$$C(w) = 0.46 + 0.20\lceil w - 1 \rceil.$$

- (b) The domain of C is the set $\boxed{\{w | 0 < w \leq 3.5\}}$.

- (c) The graph of the postage function C is shown below.

- (d) The graph of C suggests that

$$\boxed{\lim_{w \rightarrow 2^-} C(w) = 0.66 \quad \text{and} \quad \lim_{w \rightarrow 2^+} C(w) = 0.86}.$$

Because these two one-sided limits are not equal, this suggests that $\boxed{\lim_{w \rightarrow 2} C(w) \text{ does not exist}}.$

(e) The graph of C suggests that $\lim_{w \rightarrow 0^+} C(w) = 0.46$.

(f) The graph of C suggests that $\lim_{w \rightarrow 3.5^-} C(w) = 1.06$.

60. (a) Because the Postal Service rounds the weight of the letter up to the next whole number of ounces, the first-class postage charged is

$$C(w) = 0.92 + 0.20 \lceil w - 1 \rceil,$$

for $0 < w \leq 13$, where postage is measured in dollars and weight is measured in ounces.

(b) The domain of C is the set $\{w | 0 < w \leq 13\}$.

(c) The graph of the postage function C is shown below.

(d) The graph of C suggests that

$$\lim_{w \rightarrow 1^-} C(w) = 0.92 \quad \text{and} \quad \lim_{w \rightarrow 1^+} C(w) = 1.12.$$

Because these two one-sided limits are not equal, this suggests that $\lim_{w \rightarrow 1} C(w)$ does not exist.

(e) The graph of C suggests that

$$\lim_{w \rightarrow 12^-} C(w) = 3.12 \quad \text{and} \quad \lim_{w \rightarrow 12^+} C(w) = 3.32.$$

Because these two one-sided limits are not equal, this suggests that $\lim_{w \rightarrow 12} C(w)$ does not exist.

(f) The graph of C suggests that $\lim_{w \rightarrow 0^+} C(w) = 0.92$.

(g) The graph of C suggests that $\lim_{w \rightarrow 13^-} C(w) = 3.32$.

61. Let $S(t)$ denote a student's final exam score as a function of the time t that the student studies.

(a) Professor Smith's claim can be written symbolically as

$$\lim_{t \rightarrow 7} S(t) = 100.$$

(b) Using the ϵ - δ definition of a limit, Professor Smith's can be written as:
 given any $\epsilon > 0$, there is a number $\delta > 0$ so that whenever $0 < |t - 7| < \delta$ then $|S(t) - 100| < \epsilon$.

62. If $h = x - c$, then $x = h + c$ and h approaches zero as x approaches c . Thus,

$$m_{\tan} = \lim_{x \rightarrow c} \frac{f(x) - f(c)}{x - c} = \lim_{h \rightarrow 0} \frac{f(c + h) - f(c)}{(c + h) - c} = \boxed{\lim_{h \rightarrow 0} \frac{f(c + h) - f(c)}{h}}.$$

63. No, the value of the function f **at** $x = 2$ has no bearing on $\lim_{x \rightarrow 2} f(x)$. The limit examines the value of f as x **approaches** 2 but is not equal to 2.

64. No, $\lim_{x \rightarrow 2} f(x)$ conveys no information about the value of f **at** $x = 2$. The limit examines the value of f as x **approaches** 2 but is not equal to 2.

65. (a) Because

$$\frac{x - 3}{3 - x} = \frac{-(3 - x)}{3 - x} = -1$$

provided $x \neq 3$, the graph of $f(x)$ is the horizontal line $y = -1$ excluding the point $(3, -1)$.

- (b) The graph of f (see below) suggests that

$$\boxed{\lim_{x \rightarrow 3^-} f(x) = -1 \quad \text{and} \quad \lim_{x \rightarrow 3^+} f(x) = -1}.$$

- (c) Because the two one-sided limits are equal, the graph suggests that $\lim_{x \rightarrow 3} f(x)$ exists and is equal to -1 .

66. (a) The values in the table below, which have been rounded to five decimal places for display purposes, suggest that

$$\lim_{x \rightarrow 0} (1 + x)^{1/x} \approx \boxed{2.72}.$$

x	-0.01	-0.001	-0.0001	$\rightarrow 0 \leftarrow$	0.0001	0.001	0.01
$f(x) = (1 + x)^{1/x}$	2.731999	2.719642	2.718418		2.718146	2.716924	2.704814

- (b) The figure below left displays the graph of g for $-0.5 \leq x \leq 0.5$. The figure below right displays a closer view of the graph of g , focusing on the y -intercept.

(c) The table in part (a) and the graphs in part (b) all suggest that

$$\lim_{x \rightarrow 0} (1+x)^{1/x} \approx \boxed{2.72}.$$

(d) Using the computer algebra system *Mathematica*,

$$\lim_{x \rightarrow 0} (1+x)^{1/x} = \boxed{e \approx 2.71828}.$$

Challenge Problems

67. The graph of the function f is shown below. Note that except when x is an integer, the graph of f coincides with the x -axis. The graph suggests that

$$\lim_{x \rightarrow 2} f(x) = \boxed{0}.$$

68. The graph of f (see Problem 67) suggests

$$\lim_{x \rightarrow 1/2} f(x) = \boxed{0}.$$

69. The graph of f (see Problem 67) suggests

$$\lim_{x \rightarrow 3} f(x) = \boxed{0}.$$

70. The graph of f (see Problem 67) suggests

$$\lim_{x \rightarrow 0} f(x) = \boxed{0}.$$

1.2: Limits of Functions Using Properties of Limits

Concepts and Vocabulary

- $\lim_{x \rightarrow 4} (-3) = \boxed{-3}$.
 - $\lim_{x \rightarrow 0} \pi = \boxed{\pi}$.
- If $\lim_{x \rightarrow c} f(x) = 3$, then $\lim_{x \rightarrow c} [f(x)]^5 = 3^5 = \boxed{243}$.
- If $\lim_{x \rightarrow c} f(x) = 64$, then $\lim_{x \rightarrow c} \sqrt[3]{f(x)} = \sqrt[3]{64} = \boxed{4}$.
- $\lim_{x \rightarrow -1} x = \boxed{-1}$.
 - $\lim_{x \rightarrow e} x = \boxed{e}$.
- $\lim_{x \rightarrow 0} (x - 2) = 0 - 2 = \boxed{-2}$.
 - $\lim_{x \rightarrow \frac{1}{2}} (3 + x) = 3 + \frac{1}{2} = \boxed{\frac{7}{2}}$.
- $\lim_{x \rightarrow 2} (-3x) = -3(2) = \boxed{-6}$.
 - $\lim_{x \rightarrow 0} (3x) = 3(0) = \boxed{0}$.
- $\boxed{\text{True}}$. If p is a polynomial, then $\lim_{x \rightarrow 5} p(x) = p(5)$.
- If the domain of a rational function R is $\{x | x \neq 0\}$, then $\lim_{x \rightarrow 2} R(x) = R(\boxed{2})$.
- $\boxed{\text{False}}$. Properties of limits **can** be used for one-sided limits.
- $\boxed{\text{True}}$. If $f(x) = \frac{(x+1)(x+2)}{x+1}$ and $g(x) = x+2$, then $\lim_{x \rightarrow -1} f(x) = \lim_{x \rightarrow -1} g(x) = 1$.

Skill Building

$$11. \lim_{x \rightarrow 3} [2(x+4)] = 2 \lim_{x \rightarrow 3} (x+4) = 2 \left[\lim_{x \rightarrow 3} x + \lim_{x \rightarrow 3} 4 \right] = 2(3+4) = \boxed{14}.$$

$$12. \lim_{x \rightarrow -2} [3(x+1)] = 3 \lim_{x \rightarrow -2} (x+1) = 3 \left[\lim_{x \rightarrow -2} x + \lim_{x \rightarrow -2} 1 \right] = 3(-2+1) = \boxed{-3}.$$

13.

$$\begin{aligned} \lim_{x \rightarrow -2} [x(3x-1)(x+2)] &= \lim_{x \rightarrow -2} x \cdot \lim_{x \rightarrow -2} (3x-1) \cdot \lim_{x \rightarrow -2} (x+2) \\ &= \lim_{x \rightarrow -2} x \cdot \left(3 \lim_{x \rightarrow -2} x - \lim_{x \rightarrow -2} 1 \right) \cdot \left(\lim_{x \rightarrow -2} x + \lim_{x \rightarrow -2} 2 \right) \\ &= -2[3(-2) - 1][-2 + 2] = -2(-7)(0) = \boxed{0}. \end{aligned}$$

14.

$$\begin{aligned} \lim_{x \rightarrow -1} [x(x-1)(x+10)] &= \lim_{x \rightarrow -1} x \cdot \lim_{x \rightarrow -1} (x-1) \cdot \lim_{x \rightarrow -1} (x+10) \\ &= \lim_{x \rightarrow -1} x \cdot \left(\lim_{x \rightarrow -1} x - \lim_{x \rightarrow -1} 1 \right) \cdot \left(\lim_{x \rightarrow -1} x + \lim_{x \rightarrow -1} 10 \right) \\ &= -1(-1-1)(-1+10) = -1(-2)(9) = \boxed{18}. \end{aligned}$$

$$15. \lim_{t \rightarrow 1} (3t - 2)^3 = \left[\lim_{t \rightarrow 1} (3t - 2) \right]^3 = [3(1) - 2]^3 = 1^3 = \boxed{1}.$$

$$16. \lim_{x \rightarrow 0} (-3x + 1)^2 = \left[\lim_{x \rightarrow 0} (-3x + 1) \right]^2 = [-3(0) + 1]^2 = 1^2 = \boxed{1}.$$

$$17. \lim_{x \rightarrow 4} 3\sqrt{x} = 3\sqrt{\lim_{x \rightarrow 4} x} = 3\sqrt{4} = \boxed{6}.$$

$$18. \lim_{x \rightarrow 8} \left(\frac{1}{4} \sqrt[3]{x} \right) = \frac{1}{4} \sqrt[3]{\lim_{x \rightarrow 8} x} = \frac{1}{4} \sqrt[3]{8} = \frac{1}{4} \cdot 2 = \boxed{\frac{1}{2}}.$$

$$19. \lim_{x \rightarrow 3} \sqrt{5x - 4} = \sqrt{\lim_{x \rightarrow 3} (5x - 4)} = \sqrt{5(3) - 4} = \boxed{\sqrt{11}}.$$

$$20. \lim_{t \rightarrow 2} \sqrt{3t + 4} = \sqrt{\lim_{t \rightarrow 2} (3t + 4)} = \sqrt{3(2) + 4} = \boxed{\sqrt{10}}.$$

21.

$$\begin{aligned} \lim_{t \rightarrow 2} [t \sqrt{(5t + 3)(t + 4)}] &= \lim_{t \rightarrow 2} t \cdot \lim_{t \rightarrow 2} \sqrt{(5t + 3)(t + 4)} = 2 \sqrt{\lim_{t \rightarrow 2} [(5t + 3)(t + 4)]} \\ &= 2 \sqrt{\lim_{t \rightarrow 2} (5t + 3) \cdot \lim_{t \rightarrow 2} (t + 4)} = 2 \sqrt{(5(2) + 3)(2 + 4)} = \boxed{2\sqrt{78}}. \end{aligned}$$

22.

$$\begin{aligned} \lim_{t \rightarrow -1} [t \sqrt[3]{(t + 1)(2t - 1)}] &= \lim_{t \rightarrow -1} t \cdot \lim_{t \rightarrow -1} \sqrt[3]{(t + 1)(2t - 1)} = -1 \sqrt[3]{\lim_{t \rightarrow -1} [(t + 1)(2t - 1)]} \\ &= - \sqrt[3]{\lim_{t \rightarrow -1} (t + 1) \cdot \lim_{t \rightarrow -1} (2t - 1)} = - \sqrt[3]{(-1 + 1)(2(-1) - 1)} = - \sqrt[3]{0} = \boxed{0}. \end{aligned}$$

23.

$$\begin{aligned} \lim_{x \rightarrow 3} (\sqrt{x} + x + 4)^{1/2} &= \left[\lim_{x \rightarrow 3} (\sqrt{x} + x + 4) \right]^{1/2} = \left[\lim_{x \rightarrow 3} \sqrt{x} + \lim_{x \rightarrow 3} x + \lim_{x \rightarrow 3} 4 \right]^{1/2} \\ &= \left[\sqrt{\lim_{x \rightarrow 3} x} + 3 + 4 \right]^{1/2} = \boxed{(\sqrt{3} + 7)^{1/2}}. \end{aligned}$$

24.

$$\begin{aligned} \lim_{t \rightarrow 2} (t\sqrt{2t} + 4)^{1/3} &= \left[\lim_{t \rightarrow 2} (t\sqrt{2t} + 4) \right]^{1/3} = \left[\lim_{t \rightarrow 2} t\sqrt{2t} + \lim_{t \rightarrow 2} 4 \right]^{1/3} = \left[\lim_{t \rightarrow 2} t \cdot \lim_{t \rightarrow 2} \sqrt{2t} + 4 \right]^{1/3} \\ &= \left[2 \cdot \sqrt{\lim_{t \rightarrow 2} (2t)} + 4 \right]^{1/3} = \left[2\sqrt{2(2)} + 4 \right]^{1/3} = 8^{1/3} = \boxed{2}. \end{aligned}$$

25.

$$\begin{aligned} \lim_{t \rightarrow -1} [4t(t + 1)]^{2/3} &= \left[\lim_{t \rightarrow -1} 4t(t + 1) \right]^{2/3} = \left[\lim_{t \rightarrow -1} (4t) \cdot \lim_{t \rightarrow -1} (t + 1) \right]^{2/3} \\ &= \left[4 \lim_{t \rightarrow -1} t \cdot \left(\lim_{t \rightarrow -1} t + \lim_{t \rightarrow -1} 1 \right) \right]^{2/3} = [4(-1)(-1 + 1)]^{2/3} = 0^{2/3} = \boxed{0}. \end{aligned}$$

$$26. \lim_{x \rightarrow 0} (x^2 - 2x)^{3/5} = \left[\lim_{x \rightarrow 0} (x^2 - 2x) \right]^{3/5} = \left[\left(\lim_{x \rightarrow 0} x \right)^2 - 2 \lim_{x \rightarrow 0} x \right]^{3/5} = (0^2 - 2(0))^{3/5} = 0^{3/5} = \boxed{0}.$$

$$27. \lim_{t \rightarrow 1} (3t^2 - 2t + 4) = 3(1)^2 - 2(1) + 4 = \boxed{5}.$$

$$28. \lim_{x \rightarrow 0} (-3x^4 + 2x + 1) = -3(0)^4 + 2(0) + 1 = \boxed{1}.$$

$$29. \lim_{x \rightarrow \frac{1}{2}} (2x^4 - 8x^3 + 4x - 5) = 2 \left(\frac{1}{2} \right)^4 - 8 \left(\frac{1}{2} \right)^3 + 4 \left(\frac{1}{2} \right) - 5 = \frac{1}{8} - 1 + 2 - 5 = \boxed{-\frac{31}{8}}.$$

$$30. \lim_{x \rightarrow -\frac{1}{3}} (27x^3 + 9x + 1) = 27 \left(-\frac{1}{3} \right)^3 + 9 \left(-\frac{1}{3} \right) + 1 = -1 - 3 + 1 = \boxed{-3}.$$

31. Because the limit of the denominator $\lim_{x \rightarrow 4} \sqrt{x} = \sqrt{4} = 2 \neq 0$,

$$\lim_{x \rightarrow 4} \frac{x^2 + 4}{\sqrt{x}} = \frac{\lim_{x \rightarrow 4} (x^2 + 4)}{\lim_{x \rightarrow 4} \sqrt{x}} = \frac{4^2 + 4}{\sqrt{\lim_{x \rightarrow 4} x}} = \frac{20}{\sqrt{4}} = \frac{20}{2} = \boxed{10}.$$

32. Because the limit of the denominator $\lim_{x \rightarrow 3} \sqrt{3x} = \sqrt{9} = 3 \neq 0$,

$$\lim_{x \rightarrow 3} \frac{x^2 + 5}{\sqrt{3x}} = \frac{\lim_{x \rightarrow 3} (x^2 + 5)}{\lim_{x \rightarrow 3} \sqrt{3x}} = \frac{3^2 + 5}{\sqrt{\lim_{x \rightarrow 3} 3x}} = \frac{14}{\sqrt{9}} = \boxed{\frac{14}{3}}.$$

33. Because $x = -2$ is in the domain of the rational function $R(x) = \frac{2x^3 + 5x}{3x - 2}$,

$$\lim_{x \rightarrow -2} R(x) = R(-2) = \frac{2(-2)^3 + 5(-2)}{3(-2) - 2} = \frac{-26}{-8} = \boxed{\frac{13}{4}}.$$

34. Because $x = 1$ is in the domain of the rational function $R(x) = \frac{2x^4 - 1}{3x^3 + 2}$,

$$\lim_{x \rightarrow 1} R(x) = R(1) = \frac{2(1)^4 - 1}{3(1)^3 + 2} = \boxed{\frac{1}{5}}.$$

35. Observe that the limit of the denominator is equal to zero. Factoring the numerator and simplifying yields

$$\lim_{x \rightarrow 2} \frac{x^2 - 4}{x - 2} = \lim_{x \rightarrow 2} \frac{(x - 2)(x + 2)}{x - 2} = \lim_{x \rightarrow 2} (x + 2) = \boxed{4}.$$

36. Observe that the limit of the denominator is equal to zero. Factoring the denominator and simplifying yields

$$\lim_{x \rightarrow -2} \frac{x + 2}{x^2 - 4} = \lim_{x \rightarrow -2} \frac{x + 2}{(x - 2)(x + 2)} = \lim_{x \rightarrow -2} \frac{1}{x - 2} = \boxed{-\frac{1}{4}}.$$

37. Observe that the limit of the denominator is equal to zero. Factoring the numerator and simplifying yields

$$\lim_{x \rightarrow -1} \frac{x^3 - x}{x + 1} = \lim_{x \rightarrow -1} \frac{x(x - 1)(x + 1)}{x + 1} = \lim_{x \rightarrow -1} [x(x - 1)] = (-1)(-2) = \boxed{2}.$$

38. Observe that the limit of the denominator is equal to zero. Factoring both the numerator and the denominator and simplifying yields

$$\lim_{x \rightarrow -1} \frac{x^3 + x^2}{x^2 - 1} = \lim_{x \rightarrow -1} \frac{x^2(x + 1)}{(x - 1)(x + 1)} = \lim_{x \rightarrow -1} \frac{x^2}{x - 1} = \frac{(-1)^2}{-2} = \boxed{-\frac{1}{2}}.$$

39. Observe that

$$\frac{2x}{x+8} + \frac{16}{x+8} = \frac{2x+16}{x+8} = \frac{2(x+8)}{x+8} = 2,$$

provided that $x \neq -8$. Therefore,

$$\lim_{x \rightarrow -8} \left(\frac{2x}{x+8} + \frac{16}{x+8} \right) = \lim_{x \rightarrow -8} 2 = \boxed{2}.$$

40. Observe that

$$\frac{3x}{x-2} - \frac{6}{x-2} = \frac{3x-6}{x-2} = \frac{3(x-2)}{x-2} = 3,$$

provided that $x \neq 2$. Therefore,

$$\lim_{x \rightarrow 2} \left(\frac{3x}{x-2} - \frac{6}{x-2} \right) = \lim_{x \rightarrow 2} 3 = \boxed{3}.$$

41. Observe that the limit of the denominator is equal to zero. Multiplying numerator and denominator by $\sqrt{x} + \sqrt{2}$, the conjugate of $\sqrt{x} - \sqrt{2}$, yields

$$\begin{aligned} \lim_{x \rightarrow 2} \frac{\sqrt{x} - \sqrt{2}}{x - 2} &= \lim_{x \rightarrow 2} \frac{\sqrt{x} - \sqrt{2}}{x - 2} \cdot \frac{\sqrt{x} + \sqrt{2}}{\sqrt{x} + \sqrt{2}} = \lim_{x \rightarrow 2} \frac{x - 2}{(x - 2)(\sqrt{x} + \sqrt{2})} \\ &= \lim_{x \rightarrow 2} \frac{1}{\sqrt{x} + \sqrt{2}} = \frac{1}{\sqrt{2} + \sqrt{2}} = \boxed{\frac{1}{2\sqrt{2}}}. \end{aligned}$$

42. Observe that the limit of the denominator is equal to zero. Multiplying numerator and denominator by $\sqrt{x} + \sqrt{3}$, the conjugate of $\sqrt{x} - \sqrt{3}$, yields

$$\begin{aligned} \lim_{x \rightarrow 3} \frac{\sqrt{x} - \sqrt{3}}{x - 3} &= \lim_{x \rightarrow 3} \frac{\sqrt{x} - \sqrt{3}}{x - 3} \cdot \frac{\sqrt{x} + \sqrt{3}}{\sqrt{x} + \sqrt{3}} = \lim_{x \rightarrow 3} \frac{x - 3}{(x - 3)(\sqrt{x} + \sqrt{3})} \\ &= \lim_{x \rightarrow 3} \frac{1}{\sqrt{x} + \sqrt{3}} = \frac{1}{\sqrt{3} + \sqrt{3}} = \boxed{\frac{1}{2\sqrt{3}}}. \end{aligned}$$

43. Observe that the limit of the denominator is equal to zero. Multiplying numerator and denominator by $\sqrt{x+5} + 3$, the conjugate of $\sqrt{x+5} - 3$, yields

$$\begin{aligned} \lim_{x \rightarrow 4} \frac{\sqrt{x+5} - 3}{(x-4)(x+1)} &= \lim_{x \rightarrow 4} \frac{\sqrt{x+5} - 3}{(x-4)(x+1)} \cdot \frac{\sqrt{x+5} + 3}{\sqrt{x+5} + 3} = \lim_{x \rightarrow 4} \frac{(x+5) - 9}{(x-4)(x+1)(\sqrt{x+5} + 3)} \\ &= \lim_{x \rightarrow 4} \frac{x - 4}{(x-4)(x+1)(\sqrt{x+5} + 3)} = \lim_{x \rightarrow 4} \frac{1}{(x+1)(\sqrt{x+5} + 3)} \\ &= \frac{1}{(4+1)(\sqrt{4+5} + 3)} = \boxed{\frac{1}{30}}. \end{aligned}$$

44. Observe that the limit of the denominator is equal to zero. Multiplying numerator and denominator by $\sqrt{x+1} + 2$, the conjugate of $\sqrt{x+1} - 2$, yields

$$\begin{aligned} \lim_{x \rightarrow 3} \frac{\sqrt{x+1} - 2}{x(x-3)} &= \lim_{x \rightarrow 3} \frac{\sqrt{x+1} - 2}{x(x-3)} \cdot \frac{\sqrt{x+1} + 2}{\sqrt{x+1} + 2} = \lim_{x \rightarrow 3} \frac{(x+1) - 4}{x(x-3)(\sqrt{x+1} + 2)} \\ &= \lim_{x \rightarrow 3} \frac{x - 3}{x(x-3)(\sqrt{x+1} + 2)} = \lim_{x \rightarrow 3} \frac{1}{x(\sqrt{x+1} + 2)} = \frac{1}{3(\sqrt{3+1} + 2)} = \boxed{\frac{1}{12}}. \end{aligned}$$

45. $\lim_{x \rightarrow 3^-} (x^2 - 4) = (3)^2 - 4 = \boxed{5}.$

46. $\lim_{x \rightarrow 2^+} (3x^2 + x) = 3(2)^2 + 2 = \boxed{14}$.

47. Observe that the limit of the denominator is equal to zero. Factoring the numerator and simplifying yields

$$\lim_{x \rightarrow 3^-} \frac{x^2 - 9}{x - 3} = \lim_{x \rightarrow 3^-} \frac{(x - 3)(x + 3)}{x - 3} = \lim_{x \rightarrow 3^-} (x + 3) = 3 + 3 = \boxed{6}.$$

48. Observe that the limit of the denominator is equal to zero. Factoring the numerator and simplifying yields

$$\lim_{x \rightarrow 3^+} \frac{x^2 - 9}{x - 3} = \lim_{x \rightarrow 3^+} \frac{(x - 3)(x + 3)}{x - 3} = \lim_{x \rightarrow 3^+} (x + 3) = 3 + 3 = \boxed{6}.$$

49. $\lim_{x \rightarrow 3^-} (\sqrt{9 - x^2} + x)^2 = \left(\lim_{x \rightarrow 3^-} (\sqrt{9 - x^2} + x) \right)^2 = (\sqrt{9 - 3^2} + 3)^2 = \boxed{9}$.

50. $\lim_{x \rightarrow 2^+} (2\sqrt{x^2 - 4} + 3x) = 2\sqrt{2^2 - 4} + 3(2) = \boxed{6}$.

51. $\lim_{x \rightarrow c} [f(x) - 3g(x)] = \lim_{x \rightarrow c} f(x) - 3 \lim_{x \rightarrow c} g(x) = 5 - 3(2) = \boxed{-1}$.

52. $\lim_{x \rightarrow c} [5f(x)] = 5 \lim_{x \rightarrow c} f(x) = 5(5) = \boxed{25}$.

53. $\lim_{x \rightarrow c} [g(x)]^3 = \left[\lim_{x \rightarrow c} g(x) \right]^3 = 2^3 = \boxed{8}$.

54. Because the limit of the denominator is not equal to zero,

$$\lim_{x \rightarrow c} \frac{f(x)}{g(x) - h(x)} = \frac{\lim_{x \rightarrow c} f(x)}{\lim_{x \rightarrow c} (g(x) - h(x))} = \frac{\lim_{x \rightarrow c} f(x)}{\lim_{x \rightarrow c} g(x) - \lim_{x \rightarrow c} h(x)} = \frac{5}{2 - 0} = \boxed{\frac{5}{2}}.$$

55. Because the limit of the denominator is not equal to zero,

$$\lim_{x \rightarrow c} \frac{h(x)}{g(x)} = \frac{\lim_{x \rightarrow c} h(x)}{\lim_{x \rightarrow c} g(x)} = \frac{0}{2} = \boxed{0}.$$

56. $\lim_{x \rightarrow c} [4f(x) \cdot g(x)] = 4 \lim_{x \rightarrow c} f(x) \cdot \lim_{x \rightarrow c} g(x) = 4(5)(2) = \boxed{40}$.

57. Because the limit of the denominator is not equal to zero,

$$\lim_{x \rightarrow c} \left[\frac{1}{g(x)} \right]^2 = \left[\lim_{x \rightarrow c} \frac{1}{g(x)} \right]^2 = \left[\frac{\lim_{x \rightarrow c} 1}{\lim_{x \rightarrow c} g(x)} \right]^2 = \left[\frac{1}{2} \right]^2 = \boxed{\frac{1}{4}}.$$

58. $\lim_{x \rightarrow c} \sqrt[3]{5g(x) - 3} = \sqrt[3]{\lim_{x \rightarrow c} (5g(x) - 3)} = \sqrt[3]{5 \lim_{x \rightarrow c} g(x) - \lim_{x \rightarrow c} 3} = \sqrt[3]{5(2) - 3} = \boxed{\sqrt[3]{7}}$.

59. (a) $\lim_{x \rightarrow 4} [f(x) + g(x)] = \lim_{x \rightarrow 4} f(x) + \lim_{x \rightarrow 4} g(x) = 8 + (-2) = \boxed{6}$.

(b) $\lim_{x \rightarrow 4} \{f(x)[g(x) - h(x)]\} = \lim_{x \rightarrow 4} f(x) \left(\lim_{x \rightarrow 4} g(x) - \lim_{x \rightarrow 4} h(x) \right) = 8(-2 + 0) = \boxed{-16}$.

(c) $\lim_{x \rightarrow 4} [f(x) \cdot g(x)] = \lim_{x \rightarrow 4} f(x) \cdot \lim_{x \rightarrow 4} g(x) = 8(-2) = \boxed{-16}$.

(d) $\lim_{x \rightarrow 4} [2h(x)] = 2 \lim_{x \rightarrow 4} h(x) = 2(0) = \boxed{0}$.

(e) $\lim_{x \rightarrow 4} \frac{g(x)}{f(x)} = \frac{\lim_{x \rightarrow 4} g(x)}{\lim_{x \rightarrow 4} f(x)} = \frac{-2}{8} = \boxed{-\frac{1}{4}}$.

$$(f) \lim_{x \rightarrow 4} \frac{h(x)}{f(x)} = \frac{\lim_{x \rightarrow 4} h(x)}{\lim_{x \rightarrow 4} f(x)} = \frac{0}{8} = \boxed{0}.$$

$$60. (a) \lim_{x \rightarrow 3} \{2[f(x) + h(x)]\} = 2 \left(\lim_{x \rightarrow 3} f(x) + \lim_{x \rightarrow 3} h(x) \right) = 2(0 + (-2)) = \boxed{-4}.$$

$$(b) \lim_{x \rightarrow 3^-} [g(x) + h(x)] = \lim_{x \rightarrow 3^-} g(x) + \lim_{x \rightarrow 3^-} h(x) = 6 + (-2) = \boxed{4}.$$

$$(c) \lim_{x \rightarrow 3} \sqrt[3]{h(x)} = \sqrt[3]{\lim_{x \rightarrow 3} h(x)} = \sqrt[3]{-2} = \boxed{-\sqrt[3]{2}}.$$

$$(d) \lim_{x \rightarrow 3} \frac{f(x)}{h(x)} = \frac{\lim_{x \rightarrow 3} f(x)}{\lim_{x \rightarrow 3} h(x)} = \frac{0}{-2} = \boxed{0}.$$

$$(e) \lim_{x \rightarrow 3} [h(x)]^3 = \left(\lim_{x \rightarrow 3} h(x) \right)^3 = (-2)^3 = \boxed{-8}.$$

(f) Because

$$\lim_{x \rightarrow 3} [f(x) - 2h(x)] = \lim_{x \rightarrow 3} f(x) - 2 \lim_{x \rightarrow 3} h(x) = 0 - 2(-2) = 4,$$

it follows that

$$\lim_{x \rightarrow 3} [f(x) - 2h(x)]^{3/2} = \left[\lim_{x \rightarrow 3} (f(x) - 2h(x)) \right]^{3/2} = 4^{3/2} = \boxed{8}.$$

61. Let $f(x) = 3x^2$ and $c = 1$. Then

$$\begin{aligned} \lim_{x \rightarrow c} \frac{f(x) - f(c)}{x - c} &= \lim_{x \rightarrow 1} \frac{f(x) - f(1)}{x - 1} = \lim_{x \rightarrow 1} \frac{3x^2 - 3}{x - 1} = \lim_{x \rightarrow 1} \frac{3(x - 1)(x + 1)}{x - 1} \\ &= \lim_{x \rightarrow 1} 3(x + 1) = 3(1 + 1) = \boxed{6}. \end{aligned}$$

62. Let $f(x) = 8x^3$ and $c = 2$. Then

$$\begin{aligned} \lim_{x \rightarrow c} \frac{f(x) - f(c)}{x - c} &= \lim_{x \rightarrow 2} \frac{f(x) - f(2)}{x - 2} = \lim_{x \rightarrow 2} \frac{8x^3 - 64}{x - 2} = \lim_{x \rightarrow 2} \frac{8(x - 2)(x^2 + 2x + 4)}{x - 2} \\ &= 8 \lim_{x \rightarrow 2} (x^2 + 2x + 4) = 8(2^2 + 2(2) + 4) = \boxed{96}. \end{aligned}$$

63. Let $f(x) = -2x^2 + 4$ and $c = 1$. Then

$$\begin{aligned} \lim_{x \rightarrow c} \frac{f(x) - f(c)}{x - c} &= \lim_{x \rightarrow 1} \frac{f(x) - f(1)}{x - 1} = \lim_{x \rightarrow 1} \frac{-2x^2 + 4 - 2}{x - 1} = \lim_{x \rightarrow 1} \frac{-2x^2 + 2}{x - 1} \\ &= \lim_{x \rightarrow 1} \frac{-2(x - 1)(x + 1)}{x - 1} = -2 \lim_{x \rightarrow 1} (x + 1) = -2(1 + 1) = \boxed{-4}. \end{aligned}$$

64. Let $f(x) = 20 - 0.8x^2$ and $c = 3$. Then

$$\begin{aligned} \lim_{x \rightarrow c} \frac{f(x) - f(c)}{x - c} &= \lim_{x \rightarrow 3} \frac{f(x) - f(3)}{x - 3} = \lim_{x \rightarrow 3} \frac{20 - 0.8x^2 - 12.8}{x - 3} = \lim_{x \rightarrow 3} \frac{-0.8x^2 + 7.2}{x - 3} \\ &= \lim_{x \rightarrow 3} \frac{-0.8(x - 3)(x + 3)}{x - 3} = -0.8 \lim_{x \rightarrow 3} (x + 3) = -0.8(3 + 3) = \boxed{-4.8}. \end{aligned}$$

65. Let $f(x) = \sqrt{x}$ and $c = 1$. Then

$$\begin{aligned} \lim_{x \rightarrow c} \frac{f(x) - f(c)}{x - c} &= \lim_{x \rightarrow 1} \frac{f(x) - f(1)}{x - 1} = \lim_{x \rightarrow 1} \frac{\sqrt{x} - 1}{x - 1} = \lim_{x \rightarrow 1} \frac{\sqrt{x} - 1}{x - 1} \cdot \frac{\sqrt{x} + 1}{\sqrt{x} + 1} \\ &= \lim_{x \rightarrow 1} \frac{x - 1}{(x - 1)(\sqrt{x} + 1)} = \lim_{x \rightarrow 1} \frac{1}{\sqrt{x} + 1} = \frac{1}{1 + 1} = \boxed{\frac{1}{2}}. \end{aligned}$$

66. Let $f(x) = \sqrt{2x}$ and $c = 5$. Then

$$\begin{aligned}\lim_{x \rightarrow c} \frac{f(x) - f(c)}{x - c} &= \lim_{x \rightarrow 5} \frac{f(x) - f(5)}{x - 5} = \lim_{x \rightarrow 5} \frac{\sqrt{2x} - \sqrt{10}}{x - 5} = \lim_{x \rightarrow 5} \frac{\sqrt{2x} - \sqrt{10}}{x - 5} \cdot \frac{\sqrt{2x} + \sqrt{10}}{\sqrt{2x} + \sqrt{10}} \\ &= \lim_{x \rightarrow 5} \frac{2x - 10}{(x - 5)(\sqrt{2x} + \sqrt{10})} = \lim_{x \rightarrow 5} \frac{2}{\sqrt{2x} + \sqrt{10}} = \frac{2}{\sqrt{10} + \sqrt{10}} = \boxed{\frac{1}{\sqrt{10}}}.\end{aligned}$$

67. Let $f(x) = 4x - 3$. Then

$$\begin{aligned}\lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} &= \lim_{h \rightarrow 0} \frac{4(x+h) - 3 - (4x - 3)}{h} = \lim_{h \rightarrow 0} \frac{4x + 4h - 3 - 4x + 3}{h} \\ &= \lim_{h \rightarrow 0} \frac{4h}{h} = \lim_{h \rightarrow 0} 4 = \boxed{4}.\end{aligned}$$

68. Let $f(x) = 3x + 5$. Then

$$\begin{aligned}\lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} &= \lim_{h \rightarrow 0} \frac{3(x+h) + 5 - (3x + 5)}{h} = \lim_{h \rightarrow 0} \frac{3x + 3h + 5 - 3x - 5}{h} \\ &= \lim_{h \rightarrow 0} \frac{3h}{h} = \lim_{h \rightarrow 0} 3 = \boxed{3}.\end{aligned}$$

69. Let $f(x) = 3x^2 + 4x + 1$. Then

$$\begin{aligned}\lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} &= \lim_{h \rightarrow 0} \frac{3(x+h)^2 + 4(x+h) + 1 - (3x^2 + 4x + 1)}{h} \\ &= \lim_{h \rightarrow 0} \frac{3x^2 + 6xh + 3h^2 + 4x + 4h + 1 - 3x^2 - 4x - 1}{h} \\ &= \lim_{h \rightarrow 0} \frac{6xh + 3h^2 + 4h}{h} = \lim_{h \rightarrow 0} (6x + 3h + 4) = 6x + 3(0) + 4 = \boxed{6x + 4}.\end{aligned}$$

70. Let $f(x) = 2x^2 + x$. Then

$$\begin{aligned}\lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} &= \lim_{h \rightarrow 0} \frac{2(x+h)^2 + (x+h) - (2x^2 + x)}{h} \\ &= \lim_{h \rightarrow 0} \frac{2x^2 + 4xh + 2h^2 + x + h - 2x^2 - x}{h} \\ &= \lim_{h \rightarrow 0} \frac{4xh + 2h^2 + h}{h} = \lim_{h \rightarrow 0} (4x + 2h + 1) = 4x + 2(0) + 1 = \boxed{4x + 1}.\end{aligned}$$

71. Let $f(x) = \frac{2}{x}$. Then

$$\begin{aligned}\lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} &= \lim_{h \rightarrow 0} \frac{\frac{2}{x+h} - \frac{2}{x}}{h} = \lim_{h \rightarrow 0} \frac{\frac{2}{x+h} - \frac{2}{x}}{h} \cdot \frac{x(x+h)}{x(x+h)} = \lim_{h \rightarrow 0} \frac{2x - 2(x+h)}{hx(x+h)} \\ &= \lim_{h \rightarrow 0} \frac{-2h}{hx(x+h)} = -\lim_{h \rightarrow 0} \frac{2}{x(x+h)} = -\frac{2}{x(x+0)} = \boxed{-\frac{2}{x^2}}.\end{aligned}$$

72. Let $f(x) = \frac{3}{x^2}$. Then

$$\begin{aligned}\lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} &= \lim_{h \rightarrow 0} \frac{\frac{3}{(x+h)^2} - \frac{3}{x^2}}{h} = \lim_{h \rightarrow 0} \frac{\frac{3}{(x+h)^2} - \frac{3}{x^2}}{h} \cdot \frac{x^2(x+h)^2}{x^2(x+h)^2} \\ &= \lim_{h \rightarrow 0} \frac{3x^2 - 3(x+h)^2}{hx^2(x+h)^2} = \lim_{h \rightarrow 0} \frac{3x^2 - 3x^2 - 6xh - 3h^2}{hx^2(x+h)^2} \\ &= -\lim_{h \rightarrow 0} \frac{h(6x + 3h)}{hx^2(x+h)^2} = -\lim_{h \rightarrow 0} \frac{6x + 3h}{x^2(x+h)^2} = -\frac{6x + 3(0)}{x^2(x+0)^2} = -\frac{6x}{x^4} = \boxed{-\frac{6}{x^3}}.\end{aligned}$$

73. For $x < 1$, $f(x) = 2x - 3$, so that

$$\lim_{x \rightarrow 1^-} f(x) = \lim_{x \rightarrow 1^-} (2x - 3) = 2(1) - 3 = \boxed{-1},$$

while for $x > 1$, $f(x) = 3 - x$, so that

$$\lim_{x \rightarrow 1^+} f(x) = \lim_{x \rightarrow 1^+} (3 - x) = 3 - 1 = \boxed{2}.$$

Because the two one-sided limits as x approaches 1 are not equal, $\boxed{\lim_{x \rightarrow 1} f(x) \text{ does not exist}}.$

74. For $x < 2$, $f(x) = 5x + 2$, so that

$$\lim_{x \rightarrow 2^-} f(x) = \lim_{x \rightarrow 2^-} (5x + 2) = 5(2) + 2 = \boxed{12},$$

while for $x > 2$, $f(x) = 1 + 3x$, so that

$$\lim_{x \rightarrow 2^+} f(x) = \lim_{x \rightarrow 2^+} (1 + 3x) = 1 + 3(2) = \boxed{7}.$$

Because the two one-sided limits as x approaches 2 are not equal, $\boxed{\lim_{x \rightarrow 2} f(x) \text{ does not exist}}.$

75. For $x < 1$, $f(x) = 3x - 1$, so that

$$\lim_{x \rightarrow 1^-} f(x) = \lim_{x \rightarrow 1^-} (3x - 1) = 3(1) - 1 = \boxed{2},$$

while for $x > 1$, $f(x) = 2x$, so that

$$\lim_{x \rightarrow 1^+} f(x) = \lim_{x \rightarrow 1^+} 2x = 2(1) = \boxed{2}.$$

Because the two one-sided limits as x approaches 1 are equal to 2, $\boxed{\lim_{x \rightarrow 1} f(x) = 2}.$

76. For $x < 1$, $f(x) = 3x - 1$, so that

$$\lim_{x \rightarrow 1^-} f(x) = \lim_{x \rightarrow 1^-} (3x - 1) = 3(1) - 1 = \boxed{2},$$

while for $x > 1$, $f(x) = 2x$, so that

$$\lim_{x \rightarrow 1^+} f(x) = \lim_{x \rightarrow 1^+} 2x = 2(1) = \boxed{2}.$$

Because the two one-sided limits as x approaches 1 are equal to 2, $\boxed{\lim_{x \rightarrow 1} f(x) = 2}.$

77. For $x < 1$, $f(x) = x - 1$, so that

$$\lim_{x \rightarrow 1^-} f(x) = \lim_{x \rightarrow 1^-} (x - 1) = 1 - 1 = \boxed{0},$$

while for $x > 1$, $f(x) = \sqrt{x - 1}$, so that

$$\lim_{x \rightarrow 1^+} f(x) = \lim_{x \rightarrow 1^+} \sqrt{x - 1} = \sqrt{1 - 1} = \boxed{0}.$$

Because the two one-sided limits as x approaches 1 are equal to 0, $\boxed{\lim_{x \rightarrow 1} f(x) = 0}.$

78. For $x < 3$, $f(x) = \sqrt{9 - x^2}$, so that

$$\lim_{x \rightarrow 3^-} f(x) = \lim_{x \rightarrow 3^-} \sqrt{9 - x^2} = \sqrt{9 - 3^2} = \boxed{0},$$

while for $x > 3$, $f(x) = \sqrt{x^2 - 9}$, so that

$$\lim_{x \rightarrow 3^+} f(x) = \lim_{x \rightarrow 3^+} \sqrt{x^2 - 9} = \sqrt{3^2 - 9} = \boxed{0}.$$

Because the two one-sided limits as x approaches 3 are equal to 0, $\boxed{\lim_{x \rightarrow 3} f(x) = 0}$.

79. For $x \neq 3$, $f(x) = \frac{x^2 - 9}{x - 3}$, so that

$$\lim_{x \rightarrow 3^-} f(x) = \lim_{x \rightarrow 3^-} \frac{x^2 - 9}{x - 3} = \lim_{x \rightarrow 3^-} \frac{(x + 3)(x - 3)}{x - 3} = \lim_{x \rightarrow 3^-} (x + 3) = 3 + 3 = \boxed{6},$$

and

$$\lim_{x \rightarrow 3^+} f(x) = \lim_{x \rightarrow 3^+} \frac{x^2 - 9}{x - 3} = \lim_{x \rightarrow 3^+} \frac{(x + 3)(x - 3)}{x - 3} = \lim_{x \rightarrow 3^+} (x + 3) = 3 + 3 = \boxed{6}.$$

Because the two one-sided limits as x approaches 3 are equal to 6, $\boxed{\lim_{x \rightarrow 3} f(x) = 6}$.

80. For $x \neq 2$, $f(x) = \frac{x - 2}{x^2 - 4}$, so that

$$\lim_{x \rightarrow 2^-} f(x) = \lim_{x \rightarrow 2^-} \frac{x - 2}{x^2 - 4} = \lim_{x \rightarrow 2^-} \frac{x - 2}{(x - 2)(x + 2)} = \lim_{x \rightarrow 2^-} \frac{1}{x + 2} = \frac{1}{2 + 2} = \boxed{\frac{1}{4}},$$

and

$$\lim_{x \rightarrow 2^+} f(x) = \lim_{x \rightarrow 2^+} \frac{x - 2}{x^2 - 4} = \lim_{x \rightarrow 2^+} \frac{x - 2}{(x - 2)(x + 2)} = \lim_{x \rightarrow 2^+} \frac{1}{x + 2} = \frac{1}{2 + 2} = \boxed{\frac{1}{4}}.$$

Because the two one-sided limits as x approaches 2 are equal to $\frac{1}{4}$, $\boxed{\lim_{x \rightarrow 2} f(x) = \frac{1}{4}}$.

Applications and Extensions

81. For $t < 1$,

$$\lim_{t \rightarrow 1^-} u_1(t) = \lim_{t \rightarrow 1^-} 0 = 0,$$

while for $t > 1$,

$$\lim_{t \rightarrow 1^+} u_1(t) = \lim_{t \rightarrow 1^+} 1 = 1.$$

Because the two one-sided limits as x approaches 1 are not equal, $\boxed{\lim_{t \rightarrow 1} u_1(t) \text{ does not exist}}$.

82. For $t < 3$,

$$\lim_{t \rightarrow 3^-} u_3(t) = \lim_{t \rightarrow 3^-} 0 = 0,$$

while for $t > 3$,

$$\lim_{t \rightarrow 3^+} u_3(t) = \lim_{t \rightarrow 3^+} 1 = 1.$$

Because the two one-sided limits as x approaches 3 are not equal, $\boxed{\lim_{t \rightarrow 3} u_3(t) \text{ does not exist}}$.

$$83. \lim_{h \rightarrow 0} \frac{(x + h)^2 - x^2}{h} = \lim_{h \rightarrow 0} \frac{x^2 + 2xh + h^2 - x^2}{h} = \lim_{h \rightarrow 0} \frac{h(2x + h)}{h} = \lim_{h \rightarrow 0} (2x + h) = \boxed{2x}.$$

84.

$$\begin{aligned}\lim_{h \rightarrow 0} \frac{\sqrt{x+h} - \sqrt{x}}{h} &= \lim_{h \rightarrow 0} \frac{\sqrt{x+h} - \sqrt{x}}{h} \cdot \frac{\sqrt{x+h} + \sqrt{x}}{\sqrt{x+h} + \sqrt{x}} = \lim_{h \rightarrow 0} \frac{(x+h) - x}{h(\sqrt{x+h} + \sqrt{x})} \\ &= \lim_{h \rightarrow 0} \frac{h}{h(\sqrt{x+h} + \sqrt{x})} = \lim_{h \rightarrow 0} \frac{1}{\sqrt{x+h} + \sqrt{x}} = \boxed{\frac{1}{2\sqrt{x}}}.\end{aligned}$$

85.

$$\begin{aligned}\lim_{h \rightarrow 0} \frac{\frac{1}{x+h} - \frac{1}{x}}{h} &= \lim_{h \rightarrow 0} \frac{\frac{1}{x+h} - \frac{1}{x}}{h} \cdot \frac{x(x+h)}{x(x+h)} = \lim_{h \rightarrow 0} \frac{x - (x+h)}{hx(x+h)} = -\lim_{h \rightarrow 0} \frac{h}{hx(x+h)} \\ &= -\lim_{h \rightarrow 0} \frac{1}{x(x+h)} = \boxed{-\frac{1}{x^2}}.\end{aligned}$$

86.

$$\begin{aligned}\lim_{h \rightarrow 0} \frac{\frac{1}{(x+h)^3} - \frac{1}{x^3}}{h} &= \lim_{h \rightarrow 0} \frac{\frac{1}{(x+h)^3} - \frac{1}{x^3}}{h} \cdot \frac{x^3(x+h)^3}{x^3(x+h)^3} = \lim_{h \rightarrow 0} \frac{x^3 - (x+h)^3}{hx^3(x+h)^3} \\ &= \lim_{h \rightarrow 0} \frac{x^3 - x^3 - 3x^2h - 3xh^2 - h^3}{hx^3(x+h)^3} = -\lim_{h \rightarrow 0} \frac{h(3x^2 + 3xh + h^2)}{hx^3(x+h)^3} \\ &= -\lim_{h \rightarrow 0} \frac{3x^2 + 3xh + h^2}{x^3(x+h)^3} = -\frac{3x^2}{x^6} = \boxed{-\frac{3}{x^4}}.\end{aligned}$$

87. Observe that

$$\frac{1}{4+x} - \frac{1}{4} = \frac{4 - (4+x)}{4(4+x)} = -\frac{x}{4(4+x)},$$

so that

$$\lim_{x \rightarrow 0} \left[\frac{1}{x} \left(\frac{1}{4+x} - \frac{1}{4} \right) \right] = \lim_{x \rightarrow 0} \left[\frac{1}{x} \left(-\frac{x}{4(4+x)} \right) \right] = -\lim_{x \rightarrow 0} \frac{1}{4(4+x)} = \boxed{-\frac{1}{16}}.$$

88. Observe that

$$\frac{1}{3} - \frac{1}{x+4} = \frac{(x+4) - 3}{3(x+4)} = \frac{x+1}{3(x+4)},$$

so that

$$\lim_{x \rightarrow -1} \left[\frac{2}{x+1} \left(\frac{1}{3} - \frac{1}{x+4} \right) \right] = \lim_{x \rightarrow -1} \left[\frac{2}{x+1} \left(\frac{x+1}{3(x+4)} \right) \right] = \lim_{x \rightarrow -1} \frac{2}{3(x+4)} = \boxed{\frac{2}{9}}.$$

89.

$$\begin{aligned}\lim_{x \rightarrow 7} \frac{x-7}{\sqrt{x+2}-3} &= \lim_{x \rightarrow 7} \frac{x-7}{\sqrt{x+2}-3} \cdot \frac{\sqrt{x+2}+3}{\sqrt{x+2}+3} = \lim_{x \rightarrow 7} \frac{(x-7)(\sqrt{x+2}+3)}{(x+2)-9} \\ &= \lim_{x \rightarrow 7} \frac{(x-7)(\sqrt{x+2}+3)}{x-7} = \lim_{x \rightarrow 7} (\sqrt{x+2}+3) = \sqrt{9}+3 = \boxed{6}.\end{aligned}$$

90.

$$\begin{aligned}\lim_{x \rightarrow 2} \frac{x-2}{\sqrt{x+2}-2} &= \lim_{x \rightarrow 2} \frac{x-2}{\sqrt{x+2}-2} \cdot \frac{\sqrt{x+2}+2}{\sqrt{x+2}+2} = \lim_{x \rightarrow 2} \frac{(x-2)(\sqrt{x+2}+2)}{(x+2)-4} \\ &= \lim_{x \rightarrow 2} \frac{(x-2)(\sqrt{x+2}+2)}{x-2} = \lim_{x \rightarrow 2} (\sqrt{x+2}+2) = \sqrt{4}+2 = \boxed{4}.\end{aligned}$$

$$91. \lim_{x \rightarrow 1} \frac{x^3 - 3x^2 + 3x - 1}{x^2 - 2x + 1} = \lim_{x \rightarrow 1} \frac{(x-1)^3}{(x-1)^2} = \lim_{x \rightarrow 1} (x-1) = 1 - 1 = \boxed{0}.$$

$$92. \lim_{x \rightarrow -3} \frac{x^3 + 7x^2 + 15x + 9}{x^2 + 6x + 9} = \lim_{x \rightarrow -3} \frac{(x+1)(x^2 + 6x + 9)}{x^2 + 6x + 9} = \lim_{x \rightarrow -3} (x+1) = -3 + 1 = \boxed{-2}.$$

93. (a) Using the rate schedule provided,

$$C(x) = \begin{cases} 9.00, & \text{if } 0 \leq x \leq 10 \\ 9.00 + 0.95(x - 10), & \text{if } 10 < x \leq 30 \\ 28.00 + 1.65(x - 30), & \text{if } 30 < x \leq 100 \\ 143.50 + 2.20(x - 100), & \text{if } x > 100. \end{cases}$$

(b) The domain of C is the set $\{x | x \geq 0\}$.

(c) Start with the one-sided limits:

$$\begin{aligned} \lim_{x \rightarrow 5^-} C(x) &= \lim_{x \rightarrow 5^-} 9.00 = 9.00 \\ \lim_{x \rightarrow 5^+} C(x) &= \lim_{x \rightarrow 5^+} 9.00 = 9.00 \\ \lim_{x \rightarrow 10^-} C(x) &= \lim_{x \rightarrow 10^-} 9.00 = 9.00 \\ \lim_{x \rightarrow 10^+} C(x) &= \lim_{x \rightarrow 10^+} [9.00 + 0.95(x - 10)] = 9.00 + 0.95(10 - 10) = 9.00 \\ \lim_{x \rightarrow 30^-} C(x) &= \lim_{x \rightarrow 30^-} [9.00 + 0.95(x - 10)] = 9.00 + 0.95(30 - 10) = 28.00 \\ \lim_{x \rightarrow 30^+} C(x) &= \lim_{x \rightarrow 30^+} [28.00 + 1.65(x - 30)] = 28.00 + 1.65(30 - 30) = 28.00 \\ \lim_{x \rightarrow 100^-} C(x) &= \lim_{x \rightarrow 100^-} [28.00 + 1.65(x - 30)] = 28.00 + 1.65(100 - 30) = 143.50 \\ \lim_{x \rightarrow 100^+} C(x) &= \lim_{x \rightarrow 100^+} [143.50 + 2.20(x - 100)] = 143.50 + 2.20(100 - 100) = 143.50 \end{aligned}$$

Based on these one-sided limits, it follows that

$$\boxed{\lim_{x \rightarrow 5} C(x) = 9.00, \quad \lim_{x \rightarrow 10} C(x) = 9.00, \quad \lim_{x \rightarrow 30} C(x) = 28.00, \quad \text{and} \quad \lim_{x \rightarrow 100} C(x) = 143.50}.$$

$$(d) \lim_{x \rightarrow 0^+} C(x) = \lim_{x \rightarrow 0^+} 9.00 = \boxed{9.00}.$$

(e) The graph of C is shown below.

94. (a) Let x denote the monthly usage of natural gas, measured in therms, and let $C(x)$ denote the monthly cost. If $x \leq 50$, the cost consists of the monthly customer charge of \$22.13, the distribution charge of \$0.25963 per therm, and the gas charge of \$0.3631 per therm. Thus,

$$C(x) = 22.13 + 0.25963x + 0.3631x = 22.13 + 0.62273x.$$

On the other hand, if $x > 50$, the cost consists of the monthly customer charge of \$22.13, a charge of \$12.98 for the first 50 therms, the distribution charge of \$0.11806 for each therm over 50, and the gas charge of \$0.3631 per therm. Thus,

$$C(x) = 22.13 + 12.98 + 0.11806(x - 50) + 0.3631x = 29.207 + 0.48116x.$$

Bringing these two pieces together, the complete cost function is

$$C(x) = \begin{cases} 22.13 + 0.62273x, & \text{if } 0 \leq x \leq 50 \\ 29.207 + 0.48116x, & \text{if } x > 50. \end{cases}$$

- (b) The domain of C is the set $\{x|x \geq 0\}$.

- (c) Start with the one-sided limits:

$$\lim_{x \rightarrow 50^-} C(x) = \lim_{x \rightarrow 50^-} (22.13 + 0.62273x) = 53.2665,$$

and

$$\lim_{x \rightarrow 50^+} C(x) = \lim_{x \rightarrow 50^+} (29.207 + 0.48116x) = 53.265.$$

From a purely mathematical standpoint, because the two one-sided limits as x approaches 50 are not equal, $\lim_{x \rightarrow 50} C(x)$ does not exist. However, from the practical cost standpoint, the two one-sided limits correspond to the same cost (\$53.27); so, in this sense, $\lim_{x \rightarrow 50} C(x)$ does exist.

- (d) $\lim_{x \rightarrow 0^+} C(x) = \lim_{x \rightarrow 0^+} (22.13 + 0.62273x) = 22.13$.

- (e) The graph of C is shown below.

95. (a) Solving the equation $\frac{1}{2}mv^2 = \frac{3}{2}kT$ for $v(T)$ yields $v(T) = \sqrt{\frac{3kT}{m}}$. Thus

$$\lim_{T \rightarrow 0} v(T) = \lim_{T \rightarrow 0} \sqrt{\frac{3kT}{m}} = \sqrt{\frac{3k}{m}} \sqrt{\lim_{T \rightarrow 0} T} = 0.$$

- (b) Answers will vary. One interpretation is that as the temperature of a gas approaches absolute zero, the average speed of the molecules in the gas also approaches zero. In other words, the molecules in the gas stop moving.

96. (a) For $h < 0$, $2 + h < 2$, so that $f(2 + h) = 3(2 + h) + 5 = 3h + 11$. Thus,

$$\lim_{h \rightarrow 0^-} \frac{f(2 + h) - f(2)}{h} = \lim_{h \rightarrow 0^-} \frac{3h + 11 - 11}{h} = \lim_{h \rightarrow 0^-} \frac{3h}{h} = \lim_{h \rightarrow 0^-} 3 = \boxed{3}.$$

- (b) For $h > 0$, $2 + h > 2$, so that $f(2 + h) = 13 - (2 + h) = 11 - h$. Thus,

$$\lim_{h \rightarrow 0^+} \frac{f(2 + h) - f(2)}{h} = \lim_{h \rightarrow 0^+} \frac{11 - h - 11}{h} = \lim_{h \rightarrow 0^+} \frac{-h}{h} = \lim_{h \rightarrow 0^+} -1 = \boxed{-1}.$$

- (c) Because the two one-sided limits as h approaches 0 are not equal, $\lim_{h \rightarrow 0} \frac{f(2 + h) - f(2)}{h}$
does not exist.

97. Consider the one-sided limits:

$$\lim_{x \rightarrow 0^-} |x| = \lim_{x \rightarrow 0^-} (-x) = 0$$

and

$$\lim_{x \rightarrow 0^+} |x| = \lim_{x \rightarrow 0^+} x = 0.$$

Because the two one-sided limits as x approaches 0 are equal to 0, $\lim_{x \rightarrow 0} |x| = 0$.

98. $\lim_{x \rightarrow 0} |x| = \lim_{x \rightarrow 0} \sqrt{x^2} = \sqrt{\lim_{x \rightarrow 0} x^2} = \sqrt{0} = 0$.

99. Answers will vary. One possibility is the following. Let

$$f(x) = \begin{cases} 1, & \text{if } x < 2 \\ 0, & \text{if } x \geq 2 \end{cases}, \quad g(x) = \begin{cases} 0, & \text{if } x < 2 \\ 1, & \text{if } x \geq 2 \end{cases},$$

and $c = 2$. Then

$$\lim_{x \rightarrow 2^-} f(x) = \lim_{x \rightarrow 2^-} 1 = 1 \text{ and } \lim_{x \rightarrow 2^+} f(x) = \lim_{x \rightarrow 2^+} 0 = 0$$

so that $\lim_{x \rightarrow 2} f(x)$ does not exist, and

$$\lim_{x \rightarrow 2^-} g(x) = \lim_{x \rightarrow 2^-} 0 = 0 \text{ and } \lim_{x \rightarrow 2^+} g(x) = \lim_{x \rightarrow 2^+} 1 = 1$$

so that $\lim_{x \rightarrow 2} g(x)$ does not exist. However, $(f + g)(x) = 1$ for all x so that $\lim_{x \rightarrow 2} [f(x) + g(x)] = 1$.

100. Answers will vary. One possibility is the following. Let

$$f(x) = \begin{cases} 1, & \text{if } x < 2 \\ 0, & \text{if } x \geq 2 \end{cases}, \quad g(x) = \begin{cases} 0, & \text{if } x < 2 \\ 1, & \text{if } x \geq 2 \end{cases},$$

and $c = 2$. Then

$$\lim_{x \rightarrow 2^-} f(x) = \lim_{x \rightarrow 2^-} 1 = 1 \text{ and } \lim_{x \rightarrow 2^+} f(x) = \lim_{x \rightarrow 2^+} 0 = 0$$

so that $\lim_{x \rightarrow 2} f(x)$ does not exist, and

$$\lim_{x \rightarrow 2^-} g(x) = \lim_{x \rightarrow 2^-} 0 = 0 \text{ and } \lim_{x \rightarrow 2^+} g(x) = \lim_{x \rightarrow 2^+} 1 = 1$$

so that $\lim_{x \rightarrow 2} g(x)$ does not exist. However, $(f \cdot g)(x) = 0$ for all x so that $\lim_{x \rightarrow 2} [f(x)g(x)] = 0$.

101. Answers will vary. One possibility is the following. Let

$$f(x) = \begin{cases} 2, & \text{if } x < 1 \\ -2, & \text{if } x \geq 1 \end{cases}, \quad g(x) = \begin{cases} 1, & \text{if } x < 1 \\ -1, & \text{if } x \geq 1 \end{cases},$$

and $c = 1$. Then

$$\lim_{x \rightarrow 1^-} f(x) = \lim_{x \rightarrow 1^-} 2 = 2 \text{ and } \lim_{x \rightarrow 1^+} f(x) = \lim_{x \rightarrow 1^+} -2 = -2$$

so that $\lim_{x \rightarrow 1} f(x)$ does not exist, and

$$\lim_{x \rightarrow 1^-} g(x) = \lim_{x \rightarrow 1^-} 1 = 1 \text{ and } \lim_{x \rightarrow 1^+} g(x) = \lim_{x \rightarrow 1^+} -1 = -1$$

so that $\lim_{x \rightarrow 1} g(x)$ does not exist. However, $\left(\frac{f}{g}\right)(x) = 2$ for all x so that $\lim_{x \rightarrow 1} \left[\frac{f(x)}{g(x)}\right] = 2$.

102. Answers will vary. One possibility is the following. Let

$$f(x) = \begin{cases} 1, & \text{if } x < 0 \\ -1, & \text{if } x \geq 0 \end{cases}$$

and $c = 0$. Then

$$\lim_{x \rightarrow 0^-} f(x) = \lim_{x \rightarrow 0^-} 1 = 1 \text{ and } \lim_{x \rightarrow 0^+} f(x) = \lim_{x \rightarrow 0^+} -1 = -1$$

so that $\lim_{x \rightarrow 0} f(x)$ does not exist. However, $|f(x)| = 1$ for all x so that $\lim_{x \rightarrow 0} |f(x)| = 1$.

103. Let $f(x) = k$, where k is any real number, and let g be a function for which $\lim_{x \rightarrow c} g(x)$ exists. Then $\lim_{x \rightarrow c} f(x)$ exists and is equal to k , so that by the Limit of a Product Theorem, $\lim_{x \rightarrow c} [f(x)g(x)]$ exists and $\lim_{x \rightarrow c} [f(x)g(x)] = \lim_{x \rightarrow c} f(x) \cdot \lim_{x \rightarrow c} g(x)$. It then follows that

$$\lim_{x \rightarrow c} [kg(x)] = \lim_{x \rightarrow c} [f(x)g(x)]$$

exists, and

$$\lim_{x \rightarrow c} [kg(x)] = \lim_{x \rightarrow c} [f(x)g(x)] = \lim_{x \rightarrow c} f(x) \cdot \lim_{x \rightarrow c} g(x) = k \lim_{x \rightarrow c} g(x).$$

104. Let c be a number in the domain of the rational function $R(x) = \frac{p(x)}{q(x)}$, where p and q are both polynomial functions. Because c is in the domain of R , $q(c) \neq 0$. Moreover, because q is a polynomial function, $\lim_{x \rightarrow c} q(x) = q(c) \neq 0$. Therefore, by the Limit of a Quotient Theorem and the Limit of a Polynomial Theorem,

$$\lim_{x \rightarrow c} R(x) = \lim_{x \rightarrow c} \frac{p(x)}{q(x)} = \frac{\lim_{x \rightarrow c} p(x)}{\lim_{x \rightarrow c} q(x)} = \frac{p(c)}{q(c)} = R(c).$$

Challenge Problems

105. When n is a positive integer,

$$x^n - a^n = (x - a)(x^{n-1} + ax^{n-2} + a^2x^{n-3} + \cdots + a^{n-2}x + a^{n-1}),$$

so that

$$\begin{aligned} \lim_{x \rightarrow a} \frac{x^n - a^n}{x - a} &= \lim_{x \rightarrow a} \frac{(x - a)(x^{n-1} + ax^{n-2} + a^2x^{n-3} + \cdots + a^{n-2}x + a^{n-1})}{x - a} \\ &= \lim_{x \rightarrow a} (x^{n-1} + ax^{n-2} + a^2x^{n-3} + \cdots + a^{n-2}x + a^{n-1}) \\ &= a^{n-1} + aa^{n-2} + a^2a^{n-3} + \cdots + a^{n-2}a + a^{n-1} = \boxed{na^{n-1}}. \end{aligned}$$

106. If n is an even positive integer, then

$$\lim_{x \rightarrow -a} (x^n + a^n) = (-a)^n + a^n = 2a^n \quad \text{and} \quad \lim_{x \rightarrow -a} (x + a) = -a + a = 0,$$

so that

$$\lim_{x \rightarrow -a} \frac{x^n + a^n}{x + a}$$

does not exist. On the other hand, if n is an odd positive integer, then

$$\begin{aligned} x^n + a^n &= (x + a)(x^{n-1} - ax^{n-2} + a^2x^{n-3} - \cdots - a^{n-2}x + a^{n-1}) \\ &= (x + a)(x^{n-1} + (-a)x^{n-2} + (-a)^2x^{n-3} + \cdots + (-a)^{n-2}x + (-a)^{n-1}), \end{aligned}$$

so that

$$\begin{aligned} \lim_{x \rightarrow -a} \frac{x^n + a^n}{x + a} &= \lim_{x \rightarrow -a} \frac{(x + a)(x^{n-1} + (-a)x^{n-2} + (-a)^2x^{n-3} + \cdots + (-a)^{n-2}x + (-a)^{n-1})}{x + a} \\ &= \lim_{x \rightarrow -a} (x^{n-1} + (-a)x^{n-2} + (-a)^2x^{n-3} + \cdots + (-a)^{n-2}x + (-a)^{n-1}) \\ &= (-a)^{n-1} + (-a)(-a)^{n-2} + (-a)^2(-a)^{n-3} + \cdots + (-a)^{n-2}(-a) + (-a)^{n-1} \\ &= n(-a)^{n-1} = \boxed{na^{n-1}}. \end{aligned}$$

107. When m and n are positive integers,

$$x^m - 1 = (x - 1)(x^{m-1} + x^{m-2} + x^{m-3} + \cdots + x + 1)$$

and

$$x^n - 1 = (x - 1)(x^{n-1} + x^{n-2} + x^{n-3} + \cdots + x + 1).$$

Thus

$$\begin{aligned} \lim_{x \rightarrow 1} \frac{x^m - 1}{x^n - 1} &= \lim_{x \rightarrow 1} \frac{(x - 1)(x^{m-1} + x^{m-2} + x^{m-3} + \cdots + x + 1)}{(x - 1)(x^{n-1} + x^{n-2} + x^{n-3} + \cdots + x + 1)} \\ &= \lim_{x \rightarrow 1} \frac{x^{m-1} + x^{m-2} + x^{m-3} + \cdots + x + 1}{x^{n-1} + x^{n-2} + x^{n-3} + \cdots + x + 1} \\ &= \frac{\overbrace{1 + 1 + 1 + \cdots + 1}^{m \text{ terms}}}{\underbrace{1 + 1 + 1 + \cdots + 1}_{n \text{ terms}}} = \boxed{\frac{m}{n}}. \end{aligned}$$

108.

$$\begin{aligned} \lim_{x \rightarrow 0} \frac{\sqrt[3]{1+x} - 1}{x} &= \lim_{x \rightarrow 0} \frac{\sqrt[3]{1+x} - 1}{x} \cdot \frac{\sqrt[3]{(1+x)^2} + \sqrt[3]{1+x} + 1}{\sqrt[3]{(1+x)^2} + \sqrt[3]{1+x} + 1} = \lim_{x \rightarrow 0} \frac{(1+x) - 1}{x(\sqrt[3]{(1+x)^2} + \sqrt[3]{1+x} + 1)} \\ &= \lim_{x \rightarrow 0} \frac{x}{x(\sqrt[3]{(1+x)^2} + \sqrt[3]{1+x} + 1)} = \lim_{x \rightarrow 0} \frac{1}{\sqrt[3]{(1+x)^2} + \sqrt[3]{1+x} + 1} \\ &= \frac{1}{\sqrt[3]{1} + \sqrt[3]{1} + 1} = \boxed{\frac{1}{3}}. \end{aligned}$$

109.

$$\begin{aligned} \lim_{x \rightarrow 0} \frac{\sqrt{(1+ax)(1+bx)} - 1}{x} &= \lim_{x \rightarrow 0} \frac{\sqrt{(1+ax)(1+bx)} - 1}{x} \cdot \frac{\sqrt{(1+ax)(1+bx)} + 1}{\sqrt{(1+ax)(1+bx)} + 1} \\ &= \lim_{x \rightarrow 0} \frac{(1+ax)(1+bx) - 1}{x(\sqrt{(1+ax)(1+bx)} + 1)} = \lim_{x \rightarrow 0} \frac{1 + (a+b)x + abx^2 - 1}{x(\sqrt{(1+ax)(1+bx)} + 1)} \\ &= \lim_{x \rightarrow 0} \frac{x[(a+b) + abx]}{x(\sqrt{(1+ax)(1+bx)} + 1)} = \lim_{x \rightarrow 0} \frac{(a+b) + abx}{\sqrt{(1+ax)(1+bx)} + 1} \\ &= \frac{a + b + ab(0)}{\sqrt{(1+0)(1+0)} + 1} = \boxed{\frac{a+b}{2}}. \end{aligned}$$

110. Note that

$$\begin{aligned}(1 + a_1x)(1 + a_2x) \cdots (1 + a_nx) &= 1 + (a_1 + a_2 + \cdots + a_n)x \\ &\quad + \text{terms containing } x^m \text{ where } m \geq 2,\end{aligned}$$

so that

$$(1 + a_1x)(1 + a_2x) \cdots (1 + a_nx) - 1 = (a_1 + a_2 + \cdots + a_n)x + \text{terms containing } x^m \text{ where } m \geq 2.$$

Thus,

$$\begin{aligned}\lim_{x \rightarrow 0} \frac{\sqrt{(1 + a_1x)(1 + a_2x) \cdots (1 + a_nx)} - 1}{x} \\&= \lim_{x \rightarrow 0} \frac{\sqrt{(1 + a_1x)(1 + a_2x) \cdots (1 + a_nx)} - 1}{x} \cdot \frac{\sqrt{(1 + a_1x)(1 + a_2x) \cdots (1 + a_nx)} + 1}{\sqrt{(1 + a_1x)(1 + a_2x) \cdots (1 + a_nx)} + 1} \\&= \lim_{x \rightarrow 0} \frac{(1 + a_1x)(1 + a_2x) \cdots (1 + a_nx) - 1}{x(\sqrt{(1 + a_1x)(1 + a_2x) \cdots (1 + a_nx)} + 1)} \\&= \lim_{x \rightarrow 0} \frac{(a_1 + a_2 + \cdots + a_n)x + \text{terms containing } x^m \text{ where } m \geq 2}{x(\sqrt{(1 + a_1x)(1 + a_2x) \cdots (1 + a_nx)} + 1)} \\&= \lim_{x \rightarrow 0} \frac{(a_1 + a_2 + \cdots + a_n) + \text{terms containing } x^m \text{ where } m \geq 1}{\sqrt{(1 + a_1x)(1 + a_2x) \cdots (1 + a_nx)} + 1} \\&= \frac{a_1 + a_2 + \cdots + a_n + 0}{\sqrt{1} + 1} = \boxed{\frac{a_1 + a_2 + \cdots + a_n}{2}}.\end{aligned}$$

111. Let $f(x) = x|x|$. For $x < 0$, $f(x) = x(-x) = -x^2$. Thus,

$$\lim_{h \rightarrow 0^-} \frac{f(h) - f(0)}{h} = \lim_{h \rightarrow 0^-} \frac{-h^2 - 0}{h} = \lim_{h \rightarrow 0^-} (-h) = 0.$$

For $x \geq 0$, $f(x) = x(x) = x^2$. Thus,

$$\lim_{h \rightarrow 0^+} \frac{f(h) - f(0)}{h} = \lim_{h \rightarrow 0^+} \frac{h^2 - 0}{h} = \lim_{h \rightarrow 0^+} h = 0.$$

Because the two one-sided limits as h approaches 0 are equal to 0,

$$\lim_{h \rightarrow 0} \frac{f(h) - f(0)}{h} = \boxed{0}.$$

1.3: Continuity

Concepts and Vocabulary

1. True. A polynomial function is continuous at every real number.
2. False. Piecewise-defined functions **may not be** continuous at numbers where the function changes equations.
3. The three conditions necessary for a function f to be continuous at a number c are $f(c)$ is defined, $\lim_{x \rightarrow c} f(x)$ exists, and $\lim_{x \rightarrow c} f(x) = f(c)$.
4. True. If $f(x)$ is continuous at 0, then $g(x) = \frac{1}{4}f(x)$ is continuous at 0.
5. False. If f is a function defined everywhere in an open interval containing c , except possibly at c , then the number c is called a removable discontinuity of f if the function f is not continuous at c but $\lim_{x \rightarrow c} f(x)$ exists.
6. False. If a function f is discontinuous at a number c , then it might be the case that $\lim_{x \rightarrow c} f(x)$ does not exist. However, the function could be discontinuous at c because $\lim_{x \rightarrow c} f(x)$ exists but either $f(c)$ is not defined or $\lim_{x \rightarrow c} f(x) \neq f(c)$.
7. False. If a function f is continuous on an open interval (a, b) , then it is continuous on the closed interval $[a, b]$ only if the function is also continuous from the right at the number a and continuous from the left at the number b .
8. True. If a function f is continuous on the closed interval $[a, b]$, then f is continuous on the open interval (a, b) .
9. This function is discontinuous. When the ball lands on the ground and stops, there will be a jump discontinuity as the velocity abruptly changes from a nonzero value to zero.
10. This function is continuous. Though the temperature might change rapidly when the oven is first turned on and then again after the oven is turned off, there will be no abrupt jumps in the temperature.
11. True. If a function f is continuous on a closed interval $[a, b]$, then the Intermediate Value Theorem guarantees that the function takes on every value y between $f(a)$ and $f(b)$.
12. False. If a function f is continuous on a closed interval $[a, b]$ and $f(a) \neq f(b)$, but both $f(a) > 0$ and $f(b) > 0$, then f **may have** a zero on the open interval (a, b) , but the Intermediate Value Theorem cannot guarantee that a zero exists. The Intermediate Value Theorem can never guarantee that a function does not have a zero on a particular interval.

Skill Building

13. (a) The function f is not continuous at $c = -3$.
 (b) Although f is defined at $c = -3$ with $f(-3) = 1$ and $\lim_{x \rightarrow -3} f(x) = -2$, $\lim_{x \rightarrow -3} f(x) \neq f(-3)$.
 (c) The discontinuity at $c = -3$ is removable because $\lim_{x \rightarrow -3} f(x)$ exists.
 (d) Redefine f at $c = -3$ so that $f(-3) = -2 = \lim_{x \rightarrow -3} f(x)$. The resulting function will then be continuous at $c = -3$.

14. (a) Because f is defined at $c = 0$ with $f(0) = 2$, $\lim_{x \rightarrow 0} f(x) = 2$, and $\lim_{x \rightarrow 0} f(x) = f(0)$, the function f is continuous at $c = 0$.
15. (a) The function f is not continuous at $c = 2$.
- (b) Although f is defined at $c = 2$ with $f(2) = 3$, $\lim_{x \rightarrow 2} f(x)$ does not exist.
- (c) The discontinuity at $c = 2$ is not removable because $\lim_{x \rightarrow 2} f(x)$ does not exist.
16. (a) The function f is not continuous at $c = 3$.
- (b) Though f is defined at $c = 3$ with $f(3) = -1$, $\lim_{x \rightarrow 3} f(x)$ does not exist.
- (c) The discontinuity at $c = 3$ is not removable because $\lim_{x \rightarrow 3} f(x)$ does not exist.
17. (a) Because f is defined at $c = 4$ with $f(4) = 0$, $\lim_{x \rightarrow 4} f(x) = 0$, and $\lim_{x \rightarrow 4} f(x) = f(4)$, the function f is continuous at $c = 4$.
18. (a) The function f is not continuous at $c = 5$.
- (b) The function f is discontinuous at $c = 5$ because f is not defined at $c = 5$ and because $\lim_{x \rightarrow 5^-} f(x) = -3$ and $\lim_{x \rightarrow 5^+} f(x) = 1$ so that $\lim_{x \rightarrow 5} f(x)$ does not exist.
- (c) The discontinuity at $c = 5$ is not removable, because $\lim_{x \rightarrow 5} f(x)$ does not exist.
19. The domain of the function $f(x) = x^2 + 1$ is the set of all real numbers, so f is defined at $c = -1$ with $f(-1) = 2$. Next,
- $$\lim_{x \rightarrow -1} f(x) = \lim_{x \rightarrow -1} (x^2 + 1) = (-1)^2 + 1 = 2,$$
- so that $\lim_{x \rightarrow -1} f(x)$ exists. Finally, $\lim_{x \rightarrow -1} f(x) = f(-1)$. Because all three conditions of the definition of continuity at $c = -1$ are satisfied, the function f is continuous at $c = -1$.
20. The domain of the function $f(x) = x^3 - 5$ is the set of all real numbers, so f is defined at $c = 5$ with $f(5) = 120$. Next,
- $$\lim_{x \rightarrow 5} f(x) = \lim_{x \rightarrow 5} (x^3 - 5) = 5^3 - 5 = 120,$$
- so that $\lim_{x \rightarrow 5} f(x)$ exists. Finally, $\lim_{x \rightarrow 5} f(x) = f(5)$. Because all three conditions of the definition of continuity at $c = 5$ are satisfied, the function f is continuous at $c = 5$.
21. Because $x^2 + 4$ is never equal to zero for any real number x , the domain of the function $f(x) = \frac{x}{x^2 + 4}$ is the set of all real numbers. Thus, f is defined at $c = -2$, with $f(-2) = -\frac{1}{4}$. Next,
- $$\lim_{x \rightarrow -2} f(x) = \lim_{x \rightarrow -2} \frac{x}{x^2 + 4} = \frac{-2}{(-2)^2 + 4} = -\frac{1}{4},$$
- so that $\lim_{x \rightarrow -2} f(x)$ exists. Finally, $\lim_{x \rightarrow -2} f(x) = f(-2)$. Because all three conditions of the definition of continuity at $c = -2$ are satisfied, the function f is continuous at $c = -2$.
22. The domain of the function $f(x) = \frac{x}{x-2}$ is the set $\{x | x \neq 2\}$. Because f is not defined at $c = 2$, the function f is not continuous at $c = 2$.

23. The domain of the function f is the set of all real numbers, so f is defined at $c = 2$ with $f(2) = 2(2) + 5 = 9$. Next,

$$\lim_{x \rightarrow 2^-} f(x) = \lim_{x \rightarrow 2^-} (2x + 5) = 9 \quad \text{and} \quad \lim_{x \rightarrow 2^+} f(x) = \lim_{x \rightarrow 2^+} (4x + 1) = 9,$$

so that $\lim_{x \rightarrow 2} f(x)$ exists and is equal to 9. Finally, $\lim_{x \rightarrow 2} f(x) = f(2)$. Because all three conditions of the definition of continuity at $c = 2$ are satisfied, the function f is continuous at $c = 2$.

24. The domain of the function f is the set of all real numbers, so f is defined at $c = 0$ with $f(0) = 2(0) + 1 = 2$. Next,

$$\lim_{x \rightarrow 0^-} f(x) = \lim_{x \rightarrow 0^-} (2x + 1) = 1 \quad \text{and} \quad \lim_{x \rightarrow 0^+} f(x) = \lim_{x \rightarrow 0^+} 2x = 0,$$

so that $\lim_{x \rightarrow 0} f(x)$ does not exist. Therefore, the function f is not continuous at $c = 0$.

25. The domain of the function f is the set of all real numbers, so f is defined at $c = 1$ with $f(1) = 4$. Next,

$$\lim_{x \rightarrow 1^-} f(x) = \lim_{x \rightarrow 1^-} (3x - 1) = 2 \quad \text{and} \quad \lim_{x \rightarrow 1^+} f(x) = \lim_{x \rightarrow 1^+} 2x = 2,$$

so that $\lim_{x \rightarrow 1} f(x)$ exists and is equal to 2. However, $\lim_{x \rightarrow 1} f(x) \neq f(1)$, so the function f is not continuous at $c = 1$.

26. The domain of the function f is the set of all real numbers, so f is defined at $c = 1$ with $f(1) = 2$. Next,

$$\lim_{x \rightarrow 1^-} f(x) = \lim_{x \rightarrow 1^-} (3x - 1) = 2 \quad \text{and} \quad \lim_{x \rightarrow 1^+} f(x) = \lim_{x \rightarrow 1^+} 2x = 2,$$

so that $\lim_{x \rightarrow 1} f(x)$ exists and is equal to 2. Finally, $\lim_{x \rightarrow 1} f(x) = f(1)$. Because all three conditions of the definition of continuity at $c = 1$ are satisfied, the function f is continuous at $c = 1$.

27. The domain of the function f is the set $\{x | x \neq 1\}$. Because f is not defined at $c = 1$, the function f is not continuous at $c = 1$.

28. The domain of the function f is the set of all real numbers, so f is defined at $c = 1$ with $f(1) = 2$. Next,

$$\lim_{x \rightarrow 1^-} f(x) = \lim_{x \rightarrow 1^-} (3x - 1) = 2 \quad \text{and} \quad \lim_{x \rightarrow 1^+} f(x) = \lim_{x \rightarrow 1^+} 3x = 3,$$

so that $\lim_{x \rightarrow 1} f(x)$ does not exist. Therefore, the function f is not continuous at $c = 1$.

29. The domain of the function f is the set of all real numbers, so f is defined at $c = 0$ with $f(0) = 0$. Next,

$$\lim_{x \rightarrow 0^-} f(x) = \lim_{x \rightarrow 0^-} x^2 = 0 \quad \text{and} \quad \lim_{x \rightarrow 0^+} f(x) = \lim_{x \rightarrow 0^+} 2x = 0,$$

so that $\lim_{x \rightarrow 0} f(x)$ exists and is equal to 0. Finally, $\lim_{x \rightarrow 0} f(x) = f(0)$. Because all three conditions of the definition of continuity at $c = 0$ are satisfied, the function f is continuous at $c = 0$.

30. The domain of the function f is the set of all real numbers, so f is defined at $c = -1$ with $f(-1) = 2$. Next,

$$\lim_{x \rightarrow -1^-} f(x) = \lim_{x \rightarrow -1^-} x^2 = 1 \quad \text{and} \quad \lim_{x \rightarrow -1^+} f(x) = \lim_{x \rightarrow -1^+} (-3x + 2) = 5,$$

so that $\lim_{x \rightarrow -1} f(x)$ does not exist. Therefore, the function f is not continuous at $c = -1$.

31. The domain of the function f is the set $\{x|x < 4\}$, so f is defined at $c = 0$ with $f(0) = 4$. Next,

$$\lim_{x \rightarrow 0^-} f(x) = \lim_{x \rightarrow 0^-} (4 - 3x^2) = 4 \quad \text{and} \quad \lim_{x \rightarrow 0^+} f(x) = \lim_{x \rightarrow 0^+} \sqrt{\frac{16 - x^2}{4 - x}} = 2,$$

so that $\lim_{x \rightarrow 0} f(x)$ does not exist. Therefore, the function f is not continuous at $c = 0$.

32. The domain of the function f is the set $\{x|x \geq -4\}$, so f is defined at $c = 4$ with $f(4) = \sqrt{8} = 2\sqrt{2}$. Next,

$$\lim_{x \rightarrow 4^-} f(x) = \lim_{x \rightarrow 4^-} \sqrt{4 + x} = 2\sqrt{2}$$

and

$$\lim_{x \rightarrow 4^+} f(x) = \lim_{x \rightarrow 4^+} \sqrt{\frac{x^2 - 3x - 4}{x - 4}} = \lim_{x \rightarrow 4^+} \sqrt{\frac{(x - 4)(x + 1)}{x - 4}} = \lim_{x \rightarrow 4^+} \sqrt{x + 1} = \sqrt{5},$$

so that $\lim_{x \rightarrow 4} f(x)$ does not exist. Therefore, the function f is not continuous at $c = 4$.

33. Because

$$\lim_{x \rightarrow 2} f(x) = \lim_{x \rightarrow 2} \frac{x^2 - 4}{x - 2} = \lim_{x \rightarrow 2} \frac{(x - 2)(x + 2)}{x - 2} = \lim_{x \rightarrow 2} (x + 2) = 4,$$

$f(2)$ should be assigned the value 4. Then $\lim_{x \rightarrow 2} f(x) = f(2)$, and the resulting function will be continuous at $c = 2$.

34. Because

$$\lim_{x \rightarrow 3} f(x) = \lim_{x \rightarrow 3} \frac{x^2 + x - 12}{x - 3} = \lim_{x \rightarrow 3} \frac{(x - 3)(x + 4)}{x - 3} = \lim_{x \rightarrow 3} (x + 4) = 7,$$

$f(3)$ should be assigned the value 7. Then $\lim_{x \rightarrow 3} f(x) = f(3)$, and the resulting function will be continuous at $c = 3$.

35. Because

$$\lim_{x \rightarrow 1^-} f(x) = \lim_{x \rightarrow 1^-} (1 + x) = 2 \quad \text{and} \quad \lim_{x \rightarrow 1^+} f(x) = \lim_{x \rightarrow 1^+} 2x = 2,$$

it follows that $\lim_{x \rightarrow 1} f(x) = 2$, so $f(1)$ should be assigned the value 2. Then $\lim_{x \rightarrow 1} f(x) = f(1)$, and the resulting function will be continuous at $c = 1$.

36. Because

$$\lim_{x \rightarrow -1^-} f(x) = \lim_{x \rightarrow -1^-} (x^2 + 5x) = -4 \quad \text{and} \quad \lim_{x \rightarrow -1^+} f(x) = \lim_{x \rightarrow -1^+} (x - 3) = -4,$$

it follows that $\lim_{x \rightarrow -1} f(x) = -4$, so $f(-1)$ should be assigned the value -4. Then $\lim_{x \rightarrow -1} f(x) = f(-1)$, and the resulting function will be continuous at $c = -1$.

37. The domain of the function $f(x) = \frac{x^2 - 9}{x - 3}$ is the set $\{x|x \neq 3\}$, so that f is defined on the interval $[-3, 3)$. Let c be any number in the open interval $(-3, 3)$. Then

$$\lim_{x \rightarrow c} f(x) = \lim_{x \rightarrow c} \frac{x^2 - 9}{x - 3} = \frac{c^2 - 9}{c - 3} = f(c),$$

so f is continuous on the open interval $(-3, 3)$. Finally,

$$\lim_{x \rightarrow -3^+} f(x) = \lim_{x \rightarrow -3^+} \frac{x^2 - 9}{x - 3} = 0 = f(-3),$$

so f is also continuous from the right at $c = -3$. Therefore, the function f is continuous on the interval $[-3, 3)$.

38. The domain of the function $f(x) = 1 + \frac{1}{x}$ is the set $\{x|x \neq 0\}$, so that f is defined on the interval $[-1, 0)$. Let c be any number in the open interval $(-1, 0)$. Then

$$\lim_{x \rightarrow c} f(x) = \lim_{x \rightarrow c} \left(1 + \frac{1}{x}\right) = 1 + \frac{1}{c} = f(c),$$

so f is continuous on the open interval $(-1, 0)$. Finally,

$$\lim_{x \rightarrow -1^+} f(x) = \lim_{x \rightarrow -1^+} \left(1 + \frac{1}{x}\right) = 0 = f(-1),$$

so f is also continuous from the right at $c = -1$. Therefore, the function f is continuous on the interval $[-1, 0)$.

39. The domain of $f(x) = \frac{1}{\sqrt{x^2 - 9}}$ is the set $\{x| |x| > 3\}$, so that f is not defined anywhere on the closed interval $[-3, 3]$. Therefore, the function f is not continuous anywhere on the closed interval $[-3, 3]$. However, let c be any number in the domain of f . Then

$$\lim_{x \rightarrow c} f(x) = \lim_{x \rightarrow c} \frac{1}{\sqrt{x^2 - 9}} = \frac{1}{\sqrt{c^2 - 9}} = f(c),$$

so that the function f is continuous on its domain, the set $\{x|x < -3\} \cup \{x|x > 3\}$.

40. The domain of the function $f(x) = \sqrt{9 - x^2}$ is the set $\{x| -3 \leq x \leq 3\}$, so that f is defined on the closed interval $[-3, 3]$. Let c be any number in the open interval $(-3, 3)$. Then

$$\lim_{x \rightarrow c} f(x) = \lim_{x \rightarrow c} \sqrt{9 - x^2} = \sqrt{9 - c^2} = f(c),$$

so f is continuous on the open interval $(-3, 3)$. At $c = -3$,

$$\lim_{x \rightarrow -3^+} f(x) = \lim_{x \rightarrow -3^+} \sqrt{9 - x^2} = 0 = f(-3),$$

so f is also continuous from the right at $c = -3$. Finally, at $c = 3$,

$$\lim_{x \rightarrow 3^-} f(x) = \lim_{x \rightarrow 3^-} \sqrt{9 - x^2} = 0 = f(3),$$

and f is continuous from the left at $c = 3$. Therefore, the function f is continuous on the closed interval $[-3, 3]$.

41. Let $g(x) = 2x^2 + 5x$ and $h(x) = \frac{1}{x}$. The domain of the polynomial function g is the set of all real numbers, and the domain of the rational function h is the set $\{x|x \neq 0\}$. Each function is continuous on its domain. Because the function f is the difference of the functions g and h , the domain of f is the intersection of the domains of g and h ; that is, the domain of f is the set $\{x|x \neq 0\}$. The function f is continuous for all values x at which both g and h are continuous, so that f is continuous on the set $\{x|x \neq 0\}$.
42. Let $g(x) = x + 1$ and $h(x) = \frac{2x}{x^2 + 5}$. The domain of the polynomial function g is the set of all real numbers, and the domain of the rational function h is also the set of all real numbers (because $x^2 + 5$ is never equal to zero for any real number x). Each function is continuous on its domain. Because the function f is the sum of the functions g and h , the domain of f is the intersection of the domains of g and h ; that is, the domain of f is the set of all real numbers. The function f is continuous for all values x at which both g and h are continuous, so that f is continuous for all real numbers.

43. Let $g(x) = x - 1$ and $h(x) = x^2 + x + 1$. The domain of the polynomial function g is the set of all real numbers, and the domain of the polynomial function h is also the set of all real numbers. Each function is continuous on its domain. Because the function f is the product of the functions g and h , the domain of f is the intersection of the domains of g and h ; that is, the domain of f is the set of all real numbers. The function f is continuous for all values x at which both g and h are continuous, so that f is continuous for all real numbers.
44. Let $g(x) = \sqrt{x}$ and $h(x) = x^3 - 5$. The domain of the function g is the set $\{x|x \geq 0\}$, and the domain of the polynomial function h is the set of all real numbers. Each function is continuous on its domain. Because the function f is the product of the functions g and h , the domain of f is the intersection of the domains of g and h ; that is, the domain of f is the set $\{x|x \geq 0\}$. The function f is continuous at all values x at which both g and h are continuous, so that f is continuous on the set $\{x|x \geq 0\}$.
45. Let $g(x) = x - 9$ and $h(x) = \sqrt{x} - 3$. The domain of the polynomial function g is the set of all real numbers, and the domain of the function h is the set $\{x|x \geq 0\}$. Each function is continuous on its domain. Because the function f is the quotient of the functions g and h , the domain of f is the intersection of the domains of g and h excluding any x for which $h(x) = 0$; that is, the domain of f is the set $\{x|x \geq 0, x \neq 9\}$. The function f is continuous for all values x at which both g and h are continuous, excluding any x for which $h(x) = 0$, so that f is continuous on the set $\{x|x \geq 0, x \neq 9\}$.
46. Let $g(x) = x - 4$ and $h(x) = \sqrt{x} - 2$. The domain of the polynomial function g is the set of all real numbers, and the domain of the function h is the set $\{x|x \geq 0\}$. Each function is continuous on its domain. Because the function f is the quotient of the functions g and h , the domain of f is the intersection of the domains of g and h excluding any x for which $h(x) = 0$; that is, the domain of f is the set $\{x|x \geq 0, x \neq 4\}$. The function f is continuous for all values x at which both g and h are continuous, excluding any x for which $h(x) = 0$, so that f is continuous on the set $\{x|x \geq 0, x \neq 4\}$.
47. Let $g(x) = \sqrt{x}$ and $h(x) = \frac{x^2 + 1}{2 - x}$. The domain of the function g is the set $\{x|x \geq 0\}$, and the domain of the rational function h is the set $\{x|x \neq 2\}$. Each function is continuous on its domain. Moreover, the solution of the inequality $h(x) \geq 0$ is the set $\{x|x < 2\}$. Because f is the composition $g(h(x))$ and $h(x)$ is in the domain of g for $x < 2$, it follows that the domain of f is the set $\{x|x < 2\}$. Finally, the function f is continuous at c provided h is continuous at c and g is continuous at $h(c)$; thus, f is continuous on the set $\{x|x < 2\}$.
48. Let $g(x) = \sqrt{x}$ and $h(x) = \frac{4}{x^2 - 1}$. The domain of the function g is the set $\{x|x \geq 0\}$, and the domain of the rational function h is the set $\{x|x \neq \pm 1\}$. Each function is continuous on its domain. Moreover, the solution of the inequality $h(x) \geq 0$ is the set $\{x| |x| > 1\}$. Because f is the composition $g(h(x))$ and $h(x)$ is in the domain of g for $|x| > 1$, it follows that the domain of f is the set $\{x| |x| > 1\}$. Finally, the function f is continuous at c provided h is continuous at c and g is continuous at $h(c)$; thus, f is continuous on the set $\{x| |x| > 1\}$.
49. Let $g(x) = x^{2/3}$ and $h(x) = 2x^2 + 5x - 3$. The domain of the function g is the set of all real numbers, and the domain of the polynomial function h is also the set of all real numbers. Each function is continuous on its domain. Because f is the composition $g(h(x))$ and $h(x)$ is always in the domain of g , it follows that the domain of f is the set of all real numbers. Finally, the function f is continuous at c provided h is continuous at c and g is continuous at $h(c)$; thus, f is continuous on the set of all real numbers.

50. Let $g(x) = x^{1/2}$ and $h(x) = x + 2$. The domain of the function g is the set $\{x|x \geq 0\}$, and the domain of the polynomial function h is the set of all real numbers. Each function is continuous on its domain. Moreover, the solution of the inequality $h(x) \geq 0$ is the set $\{x|x \geq -2\}$. Because f is the composition $g(h(x))$ and $h(x)$ is in the domain of g for $x \geq -2$, it follows that the domain of f is the set $\{x|x \geq -2\}$. Finally, the function f is continuous at c provided h is continuous at c and g is continuous at $h(c)$; thus, f is continuous on the set $\{x|x \geq -2\}$.

51. Because f is defined at $c = 0$ with $f(0) = \sqrt{15}$ and

$$\lim_{x \rightarrow 0} f(x) = \lim_{x \rightarrow 0} \sqrt{15 - 3x} = \sqrt{15} = f(0),$$

the function f is continuous at $c = 0$.

52. Because

$$\lim_{x \rightarrow 4^-} f(x) = \lim_{x \rightarrow 4^-} \lfloor x - 2 \rfloor = 1 \quad \text{but} \quad \lim_{x \rightarrow 4^+} f(x) = \lim_{x \rightarrow 4^+} \lfloor x - 2 \rfloor = 2,$$

it follows that $\lim_{x \rightarrow 4} f(x)$ does not exist and f is not continuous at $c = 4$.

53. Because

$$\lim_{x \rightarrow 3^-} f(x) = \lim_{x \rightarrow 3^-} (9 - x^2) = 0 \quad \text{but} \quad \lim_{x \rightarrow 3^+} f(x) = \lim_{x \rightarrow 3^+} \lfloor x - 2 \rfloor = 1,$$

it follows that $\lim_{x \rightarrow 3} f(x)$ does not exist and f is not continuous at $c = 3$.

54. Because

$$\lim_{x \rightarrow 2^-} f(x) = \lim_{x \rightarrow 2^-} \sqrt{15 - 3x} = 3 \quad \text{but} \quad \lim_{x \rightarrow 2^+} f(x) = \lim_{x \rightarrow 2^+} (9 - x^2) = 5,$$

it follows that $\lim_{x \rightarrow 2} f(x)$ does not exist and f is not continuous at $c = 2$.

55. Because f is defined at $c = 1$ with $f(1) = \sqrt{12} = 2\sqrt{3}$ and

$$\lim_{x \rightarrow 1} f(x) = \lim_{x \rightarrow 1} \sqrt{15 - 3x} = \sqrt{12} = 2\sqrt{3} = f(1),$$

the function f is continuous at $c = 1$.

56. Because f is defined at $c = 2.5$ with $f(2.5) = 2.75$ and

$$\lim_{x \rightarrow 2.5} f(x) = \lim_{x \rightarrow 2.5} (9 - x^2) = 9 - 2.5^2 = 2.75 = f(2.5),$$

the function f is continuous at $c = 2.5$.

57. (a) A graph of the function f is shown below

- (b) Based on the graph from part (a), the function f appears to be continuous on the set of all real numbers.
- (c) The polynomial functions $x^3 - 8$ and $x - 2$ are continuous on the set of all real numbers. Because the function f is the quotient of these two polynomials, f is continuous on the set of all real numbers excluding any values for x at which $x - 2 = 0$. Thus, f is continuous on the set $\{x | x \neq 2\}$.
- (d) Answers will vary. One possible response is that graphing technology can be a useful tool to suggest where a function is continuous, but “conclusions” drawn from graphing technology should always be confirmed using some basic analysis.
58. (a) A graph of the function f is shown below

- (b) Based on the graph from part (a), the function f appears to be continuous on the set of all real numbers.
- (c) The polynomial functions $x^2 - 3x + 2$ and $3x - 6$ are continuous on the set of all real numbers. Because the function f is the quotient of these two polynomials, f is continuous on the set of all real numbers excluding any values for x at which $3x - 6 = 0$. Thus, f is continuous on the set $\{x | x \neq 2\}$.
- (d) Answers will vary. One possible response is that graphing technology can be a useful tool to suggest where a function is continuous, but “conclusions” drawn from graphing technology should always be confirmed using some basic analysis.
59. The polynomial function $f(x) = x^3 - 3x$ is continuous for all real numbers, so it is continuous on the closed interval $[-2, 2]$. Because $f(-2) = (-2)^3 - 3(-2) = -2 < 0$ and $f(2) = 2^3 - 3(2) = 2 > 0$, the Intermediate Value Theorem guarantees that f must have a zero on the interval $(-2, 2)$.
60. The polynomial function $f(x) = x^4 - 1$ is continuous for all real numbers, so it is continuous on the closed interval $[-2, 2]$. Because $f(-2) = (-2)^4 - 1 = 15 > 0$ and $f(2) = 2^4 - 1 = 15 > 0$, the Intermediate Value Theorem gives no information about the presence of a zero of f on the interval $(-2, 2)$.
61. The domain of the function $f(x) = \frac{x}{(x+1)^2} - 1$ is the set $\{x | x \neq -1\}$. Because f is the difference of a rational function and a polynomial function, it is continuous on its domain. It follows that f is continuous on the closed interval $[10, 20]$. Now,
- $$f(10) = \frac{10}{11^2} - 1 = -\frac{111}{121} < 0 \quad \text{and} \quad f(20) = \frac{20}{21^2} - 1 = -\frac{421}{441} < 0,$$
- so the Intermediate Value Theorem gives no information about the presence of a zero of f on the interval $(10, 20)$.

62. The polynomial function $f(x) = x^3 - 2x^2 - x + 2$ is continuous for all real numbers, so it is continuous on the closed interval $[3, 4]$. Because $f(3) = 3^3 - 2(3)^2 - 3 + 2 = 8 > 0$ and $f(4) = 4^3 - 2(4)^2 - 4 + 2 = 30 > 0$, the Intermediate Value Theorem gives no information about the presence of a zero of f on the interval $(3, 4)$.
63. The domain of the function $f(x) = \frac{x^3 - 1}{x - 1}$ is the set $\{x | x \neq 1\}$. Because the closed interval $[0, 2]$ contains $x = 1$, f is not continuous on this interval, so the Intermediate Value Theorem does not apply. Therefore, the Intermediate Value Theorem gives no information about the presence of a zero of f on the interval $(0, 2)$.
64. The domain of the function $f(x) = \frac{x^2 + 3x + 2}{x^2 - 1}$ is the set $\{x | x \neq \pm 1\}$. Because the closed interval $[-3, 0]$ contains $x = -1$, f is not continuous on this interval, so the Intermediate Value Theorem does not apply. Therefore, the Intermediate Value Theorem gives no information about the presence of a zero of f on the interval $(-3, 0)$.
65. The polynomial function $f(x) = x^3 + 3x - 5$ is continuous for all real numbers, so it is continuous on the closed interval $[1, 2]$. Because $f(1) = 1^3 + 3(1) - 5 = -1 < 0$ and $f(2) = 2^3 + 3(2) - 5 = 9 > 0$, the Intermediate Value Theorem guarantees that f must have a zero on the interval $(1, 2)$. To approximate this zero, subdivide the interval $[1, 2]$ into 10 subintervals, each of length 0.1, and evaluate f at each endpoint. The results are shown in the first two columns of the table below. Because $f(1.1) = -0.369 < 0$ and $f(1.2) = 0.328 > 0$, the Intermediate Value Theorem guarantees the zero lies in the interval $(1.1, 1.2)$. Repeating the process by subdividing the interval $[1.1, 1.2]$ into 10 subintervals of length 0.01 yields the results in the middle two columns of the table, where the function values have been rounded to five decimal places for display purposes. The zero has now been bracketed in the interval $(1.15, 1.16)$. Repeating the subdivision process once more, the results in the last two columns of the table are produced, again with the function values rounded to five decimal places. Examining the function values in the last column, it follows that the zero of the function f is $[1.154]$, correct to three decimal places.

[1, 2]		[1.1, 1.2]		[1.15, 1.16]	
x	$f(x)$	x	$f(x)$	x	$f(x)$
1.0	-1.000	1.10	-0.36900	1.150	-0.02913

66. The polynomial function $f(x) = x^3 - 4x + 2$ is continuous for all real numbers, so it is continuous on the closed interval $[1, 2]$. Because $f(1) = 1^3 - 4(1) + 2 = -1 < 0$ and $f(2) = 2^3 - 4(2) + 2 = 2 > 0$, the Intermediate Value Theorem guarantees that f must have a zero on the interval $(1, 2)$. To approximate this zero, subdivide the interval $[1, 2]$ into 10 subintervals, each of length 0.1, and evaluate f at each endpoint. The results are shown in the first two columns of the table below. Because $f(1.6) = -0.304 < 0$ and $f(1.7) = 0.113 > 0$, the Intermediate Value Theorem guarantees the zero lies in the interval $(1.6, 1.7)$. Repeating the process by subdividing the interval $[1.6, 1.7]$ into 10 subintervals of length 0.01 yields the results in the middle two columns of the table, where the function values have been rounded to five decimal places for display purposes. The zero has now been bracketed in the interval $(1.67, 1.68)$. Repeating the subdivision process once more,

the results in the last two columns of the table are produced, again with the function values rounded to five decimal places. Examining the function values in the last column, it follows that the zero of the function f is $\boxed{1.675}$, correct to three decimal places.

67. The polynomial function $f(x) = 2x^3 + 3x^2 + 4x - 1$ is continuous for all real numbers, so it is continuous on the closed interval $[0, 1]$. Because $f(0) = -1 < 0$ and $f(1) = 2 + 3 + 4 - 1 = 8 > 0$, the Intermediate Value Theorem guarantees that f must have a zero on the interval $(0, 1)$. To approximate this zero, subdivide the interval $[0, 1]$ into 10 subintervals, each of length 0.1, and evaluate f at each endpoint. The results are shown in the first two columns of the table below. Because $f(0.2) = -0.064 < 0$ and $f(0.3) = 0.524 > 0$, the Intermediate Value Theorem guarantees the zero lies in the interval $(0.2, 0.3)$. Repeating the process by subdividing the interval $[0.2, 0.3]$ into 10 subintervals of length 0.01 yields the results in the middle two columns of the table, where the function values have been rounded to five decimal places for display purposes. The zero has now been bracketed in the interval $(0.21, 0.22)$. Repeating the subdivision process once more, the results in the last two columns of the table are produced, again with the function values rounded to five decimal places. Examining the function values in the last column, it follows that the zero of the function f is $\boxed{0.211}$, correct to three decimal places.

68. The polynomial function $f(x) = x^3 - x^2 - 2x + 1$ is continuous for all real numbers, so it is continuous on the closed interval $[0, 1]$. Because $f(0) = 1 > 0$ and $f(1) = 1 - 1 - 2 + 1 = -1 < 0$, the Intermediate Value Theorem guarantees that f must have a zero on the interval $(0, 1)$. To approximate this zero, subdivide the interval $[0, 1]$ into 10 subintervals, each of length 0.1, and evaluate f at each endpoint. The results are shown in the first two columns of the table below. Because $f(0.4) = 0.104 > 0$ and $f(0.5) = -0.125 < 0$, the Intermediate Value Theorem guarantees the zero lies in the interval $(0.4, 0.5)$. Repeating the process by subdividing the interval $[0.4, 0.5]$ into 10 subintervals of length 0.01 yields the results in the middle two columns of the table, where the function values have been rounded to

five decimal places for display purposes. The zero has now been bracketed in the interval $(0.44, 0.45)$. Repeating the subdivision process once more, the results in the last two columns of the table are produced, again with the function values rounded to five decimal places. Examining the function values in the last column, it follows that the zero of the function f is $\boxed{0.445}$, correct to three decimal places.

$[0, 1]$		$[0.4, 0.5]$		$[0.44, 0.45]$	
x	$f(x)$	x	$f(x)$	x	$f(x)$
0.0	1.000	0.40	0.10400	0.440	0.01158
0.1	0.791	0.41	0.08082	0.441	0.00929

69. The polynomial function $f(x) = x^3 - 6x - 12$ is continuous for all real numbers, so it is continuous on the closed interval $[3, 4]$. Because $f(3) = 3^3 - 6(3) - 12 = -3 < 0$ and $f(4) = 4^3 - 6(4) - 12 = 28 > 0$, the Intermediate Value Theorem guarantees that f must have a zero on the interval $(3, 4)$. To approximate this zero, subdivide the interval $[3, 4]$ into 10 subintervals, each of length 0.1, and evaluate f at each endpoint. The results are shown in the first two columns of the table below. Because $f(3.1) = -0.809 < 0$ and $f(3.2) = 1.568 > 0$, the Intermediate Value Theorem guarantees the zero lies in the interval $(3.1, 3.2)$. Repeating the process by subdividing the interval $[3.1, 3.2]$ into 10 subintervals of length 0.01 yields the results in the middle two columns of the table, where the function values have been rounded to five decimal places for display purposes. The zero has now been bracketed in the interval $(3.13, 3.14)$. Repeating the subdivision process once more, the results in the last two columns of the table are produced, again with the function values rounded to five decimal places. Examining the function values in the last column, it follows that the zero of the function f is $\boxed{3.134}$, correct to three decimal places.

70. The polynomial function $f(x) = 3x^3 + 5x - 40$ is continuous for all real numbers, so it is continuous on the closed interval $[2, 3]$. Because $f(2) = 3(2)^3 + 5(2) - 40 = -6 < 0$ and $f(3) = 3(3)^3 + 5(3) - 40 = 56 > 0$, the Intermediate Value Theorem guarantees that f must have a zero on the interval $(2, 3)$. To approximate this zero, subdivide the interval $[2, 3]$ into 10 subintervals, each of length 0.1, and evaluate f at each endpoint. The results are shown in the first two columns of the table below. Because $f(2.1) = -1.717 < 0$ and $f(2.2) = 2.2944 > 0$, the Intermediate Value

Theorem guarantees the zero lies in the interval $(2.1, 2.2)$. Repeating the process by subdividing the interval $[2.1, 2.2]$ into 10 subintervals of length 0.01 yields the results in the middle two columns of the table, where the function values have been rounded to five decimal places for display purposes. The zero has now been bracketed in the interval $(2.13, 2.14)$. Repeating the subdivision process once more, the results in the last two columns of the table are produced, again with the function values rounded to five decimal places. Examining the function values in the last column, it follows that the zero of the function f is $\boxed{2.137}$, correct to three decimal places.

$[2, 3]$		$[2.1, 2.2]$		$[2.13, 2.14]$	
x	$f(x)$	x	$f(x)$	x	$f(x)$
2.0	-6.000	2.10	-1.71700	2.130	-0.35921
2.1	-1.717	2.11	-1.26281	2.131	-0.31336
2.2	2.944	2.12	-0.81562	2.132	-0.26747
2.3	8.001	2.13	-0.35921	2.133	-0.22154

71. The polynomial function $f(x) = x^4 - 2x^3 + 21x - 23$ is continuous for all real numbers, so it is continuous on the closed interval $[1, 2]$. Because $f(1) = 1 - 2 + 21 - 23 = -3 < 0$ and $f(2) = 2^4 - 2(2)^3 + 21(2) - 23 = 19 > 0$, the Intermediate Value Theorem guarantees that f must have a zero on the interval $(1, 2)$. To approximate this zero, subdivide the interval $[1, 2]$ into 10 subintervals, each of length 0.1, and evaluate f at each endpoint. The results are shown in the first two columns of the table below. Because $f(1.1) = -1.0979 < 0$ and $f(1.2) = 0.8176 > 0$, the Intermediate Value Theorem guarantees the zero lies in the interval $(1.1, 1.2)$. Repeating the process by subdividing the interval $[1.1, 1.2]$ into 10 subintervals of length 0.01 yields the results in the middle two columns of the table, where the function values have been rounded to five decimal places for display purposes. The zero has now been bracketed in the interval $(1.15, 1.16)$. Repeating the subdivision process once more, the results in the last two columns of the table are produced, again with the function values rounded to five decimal places. Examining the function values in the last column, it follows that the zero of the function f is $\boxed{1.157}$, correct to three decimal places.

$[1, 2]$		$[1.1, 1.2]$		$[1.15, 1.16]$	
x	$f(x)$	x	$f(x)$	x	$f(x)$
1.0	-3.0000	1.10	-1.09790	1.150	-0.14274
1.1	-1.0979	1.11	-0.90719	1.151	-0.12359
1.2	0.8176	1.12	-0.71634	1.152	-0.10444
1.3	2.7621	1.13	-0.52532	1.153	-0.08529
1.4	4.7536	1.14	-0.33413	1.154	-0.06613
1.5	6.8125	1.15	-0.14274	1.155	-0.04698
1.6	8.9616	1.16	0.04885	1.156	-0.02781
1.7	11.2261	1.17	0.24066	1.157	-0.00865
1.8	13.6336	1.18	0.43271	1.158	0.01051
1.9	16.2141	1.19	0.62502	1.159	0.02968
2.0	19.0000	1.20	0.81760	1.160	0.04885

72. The polynomial function $f(x) = x^4 - x^3 + x - 2$ is continuous for all real numbers, so it is continuous on the closed interval $[1, 2]$. Because $f(1) = 1 - 1 + 1 - 2 = -1 < 0$ and $f(2) = 2^4 - 2^3 + 2 - 2 = 8 > 0$, the Intermediate Value Theorem guarantees that f must have a zero on the interval $(1, 2)$. To approximate this zero, subdivide the interval $[1, 2]$ into 10 subintervals,

each of length 0.1, and evaluate f at each endpoint. The results are shown in the first two columns of the table below. Because $f(1.3) = -0.0409 < 0$ and $f(1.4) = 0.4976 > 0$, the Intermediate Value Theorem guarantees the zero lies in the interval $(1.3, 1.4)$. Repeating the process by subdividing the interval $[1.3, 1.4]$ into 10 subintervals of length 0.01 yields the results in the middle two columns of the table, where the function values have been rounded to five decimal places for display purposes. The zero has now been bracketed in the interval $(1.30, 1.31)$. Repeating the subdivision process once more, the results in the last two columns of the table are produced, again with the function values rounded to five decimal places. Examining the function values in the last column, it follows that the zero of the function f is $\boxed{1.308}$, correct to three decimal places.

[1, 2]		[1.3, 1.4]		[1.30, 1.31]	
x	$f(x)$	x	$f(x)$	x	$f(x)$
1.0	-1.0000	1.30	-0.04090	1.300	-0.04090
1.1	-0.7669	1.31	0.00691	1.301	-0.03618
1.2	-0.4544	1.32	0.05599	1.302	-0.03144
1.3	-0.0409	1.33	0.10637	1.303	-0.02669

73. (a) The polynomial function $x^2 + 4x$ is continuous on the set of all real numbers and is non-negative on the set $\{x|x \leq -4\} \cup \{x|x \geq 0\}$. The function $f(x) = \sqrt{x^2 + 4x} - 2$ is therefore continuous on the set $\{x|x \leq -4\} \cup \{x|x \geq 0\}$, which contains the closed interval $[0, 1]$. Because $f(0) = \sqrt{0} - 2 = -2 < 0$ and $f(1) = \sqrt{5} - 2 \approx 0.236 > 0$, the Intermediate Value Theorem guarantees that f must have a zero on the interval $(0, 1)$.
- (b) Using the `FindRoot` command in the computer algebra system *Mathematica* produces the zero $\boxed{x \approx 0.828}$, rounded to three decimal places.
74. (a) The polynomial function $f(x) = x^3 - x + 2$ is continuous for all real numbers, so it is continuous on the closed interval $[-2, 0]$. Because $f(-2) = (-2)^3 - (-2) + 2 = -4 < 0$ and $f(0) = 2 > 0$, the Intermediate Value Theorem guarantees that f must have a zero on the interval $(-2, 0)$.
- (b) Using the `FindRoot` command in the computer algebra system *Mathematica* produces the zero $\boxed{x \approx -1.521}$, rounded to three decimal places.

Applications and Extensions

75. The function $u_1(t)$ is defined at $c = 1$ with $u_1(1) = 1$. Next,

$$\lim_{t \rightarrow 1^-} u_1(t) = \lim_{t \rightarrow 1^-} 0 = 0 \quad \text{and} \quad \lim_{t \rightarrow 1^+} u_1(t) = \lim_{t \rightarrow 1^+} 1 = 1.$$

Because the two one-sided limits at t approaches 1 are not equal, $\lim_{t \rightarrow 1} u_1(t)$ does not exist. Therefore, the function $u_1(t)$ is not continuous at $c = 1$.

76. The function $u_3(t)$ is defined at $c = 3$ with $u_3(3) = 1$. Next,

$$\lim_{t \rightarrow 3^-} u_3(t) = \lim_{t \rightarrow 3^-} 0 = 0 \quad \text{and} \quad \lim_{t \rightarrow 3^+} u_3(t) = \lim_{t \rightarrow 3^+} 1 = 1.$$

Because the two one-sided limits at t approaches 3 are not equal, $\lim_{t \rightarrow 3} u_3(t)$ does not exist. Therefore, the function $u_3(t)$ is not continuous at $c = 3$.

77. The function f is continuous on the intervals $(-\infty, -1)$, $(-1, 1)$, and $(1, \infty)$ because the function is a polynomial on each of these intervals. At $x = -1$,

$$\lim_{x \rightarrow -1^-} f(x) = \lim_{x \rightarrow -1^-} (x^2 - 1) = 0 \quad \text{and} \quad \lim_{x \rightarrow -1^+} f(x) = \lim_{x \rightarrow -1^+} (1 - x^2) = 0,$$

so that $\lim_{x \rightarrow -1} f(x)$ exists and is equal to 0. As $f(-1) = 0$, it follows that f is continuous at $x = -1$. Similarly, at $x = 1$,

$$\lim_{x \rightarrow 1^-} f(x) = \lim_{x \rightarrow 1^-} (1 - x^2) = 0 \quad \text{and} \quad \lim_{x \rightarrow 1^+} f(x) = \lim_{x \rightarrow 1^+} (x^2 - 1) = 0,$$

so that $\lim_{x \rightarrow 1} f(x)$ exists and is equal to 0. As $f(1) = 0$, it follows that f is continuous at $x = 1$. Hence, f is continuous on the set of all real numbers. A graph of f is shown below.

78. The function f is continuous on the intervals $(-\infty, -2)$, $(-2, 2)$, and $(2, \infty)$ because the component functions are continuous on each of these intervals. At $x = -2$,

$$\lim_{x \rightarrow -2^-} f(x) = \lim_{x \rightarrow -2^-} (|x| - 2) = 0 \quad \text{and} \quad \lim_{x \rightarrow -2^+} f(x) = \lim_{x \rightarrow -2^+} \sqrt{4 - x^2} = 0,$$

so that $\lim_{x \rightarrow -2} f(x)$ exists and is equal to 0. As $f(-2) = 0$, it follows that f is continuous at $x = -2$. Similarly, at $x = 2$,

$$\lim_{x \rightarrow 2^-} f(x) = \lim_{x \rightarrow 2^-} \sqrt{4 - x^2} = 0 \quad \text{and} \quad \lim_{x \rightarrow 2^+} f(x) = \lim_{x \rightarrow 2^+} (|x| - 2) = 0,$$

so that $\lim_{x \rightarrow 2} f(x)$ exists and is equal to 0. As $f(2) = 0$, it follows that f is continuous at $x = 2$. Hence, f is continuous on the set of all real numbers. A graph of f is shown below.

79. (a) Because the Postal Service rounds the weight of the letter up to next whole number of ounces, the first-class postage charged is

$$C(w) = \begin{cases} 0.46, & \text{if } 0 < w \leq 1 \\ 0.66, & \text{if } 1 < w \leq 2 \\ 0.86, & \text{if } 2 < w \leq 3 \\ 1.06, & \text{if } 3 < w \leq 3.5. \end{cases}$$

where postage is measured in dollars and weight is measured in ounces. This can be written compactly in terms of the ceiling function as

$$C(w) = 0.46 + 0.20[w - 1].$$

- (b) The domain of C is the set $\{w | 0 < w \leq 3.5\}$.
- (c) The function C is continuous on the intervals $(0, 1)$, $(1, 2)$, $(2, 3)$, and $(3, 3.5)$ because the function is a constant (polynomial) on each of these intervals. At $w = 1$,

$$\lim_{w \rightarrow 1^-} C(w) = \lim_{w \rightarrow 1^-} 0.46 = 0.46 \quad \text{and} \quad \lim_{w \rightarrow 1^+} = \lim_{w \rightarrow 1^+} 0.66 = 0.66,$$

so that $\lim_{w \rightarrow 1} C(w)$ does not exist. Similarly, at $w = 2$ and $w = 3$,

$$\lim_{w \rightarrow 2^-} C(w) = \lim_{w \rightarrow 2^-} 0.66 = 0.66 \quad \text{and} \quad \lim_{w \rightarrow 2^+} = \lim_{w \rightarrow 2^+} 0.86 = 0.86,$$

and

$$\lim_{w \rightarrow 3^-} C(w) = \lim_{w \rightarrow 3^-} 0.86 = 0.86 \quad \text{and} \quad \lim_{w \rightarrow 3^+} = \lim_{w \rightarrow 3^+} 1.06 = 1.06,$$

respectively, so that $\lim_{w \rightarrow 2} C(w)$ does not exist and $\lim_{w \rightarrow 3} C(w)$ does not exist. Therefore, C is not continuous at $w = 1$, $w = 2$, or $w = 3$. However,

$$\lim_{w \rightarrow 1^-} C(w) = 0.46 = C(1), \quad \lim_{w \rightarrow 2^-} C(w) = 0.66 = C(2), \quad \text{and} \quad \lim_{w \rightarrow 3^-} C(w) = 0.86 = C(3),$$

so C is continuous from the left at $w = 1$, $w = 2$, and $w = 3$. Additionally,

$$\lim_{w \rightarrow 3.5^-} C(w) = \lim_{w \rightarrow 3.5^-} 1.06 = 1.06 = C(3.5),$$

so C is continuous from the left at $w = 3.5$. Thus, C is continuous on the intervals $(0, 1]$, $(1, 2]$, $(2, 3]$, and $(3, 3.5]$.

- (d) At each number where C is not continuous ($w = 1$, $w = 2$, and $w = 3$), the two one-sided limits exist but are not equal, so each discontinuity is a **jump discontinuity**.
- (e) Answers will vary. One possible response is that because any fraction of an ounce results in a charge for a full ounce, it is in the consumer's best interest to have letters weigh as close as possible to a whole number of ounces, without going over.
80. (a) Because the Postal Service rounds the weight of the letter up to next whole number of ounces, the first-class postage charged is

$$C(w) = 0.92 + 0.20[w - 1],$$

for $0 < w \leq 13$, where postage is measured in dollars and weight is measured in ounces.

- (b) The domain of C is the set $\{w | 0 < w \leq 13\}$.

- (c) Let c be any whole number between 1 and 12, inclusive. Then C is continuous on the interval $(c-1, c)$, because the function is a constant (polynomial) on this interval. The function C is continuous on the interval $(12, 13)$ for the same reason. Now, at $w = c$,

$$\lim_{w \rightarrow c^-} C(w) = \lim_{w \rightarrow c^-} (0.92 + 0.20\lceil w - 1 \rceil) = 0.92 + 0.20(c-1)$$

and

$$\lim_{w \rightarrow c^+} C(w) = \lim_{w \rightarrow c^+} (0.92 + 0.20\lceil w - 1 \rceil) = 0.92 + 0.20c,$$

so that $\lim_{w \rightarrow c} C(w)$ does not exist and C is not continuous at $w = c$. However

$$\lim_{w \rightarrow c^-} C(w) = 0.92 + 0.20(c-1) = C(c),$$

so C is continuous from the left at $w = c$. Additionally,

$$\begin{aligned} \lim_{w \rightarrow 13^-} C(w) &= \lim_{w \rightarrow 13^-} (0.92 + 0.20\lceil w - 1 \rceil) = 0.92 + 0.20(12) \\ &= 3.32 = C(13), \end{aligned}$$

so C is continuous from the left at $w = 13$. Finally, C is continuous on the intervals

$(0, 1],$	$(1, 2],$	$(2, 3],$	$(3, 4],$	$(4, 5],$	$(5, 6],$	$(6, 7],$
$(7, 8],$	$(8, 9],$	$(9, 10],$	$(10, 11],$	$(11, 12],$	$(12, 13].$	

- (d) At each number where C is not continuous, the two one-sided limits exist but are not equal, so each discontinuity is a jump discontinuity.
- (e) Answers will vary. One possible response is that because any fraction of an ounce results in a charge for a full ounce, it is in the consumer's best interest to have retail flats weigh as close as possible to a whole number of ounces, without going over.
81. (a) Let x denote the monthly usage of natural gas, measured in therms, and let $C(x)$ denote the monthly cost. If $x \leq 50$, the cost consists of the monthly customer charge of \$22.13, the distribution charge of \$0.25963 per therm, and the gas charge of \$0.3631 per therm. Thus,

$$C(x) = 22.13 + 0.25963x + 0.3631x = 22.13 + 0.62273x.$$

On the other hand, if $x > 50$, the cost consists of the monthly customer charge of \$22.13, a charge of \$12.98 for the first 50 therms, the distribution charge of \$0.11806 for each therm over 50, and the gas charge of \$0.3631 per therm. Thus,

$$C(x) = 22.13 + 12.98 + 0.11806(x - 50) + 0.3631x = 29.207 + 0.48116x.$$

Bringing these two pieces together, the complete cost function is

$C(x) = \begin{cases} 22.13 + 0.62273x, & \text{if } 0 \leq x \leq 50 \\ 29.207 + 0.48116x, & \text{if } x > 50. \end{cases}$

- (b) The domain of C is the set $\{x | x \geq 0\}$.
- (c) The function C is continuous on the intervals $(0, 50)$ and $(50, \infty)$ because it is a polynomial on each of these intervals. At $x = 50$,

$$\lim_{x \rightarrow 50^-} C(x) = \lim_{x \rightarrow 50^-} (22.13 + 0.62273x) = \$53.27$$

and

$$\lim_{x \rightarrow 50^+} C(x) = \lim_{x \rightarrow 50^+} (29.207 + 0.48116x) = \$53.27,$$

so that $\lim_{x \rightarrow 50} C(x)$ exists and is equal to $C(50) = \$53.27$. Therefore, C is continuous at $x = 50$. Because

$$\lim_{x \rightarrow 0^+} C(x) = \lim_{x \rightarrow 0^+} (22.13 + 0.62273x) = 22.13 = C(0),$$

C is continuous from the right at $x = 0$. Therefore, C is continuous on the interval $[0, \infty)$.

- (d) The function C is continuous on its domain.
- (e) Answers will vary. One possible response is that from a purely mathematical standpoint, the two one-sided limits as x approaches 50 are not equal; however, from a practical cost standpoint, the two one-sided limits correspond to the same cost (\$53.27). Thus, from a practical standpoint, the cost function is continuous at $x = 50$.
82. (a) Using the rate schedule provided,

$$C(x) = \begin{cases} 9.00, & \text{if } 0 \leq x \leq 10 \\ 9.00 + 0.95(x - 10), & \text{if } 10 < x \leq 30 \\ 28.00 + 1.65(x - 30), & \text{if } 30 < x \leq 100 \\ 143.50 + 2.20(x - 100), & \text{if } x > 100. \end{cases}$$

- (b) The domain of C is the set $\{x | x \geq 0\}$.
- (c) The function C is continuous on the intervals $(0, 10)$, $(10, 30)$, $(30, 100)$, and $(100, \infty)$, because it is a polynomial on each of these intervals. At $x = 10$,

$$\lim_{x \rightarrow 10^-} C(x) = \lim_{x \rightarrow 10^-} 9.00 = 9.00$$

and

$$\lim_{x \rightarrow 10^+} C(x) = \lim_{x \rightarrow 10^+} [9.00 + 0.95(x - 10)] = 9.00 + 0.95(10 - 10) = 9.00,$$

so that $\lim_{x \rightarrow 10} C(x)$ exists and is equal to 9.00. As $C(10) = 9.00$, it follows that C is continuous at $x = 10$. Similarly,

$$\lim_{x \rightarrow 30^-} C(x) = \lim_{x \rightarrow 30^-} [9.00 + 0.95(x - 10)] = 9.00 + 0.95(30 - 10) = 28.00$$

and

$$\lim_{x \rightarrow 30^+} C(x) = \lim_{x \rightarrow 30^+} [28.00 + 1.65(x - 30)] = 28.00 + 1.65(30 - 30) = 28.00,$$

so that $\lim_{x \rightarrow 30} C(x) = 28.00 = C(30)$ and C is continuous at $x = 30$. At $w = 100$,

$$\lim_{x \rightarrow 100^-} C(x) = \lim_{x \rightarrow 100^-} [28.00 + 1.65(x - 30)] = 28.00 + 1.65(100 - 30) = 143.50$$

and

$$\lim_{x \rightarrow 100^+} C(x) = \lim_{x \rightarrow 100^+} [143.50 + 2.20(x - 100)] = 143.50 + 2.20(100 - 100) = 143.50,$$

so that $\lim_{x \rightarrow 100} C(x)$ exists and is equal to $143.50 = C(100)$. Thus, C is continuous at $x = 100$. Finally,

$$\lim_{x \rightarrow 0^+} C(x) = \lim_{x \rightarrow 0^+} 9.00 = 9.00 = C(0),$$

so C is continuous from the right at $x = 0$. Thus, C is continuous on $[0, \infty)$.

- (d) The function C is continuous on its domain.

- (e) Answers will vary. One possible response is that there is no “penalty” to the consumer who goes just a little over 10,000 or 30,000 or 100,000 gallons rather than trying to keep consumption at or a little below these amounts.

83. (a) Because

$$\lim_{r \rightarrow R^-} g(r) = \lim_{r \rightarrow R^-} \frac{Gm}{R^3} r = \frac{Gm}{R^2}$$

and

$$\lim_{r \rightarrow R^+} g(r) = \lim_{r \rightarrow R^+} \frac{Gm}{r^2} = \frac{Gm}{R^2}$$

are equal, $\boxed{g(R) \text{ must equal } \frac{Gm}{R^2}}$ in order for the gravitational field of Europa to be continuous at its surface.

- (b) With $G = 6.67 \times 10^{-11} \text{ m}^3 \text{ kg}^{-1} \text{ s}^{-2}$, $m = 4.8 \times 10^{22} \text{ kg}$ and $R = 1.569 \times 10^6 \text{ m}$,

$$g(R) = \frac{6.67 \times 10^{-11} \text{ m}^3 \text{ kg}^{-1} \text{ s}^{-2} \cdot 4.8 \times 10^{22} \text{ kg}}{(1.569 \times 10^6 \text{ m})^2} \approx \boxed{1.3 \text{ m/s}^2}.$$

- (c) Europa’s gravity is $\boxed{\text{less than}}$ that on Earth.

84. The function f is continuous on the intervals $(-\infty, 0)$, $(0, 1)$, and $(1, \infty)$, because it is a polynomial on each of these intervals. At $x = 0$,

$$\lim_{x \rightarrow 0^-} f(x) = \lim_{x \rightarrow 0^-} (x - 1)^2 = 1$$

and

$$\lim_{x \rightarrow 0^+} f(x) = \lim_{x \rightarrow 0^+} (A - x)^2 = A^2 = f(0).$$

For f to be continuous at $x = 0$, the constant A must satisfy $A^2 = 1$, or $A = \pm 1$. At $x = 1$,

$$\lim_{x \rightarrow 1^-} f(x) = \lim_{x \rightarrow 1^-} (A - x)^2 = (A - 1)^2$$

and

$$\lim_{x \rightarrow 1^+} f(x) = \lim_{x \rightarrow 1^+} (x + B) = 1 + B = f(1).$$

For f to be continuous at $x = 1$, the constant B must satisfy $1 + B = (A - 1)^2$, or $B = A^2 - 2A$. There are therefore two sets of values for A and B for which the function f is continuous for all x : $\boxed{\{A = 1, B = -1\} \text{ and } \{A = -1, B = 3\}}$. The figure below left displays the graph with $A = 1$ and $B = -1$; the figure below right displays the graph with $A = -1$ and $B = 3$.

85. The function f is continuous on the intervals $(-\infty, 4)$, $(4, 9)$, and $(9, \infty)$, because it is a polynomial on each of these intervals. At $x = 4$,

$$\lim_{x \rightarrow 4^-} f(x) = \lim_{x \rightarrow 4^-} (x + A) = 4 + A$$

and

$$\lim_{x \rightarrow 4^+} f(x) = \lim_{x \rightarrow 4^+} (x - 1)^2 = 9 = f(4).$$

For f to be continuous at $x = 4$, the constant A must satisfy $4 + A = 9$, or $A = 5$. At $x = 9$,

$$\lim_{x \rightarrow 9^-} f(x) = \lim_{x \rightarrow 9^-} (x - 1)^2 = 64 = f(9)$$

and

$$\lim_{x \rightarrow 9^+} f(x) = \lim_{x \rightarrow 9^+} (Bx + 1) = 9B + 1.$$

For f to be continuous at $x = 9$, the constant B must satisfy $9B + 1 = 64$, or $B = 7$. Therefore, the function f will be continuous for all x provided $A = 5$ and $B = 7$. The graph of the resulting function is shown below

86. In order to make f continuous at $x = 2$, k should be set equal to

$$\begin{aligned} \lim_{x \rightarrow 2} f(x) &= \lim_{x \rightarrow 2} \frac{\sqrt{2x+5} - \sqrt{x+7}}{x-2} = \lim_{x \rightarrow 2} \frac{\sqrt{2x+5} - \sqrt{x+7}}{x-2} \cdot \frac{\sqrt{2x+5} + \sqrt{x+7}}{\sqrt{2x+5} + \sqrt{x+7}} \\ &= \lim_{x \rightarrow 2} \frac{(2x+5) - (x+7)}{(x-2)(\sqrt{2x+5} + \sqrt{x+7})} = \lim_{x \rightarrow 2} \frac{x-2}{(x-2)(\sqrt{2x+5} + \sqrt{x+7})} \\ &= \lim_{x \rightarrow 2} \frac{1}{\sqrt{2x+5} + \sqrt{x+7}} = \frac{1}{\sqrt{9} + \sqrt{9}} = \boxed{\frac{1}{6}}. \end{aligned}$$

87. Let

$$f(x) = \frac{x^2 - 6x - 16}{(x^2 - 7x - 8)\sqrt{x^2 - 4}} = \frac{(x-8)(x+2)}{(x-8)(x+1)\sqrt{x^2 - 4}}.$$

- (a) The function f is defined for all values x for which the denominator is not equal to zero and $x^2 - 4 > 0$. Thus, the domain of f is the set $\{x|x < -2\} \cup \{x|x > 2, x \neq 8\}$. Note that the condition $x \neq -1$ need not be explicitly included because -1 does not have an absolute value greater than 2, and so is already eliminated by virtue of this condition.
- (b) Because the function f is the product, quotient and composition of functions that are continuous on their domains, f is continuous on its domain. Thus, f is discontinuous at $x = 8$ and on the interval $[-2, 2]$.

(c) Because

$$\lim_{x \rightarrow 8} f(x) = \lim_{x \rightarrow 8} \frac{(x-8)(x+2)}{(x-8)(x+1)\sqrt{x^2-4}} = \lim_{x \rightarrow 8} \frac{(x+2)}{(x+1)\sqrt{x^2-4}} = \frac{10}{9\sqrt{60}} = \frac{5}{9\sqrt{15}}$$

exists, the discontinuity at $x = 8$ is removable.

88. (a) Because the function $f(x) = \sin x + x - 3$ is the sum of the sine function and a polynomial function, both of which are continuous on the set of all real numbers, f is continuous on the set of all real numbers and is therefore continuous on the closed interval $[0, \pi]$. Now, $f(0) = \sin 0 + 0 - 3 = -3 < 0$ and $f(\pi) = \sin \pi + \pi - 3 = \pi - 3 > 0$, so the Intermediate Value Theorem guarantees that f has a zero on the interval $(0, \pi)$.

(b) Using a TI-84 Plus calculator, the zero is $x \approx 2.180$, rounded to three decimal places.

89. (a) Because the function $f(x) = e^x + x - 2$ is the sum of an exponential function and a polynomial function, both of which are continuous on the set of all real numbers, f is continuous on the set of all real numbers and is therefore continuous on the closed interval $[0, 2]$. Now, $f(0) = e^0 + 0 - 2 = -1 < 0$ and $f(2) = e^2 + 2 - 2 = e^2 > 0$, so the Intermediate Value Theorem guarantees that f has a zero on the interval $(0, 2)$.

(b) Using a TI-84 Plus calculator, the zero is $x \approx 0.443$, rounded to three decimal places.

90. Answers will vary. The figure below displays the graph of a function that is continuous on $[5, 12]$, that is negative at both endpoints, and has exactly three zeros in the interval. This does not contradict the Intermediate Value Theorem, because the theorem provides no information about zeros of a function when the endpoint values are the same sign.

91. Answers will vary. The figure below displays the graph of a function that is continuous on $[-1, 2]$, that is positive at both endpoints, and has exactly two zeros in the interval. This does not contradict the Intermediate Value Theorem, because the theorem provides no information about zeros of a function when the endpoint values are the same sign.

92. Answers will vary. The figure below displays the graph of a function that is continuous on $[-2, 3]$, that is positive at -2 and negative at 3 , and has exactly two zeros in the interval. This does not contradict the Intermediate Value Theorem, because the theorem guarantees that the function has **at least** one zero on the interval $(-2, 3)$.

93. Answers will vary. The figure below displays the graph of a function that is continuous on $[-5, 0]$, that is negative at -5 and positive at 0 , and has exactly three zeros in the interval. This does not contradict the Intermediate Value Theorem, because the theorem guarantees that the function has **at least** one zero on the interval $(-5, 0)$.

94. (a) Although the function $f(x) = x^4 - 1$ is continuous on the closed interval $[-2, 2]$, $f(-2) = (-2)^4 - 1 = 15 > 0$ and $f(2) = 2^4 - 1 = 15 > 0$. Because the function has the same sign at both endpoints, the Intermediate Value Theorem gives no information about the zeros of f on the interval $(-2, 2)$.
- (b) The graph of f shown below indicates that f has two zeros on the interval $(-2, 2)$: one at $x = -1$, the other at $x = 1$.

95. (a) Although the function $f(x) = \ln(x^2 + 2)$ is continuous on the closed interval $[-2, 2]$, $f(-2) = \ln 6 > 0$ and $f(2) = \ln 6 > 0$. Because the function has the same sign at both endpoints, the Intermediate Value Theorem gives no information about the zeros of f on the interval $(-2, 2)$.
- (b) The graph of f shown below indicates that f has no zero on the interval $[-2, 2]$.

96. (a) If the graphs of the functions $y = x^3$ and $y = 1 - x^2$ intersect, then the x -coordinate of the point of intersection must be a solution of the equation $x^3 = 1 - x^2$, or $x^3 + x^2 - 1 = 0$. Let $f(x) = x^3 + x^2 - 1$. This function is continuous on the closed interval $[0, 1]$ with $f(0) = -1 < 0$ and $f(1) = 1 > 0$. The Intermediate Value Theorem therefore guarantees that f has a zero on the interval $(0, 1)$. Hence, the graphs of the functions $y = x^3$ and $y = 1 - x^2$ do intersect somewhere between $x = 0$ and $x = 1$.
- (b) Using a TI-84 Plus calculator, the point of intersection, rounded to three decimal places, is $(0.755, 0.430)$.
- (c) The figure below displays the graphs of both functions with the point of intersection labeled to three decimal places.

97. Let $v(t)$ denote the speed of the airplane as a function of time. Further, let t_1 denote a time when the speed of the airplane was 620 miles per hour, $t_2 > t_1$ denote a time when the speed of the airplane had slowed to 608 miles per hour, and $t_3 > t_2$ denote a time when the speed of the airplane had increased to 614 miles per hour. Now, consider the function $f(t) = v(t) - 610$. Assuming $v(t)$ is continuous for all t , f is also continuous for all t . Because

$$f(t_1) = v(t_1) - 610 = 620 - 610 = 10 > 0$$

and

$$f(t_2) = v(t_2) - 610 = 608 - 610 = -2 < 0,$$

the Intermediate Value Theorem guarantees that $f(t) = 0$, or $v(t) = 610$, for some time between t_1 and t_2 . Similarly,

$$f(t_2) = v(t_2) - 610 = 608 - 610 = -2 < 0$$

and

$$f(t_3) = v(t_3) - 610 = 614 - 610 = 4 > 0,$$

so the Intermediate Value Theorem guarantees that $f(t) = 0$, or $v(t) = 610$, for some time between t_2 and t_3 . Thus, the airplane's speed is 610 miles per hour on at least two different occasions during the flight.

98. Let f be a function that is defined and continuous on the closed interval $[a, b]$. The function

$$h(x) = \frac{1}{f(x)}$$

will therefore be continuous on the closed interval $[a, b]$, except for those values x at which $f(x) = 0$. Thus, if f is never zero on the closed interval $[a, b]$, then h will be continuous on the closed interval $[a, b]$.

99. (a) Factoring, $f(x) = x^3 - 3x^2 - 4x + 12 = (x - 3)(x^2 - 4) = (x - 3)(x - 2)(x + 2)$. Thus, the zeros of the function f are $x = -2$, $x = 2$, and $x = 3$.
- (b) The function h will be continuous at $x = 3$ provided $p = \lim_{x \rightarrow 3} h(x)$. Now,

$$\lim_{x \rightarrow 3} h(x) = \lim_{x \rightarrow 3} \frac{(x - 3)(x^2 - 4)}{x - 3} = \lim_{x \rightarrow 3} (x^2 - 4) = 5.$$

Therefore, h is continuous at $x = 3$ when $p = 5$.

- (c) With $p = 5$, the function h reduces to $x^2 - 4$ for all x . Because

$$h(-x) = (-x)^2 - 4 = x^2 - 4 = h(x),$$

$h(x)$ is an even function.

100. Consider the one-sided limits as x approaches 0:

$$\lim_{x \rightarrow 0^-} f(x) = \lim_{x \rightarrow 0^-} \frac{|x|}{x} = \lim_{x \rightarrow 0^-} \frac{-x}{x} = \lim_{x \rightarrow 0^-} -1 = -1$$

and

$$\lim_{x \rightarrow 0^+} f(x) = \lim_{x \rightarrow 0^+} \frac{|x|}{x} = \lim_{x \rightarrow 0^+} \frac{x}{x} = \lim_{x \rightarrow 0^+} 1 = 1.$$

Because the two one-sided limits as x approaches 0 are not equal, $\lim_{x \rightarrow 0} f(x)$ does not exist. Therefore, the discontinuity at $x = 0$ is not removable; e.g., it is impossible to define $f(0)$ so that f is continuous at $x = 0$.

101. Answers will vary. One possible response is the following. The polynomial functions $f(x) = x^2 - 1$ and $g(x) = x - 3$ are continuous at $c = 3$; however, because $g(3) = 0$, the function $\frac{f}{g}$ is not continuous at $c = 3$.

102. Answers will vary. One possible response is the following. A discontinuity at $x = c$ is removable when the limit as x approaches c exists but that limit is not equal to the function value at $x = c$; a discontinuity at $x = c$ is nonremovable when the limit as x approaches c does not exist. An example of a removable discontinuity is $x = 3$ for the function $f(x) = \frac{x^2 - 9}{x - 3}$. Because

$$\lim_{x \rightarrow 3} f(x) = \lim_{x \rightarrow 3} \frac{x^2 - 9}{x - 3} = \lim_{x \rightarrow 3} \frac{(x - 3)(x + 3)}{x - 3} = \lim_{x \rightarrow 3} (x + 3) = 6,$$

the discontinuity at $x = 3$ can be removed by defining $f(3) = 6$. An example of a nonremovable discontinuity is $x = 3$ for the function

$$g(x) = \begin{cases} x + 3, & x \leq 3 \\ 9 - x^2, & x > 3. \end{cases}$$

Here,

$$\lim_{x \rightarrow 3^-} g(x) = \lim_{x \rightarrow 3^-} (x + 3) = 6 \quad \text{but} \quad \lim_{x \rightarrow 3^+} g(x) = \lim_{x \rightarrow 3^+} (9 - x^2) = 0.$$

Because the two one-sided limits as x approaches 3 are not equal, $\lim_{x \rightarrow 3} g(x)$ does not exist.

103. Let $f(x) = x^3 + 3x - 5$, and note that $f(1) = -1 < 0$ and $f(2) = 9 > 0$. Set $m_1 = 1.5$, the midpoint of the interval $(1, 2)$, and then calculate $f(m_1) = f(1.5) = 2.875 > 0$. The sign of $f(1.5)$ is opposite that of $f(1)$, so the zero lies in the subinterval $(1, 1.5)$. Now repeat the process and set $m_2 = 1.25$, the midpoint of the interval $(1, 1.5)$. Next, calculate $f(m_2) = f(1.25) = 0.703125 > 0$. The sign of $f(1.25)$ is opposite that of $f(1)$, so the zero lies in the subinterval $(1, 1.25)$. Finally, set $m_3 = 1.125$, the midpoint of the interval $(1, 1.25)$, and calculate $f(m_3) = f(1.125) \approx -0.201172 < 0$. The sign of $f(1.125)$ is opposite that of $f(1.25)$, so the zero lies in the subinterval $(1.125, 1.25)$ and is given approximately by the midpoint of this subinterval $m_4 = 1.1875$.
104. Let $f(x) = x^3 - 4x + 2$, and note that $f(1) = -1 < 0$ and $f(2) = 2 > 0$. Set $m_1 = 1.5$, the midpoint of the interval $(1, 2)$, and then calculate $f(m_1) = f(1.5) = -0.625 < 0$. The sign of $f(1.5)$ is opposite that of $f(2)$, so the zero lies in the subinterval $(1.5, 2)$. Now repeat the process and set $m_2 = 1.75$, the midpoint of the interval $(1.5, 2)$. Next, calculate $f(m_2) = f(1.75) = 0.359375 > 0$. The sign of $f(1.75)$ is opposite that of $f(1.5)$, so the zero lies in the subinterval $(1.5, 1.75)$. Finally, set $m_3 = 1.625$, the midpoint of the interval $(1.5, 1.75)$, and calculate $f(m_3) = f(1.625) \approx -0.208984 < 0$. The sign of $f(1.625)$ is opposite that of $f(1.75)$, so the zero lies in the subinterval $(1.625, 1.75)$ and is given approximately by the midpoint of this subinterval $m_4 = 1.6875$.

105. Let $f(x) = 2x^3 + 3x^2 + 4x - 1$, and note that $f(0) = -1 < 0$ and $f(1) = 8 > 0$. Set $m_1 = 0.5$, the midpoint of the interval $(0, 1)$, and then calculate $f(m_1) = f(0.5) = 2 > 0$. The sign of $f(0.5)$ is opposite that of $f(0)$, so the zero lies in the subinterval $(0, 0.5)$. Now repeat the process and set $m_2 = 0.25$, the midpoint of the interval $(0, 0.5)$. Next, calculate $f(m_2) = f(0.25) = 0.21875 > 0$. The sign of $f(0.25)$ is opposite that of $f(0)$, so the zero lies in the subinterval $(0, 0.25)$. Finally, set $m_3 = 0.125$, the midpoint of the interval $(0, 0.25)$, and calculate $f(m_3) = f(0.125) \approx -0.449219 < 0$. The sign of $f(0.125)$ is opposite that of $f(0.25)$, so the zero lies in the subinterval $(0.125, 0.25)$ and is given approximately by the midpoint of this subinterval $m_4 = 0.1875$.
106. Let $f(x) = x^3 - x^2 - 2x + 1$, and note that $f(0) = 1 > 0$ and $f(1) = -1 < 0$. Set $m_1 = 0.5$, the midpoint of the interval $(0, 1)$, and then calculate $f(m_1) = f(0.5) = -0.125 < 0$. The sign of $f(0.5)$ is opposite that of $f(0)$, so the zero lies in the subinterval $(0, 0.5)$. Now repeat the process and set $m_2 = 0.25$, the midpoint of the interval $(0, 0.5)$. Next, calculate $f(m_2) = f(0.25) = 0.453125 > 0$. The sign of $f(0.25)$ is opposite that of $f(0.5)$, so the zero lies in the subinterval $(0.25, 0.5)$. Finally, set $m_3 = 0.375$, the midpoint of the interval $(0.25, 0.5)$, and calculate $f(m_3) = f(0.375) \approx 0.162109 > 0$. The sign of $f(0.375)$ is opposite that of $f(0.5)$, so the zero lies in the subinterval $(0.375, 0.5)$ and is given approximately by the midpoint of this subinterval $m_4 = 0.4375$.
107. Let $f(x) = x^3 - 6x - 12$, and note that $f(3) = -3 < 0$ and $f(4) = 28 > 0$. Set $m_1 = 3.5$, the midpoint of the interval $(3, 4)$, and then calculate $f(m_1) = f(3.5) = 9.875 > 0$. The sign of $f(3.5)$ is opposite that of $f(3)$, so the zero lies in the subinterval $(3, 3.5)$. Now repeat the process and set $m_2 = 3.25$, the midpoint of the interval $(3, 3.5)$. Next, calculate $f(m_2) = f(3.25) = 2.828125 > 0$. The sign of $f(3.25)$ is opposite that of $f(3)$, so the zero lies in the subinterval $(3, 3.25)$. Finally, set $m_3 = 3.125$, the midpoint of the interval $(3, 3.25)$, and calculate $f(m_3) = f(3.125) \approx -0.232422 < 0$. The sign of $f(3.125)$ is opposite that of $f(3.25)$, so the zero lies in the subinterval $(3.125, 3.25)$ and is given approximately by the midpoint of this subinterval $m_4 = 3.1875$.
108. Let $f(x) = 3x^3 + 5x - 40$, and note that $f(2) = -6 < 0$ and $f(3) = 56 > 0$. Set $m_1 = 2.5$, the midpoint of the interval $(2, 3)$, and then calculate $f(m_1) = f(2.5) = 19.375 > 0$. The sign of $f(2.5)$ is opposite that of $f(2)$, so the zero lies in the subinterval $(2, 2.5)$. Now repeat the process and set $m_2 = 2.25$, the midpoint of the interval $(2, 2.5)$. Next, calculate $f(m_2) = f(2.25) = 5.421875 > 0$. The sign of $f(2.25)$ is opposite that of $f(2)$, so the zero lies in the subinterval $(2, 2.25)$. Finally, set $m_3 = 2.125$, the midpoint of the interval $(2, 2.25)$, and calculate $f(m_3) = f(2.125) \approx -0.587891 < 0$. The sign of $f(2.125)$ is opposite that of $f(2.25)$, so the zero lies in the subinterval $(2.125, 2.25)$ and is given approximately by the midpoint of this subinterval $m_4 = 2.1875$.
109. Let $f(x) = x^4 - 2x^3 + 21x - 23$, and note that $f(1) = -3 < 0$ and $f(2) = 19 > 0$. Set $m_1 = 1.5$, the midpoint of the interval $(1, 2)$, and then calculate $f(m_1) = f(1.5) = 6.8125 > 0$. The sign of $f(1.5)$ is opposite that of $f(1)$, so the zero lies in the subinterval $(1, 1.5)$. Now repeat the process and set $m_2 = 1.25$, the midpoint of the interval $(1, 1.5)$. Next, calculate $f(m_2) = f(1.25) \approx 1.785156 > 0$. The sign of $f(1.25)$ is opposite that of $f(1)$, so the zero lies in the subinterval $(1, 1.25)$. Finally, set $m_3 = 1.125$, the midpoint of the interval $(1, 1.25)$, and calculate $f(m_3) = f(1.125) \approx -0.620850 < 0$. The sign of $f(1.125)$ is opposite that of $f(1.25)$, so the zero lies in the subinterval $(1.125, 1.25)$ and is given approximately by the midpoint of this subinterval $m_4 = 1.1875$.
110. Let $f(x) = x^4 - x^3 + x - 2$, and note that $f(1) = -1 < 0$ and $f(2) = 8 > 0$. Set $m_1 = 1.5$, the midpoint of the interval $(1, 2)$, and then calculate $f(m_1) = f(1.5) = 1.1875 > 0$. The sign of $f(1.5)$ is opposite that of $f(1)$, so the zero lies in the subinterval $(1, 1.5)$. Now repeat the process and set $m_2 = 1.25$, the midpoint of the interval $(1, 1.5)$. Next, calculate $f(m_2) = f(1.25) \approx -0.261719 < 0$. The sign of $f(1.25)$ is opposite that of $f(1.5)$, so the zero lies in the subinterval $(1.25, 1.5)$. Finally, set $m_3 = 1.375$, the midpoint of the interval $(1.25, 1.5)$, and calculate $f(m_3) = f(1.375) \approx 0.349854 > 0$. The sign of $f(1.375)$ is opposite that of $f(1.25)$, so the zero lies in the subinterval $(1.25, 1.375)$ and is given approximately by the midpoint of this subinterval $m_4 = 1.3125$.

111. The polynomial function $x^2 + 4x$ is continuous on the set of all real numbers and is non-negative on the set $\{x|x \leq -4\} \cup \{x|x \geq 0\}$. The function $f(x) = \sqrt{x^2 + 4x} - 2$ is therefore continuous on the set $\{x|x \leq -4\} \cup \{x|x \geq 0\}$, which contains the closed interval $[0, 1]$. Because $f(0) = \sqrt{0} - 2 = -2 < 0$ and $f(1) = \sqrt{5} - 2 \approx 0.236 > 0$, the Intermediate Value Theorem guarantees that f must have a zero on the interval $(0, 1)$.

To approximate this zero, subdivide the interval $[0, 1]$ into 10 subintervals, each of length 0.1, and evaluate f at each endpoint, looking for two successive function values with opposite signs. This yields $f(0.8) \approx -0.040408$ and $f(0.9) = 0.1$, indicating that the zero lies in the subinterval $(0.8, 0.9)$. Thus, correct to one decimal place, the zero is $\boxed{x = 0.8}$.

112. The polynomial function $f(x) = x^3 - x + 2$ is continuous for all real numbers, so it is continuous on the closed interval $[-2, 0]$. Because $f(-2) = (-2)^3 - (-2) + 2 = -4 < 0$ and $f(0) = 2 > 0$, the Intermediate Value Theorem guarantees that f must have a zero on the interval $(-2, 0)$.

To approximate this zero, subdivide the interval $[-2, 0]$ into 20 subintervals, each of length 0.1, and evaluate f at each endpoint, looking for two successive function values with opposite signs. This yields $f(-1.6) = -0.496$ and $f(-1.5) = 0.125$, indicating that the zero lies in the subinterval $(-1.6, -1.5)$. Next, subdivide the interval $[-1.6, -1.5]$ into 10 subintervals, each of length 0.01. The two successive function values that are of opposite sign are $f(-1.53) = -0.051577$ and $f(-1.52) = 0.008192$, so the zero has now been isolated to the interval $(-1.53, -1.52)$. Thus, correct to two decimal places, the zero is $\boxed{x = -1.52}$.

113. Let f and g be functions that are continuous at c . Then,

$$\lim_{x \rightarrow c} f(x) = f(c) \quad \text{and} \quad \lim_{x \rightarrow c} g(x) = g(c).$$

To prove that $f + g$ is continuous at c , it must be shown that $\lim_{x \rightarrow c} [f(x) + g(x)] = f(c) + g(c)$. Using the Limit of a Sum Property, it follows that

$$\lim_{x \rightarrow c} [f(x) + g(x)] = \lim_{x \rightarrow c} f(x) + \lim_{x \rightarrow c} g(x) = f(c) + g(c),$$

as required.

114. Let f and g be functions that are continuous on the closed interval $[a, b]$, with $f(a) < g(a)$ and $f(b) > g(b)$. Define the function $h(x) = f(x) - g(x)$. Because f and g are both continuous on $[a, b]$, it follows that h is also continuous on $[a, b]$. Now,

$$h(a) = f(a) - g(a) < 0 \quad \text{and} \quad h(b) = f(b) - g(b) > 0.$$

Thus, by the Intermediate Value Theorem, there is a number c between a and b such that $h(c) = f(c) - g(c) = 0$, or $f(c) = g(c)$. This implies that the graphs of $y = f(x)$ and $y = g(x)$ intersect at $x = c$; that is, the graphs intersect somewhere between $x = a$ and $x = b$.

Challenge Problems

115. Let $f(x) = \frac{1}{x-1} + \frac{1}{x-2}$. Because f is continuous on the interval $(1, 2)$, it is continuous on any closed interval contained within $(1, 2)$, say $[1.1, 1.9]$. With

$$f(1.1) = \frac{1}{1.1-1} + \frac{1}{1.1-2} = 10 - \frac{10}{9} = \frac{80}{9} > 0$$

and

$$f(1.9) = \frac{1}{1.9-1} + \frac{1}{1.9-2} = \frac{10}{9} - 10 = -\frac{80}{9} < 0,$$

the Intermediate value Theorem guarantees there exists a number c between 1.1 and 1.9, and hence between 1 and 2, such that $f(c) = 0$.

116. Let $f(x) = x^2 - 7$. This polynomial function is continuous on the closed interval $[2.64, 2.65]$. With

$$f(2.64) = 2.64^2 - 7 = -0.0304 < 0 \quad \text{and} \quad f(2.65) = 2.65^2 - 7 = 0.0225 > 0,$$

the Intermediate Value Theorem guarantees there exists a number c between 2.64 and 2.65 such that $f(c) = c^2 - 7 = 0$, or $c^2 = 7$.

117. Let f be a function for which $\lim_{h \rightarrow 0} \frac{f(a+h) - f(a)}{h}$ exists. Now, let $x = a + h$. Then, as h approaches 0, x approaches a , and

$$\lim_{h \rightarrow 0} \frac{f(a+h) - f(a)}{h} = \lim_{x \rightarrow a} \frac{f(x) - f(a)}{x - a}.$$

To prove that f is continuous at $x = a$, it must be shown that $\lim_{x \rightarrow a} f(x) = f(a)$. Because $f(a)$ is a constant, $\lim_{x \rightarrow a} f(a) = f(a)$ and

$$\lim_{x \rightarrow a} f(x) = f(a) \quad \text{is equivalent to} \quad \lim_{x \rightarrow a} [f(x) - f(a)] = 0.$$

Proceeding with this last limit, we find

$$\lim_{x \rightarrow a} [f(x) - f(a)] = \lim_{x \rightarrow a} \left[\frac{f(x) - f(a)}{x - a} \cdot (x - a) \right] = \lim_{x \rightarrow a} \frac{f(x) - f(a)}{x - a} \cdot \lim_{x \rightarrow a} (x - a) = \lim_{x \rightarrow a} \frac{f(x) - f(a)}{x - a} \cdot 0 = 0,$$

where, in going from the first line to the second line, we have used the fact that $\lim_{x \rightarrow a} \frac{f(x) - f(a)}{x - a}$ exists so the Limit of a Product property applies.

118. The rational function $\frac{x^2 + x - 2}{x - 1}$ is continuous on the set of all real numbers except $x = 1$, so f is continuous on the interval $(-\infty, 1)$. The function f is also continuous on the intervals $(1, 4)$ and $(4, \infty)$ because it is a polynomial on each of these intervals. At $x = 1$,

$$\lim_{x \rightarrow 1^-} f(x) = \lim_{x \rightarrow 1^-} \frac{x^2 + x - 2}{x - 1} = \lim_{x \rightarrow 1^-} \frac{(x - 1)(x + 2)}{x - 1} = \lim_{x \rightarrow 1^-} (x + 2) = 3$$

and

$$\lim_{x \rightarrow 1^+} f(x) = \lim_{x \rightarrow 1^+} B(x - C)^2 = B(1 - C)^2.$$

Then, at $x = 4$,

$$\lim_{x \rightarrow 4^-} f(x) = \lim_{x \rightarrow 4^-} B(x - C)^2 = B(4 - C)^2$$

and

$$\lim_{x \rightarrow 4^+} f(x) = \lim_{x \rightarrow 4^+} (2x - 8) = 0.$$

Therefore, for f to be continuous at $x = 1$ and at $x = 4$, the constants A , B , C , and D must satisfy the equations

$$A = 3, \quad B(1 - C)^2 = 3, \quad B(4 - C)^2 = 0, \quad D = 0.$$

The solution of these equations is $A = 3, B = \frac{1}{3}, C = 4$, and $D = 0$. The figure below displays a graph of f with these values for the constants.

119. Let f be a function that is continuous on the closed interval $[0, 1]$ and for which $0 \leq f(x) \leq 1$ for all x in $[0, 1]$. Define the function $g(x) = x - f(x)$. Because g is the difference between two functions that are continuous on $[0, 1]$, g is also continuous on $[0, 1]$. Now,

$$g(0) = 0 - f(0) \leq 0 \quad \text{and} \quad g(1) = 1 - f(1) \geq 0.$$

If either $g(0) = 0$ or $g(1) = 0$, then either $f(0) = 0$ or $f(1) = 1$ and a c in $[0, 1]$ has been found such that $f(c) = c$. Otherwise, $g(0) < 0$ and $g(1) > 0$, so that the Intermediate Value Theorem guarantees there exists a c in $(0, 1)$ such that $g(c) = 0$, or $f(c) = c$.

1.4: Limits and Continuity of Trigonometric, Exponential, and Logarithmic Functions

Concepts and Vocabulary

- $\lim_{x \rightarrow 0} \sin x = \sin 0 = \boxed{0}$.
- $\boxed{\text{False}}$. $\lim_{x \rightarrow 0} \frac{\cos x - 1}{x} = 0$.
- The Squeeze Theorem states that if functions f , g , and h have the property $f(x) \leq g(x) \leq h(x)$ for all x in an open interval containing c , except possibly at c , and if $\lim_{x \rightarrow c} f(x) = \lim_{x \rightarrow c} h(x) = L$, then $\lim_{x \rightarrow c} g(x) = \boxed{L}$.
- $\boxed{\text{False}}$. $f(x) = \csc x$ is continuous for all real numbers except $x = k\pi$, where k is any integer.

Skill Building

- Because $-x^2 + 1 \leq g(x) \leq x^2 + 1$ for all x in an open interval containing 0 and

$$\lim_{x \rightarrow 0} (-x^2 + 1) = 1 \quad \text{and} \quad \lim_{x \rightarrow 0} (x^2 + 1) = 1,$$

it follows from the Squeeze Theorem that $\lim_{x \rightarrow 0} g(x) = \boxed{1}$.

- Because $-(x - 2)^2 - 3 \leq g(x) \leq (x - 2)^2 - 3$ for all x in an open interval containing 2 and

$$\lim_{x \rightarrow 2} [-(x - 2)^2 - 3] = -3 \quad \text{and} \quad \lim_{x \rightarrow 2} [(x - 2)^2 - 3] = -3,$$

it follows from the Squeeze Theorem that $\lim_{x \rightarrow 2} g(x) = \boxed{-3}$.

- Because $\cos x \leq g(x) \leq 1$ for all x in an open interval containing 0 and

$$\lim_{x \rightarrow 0} \cos x = 1 \quad \text{and} \quad \lim_{x \rightarrow 0} 1 = 1,$$

it follows from the Squeeze Theorem that $\lim_{x \rightarrow 0} g(x) = \boxed{1}$.

- Because $-x^2 + 1 \leq g(x) \leq \sec x$ for all x in an open interval containing 0 and

$$\lim_{x \rightarrow 0} (-x^2 + 1) = 1 \quad \text{and} \quad \lim_{x \rightarrow 0} \sec x = 1,$$

it follows from the Squeeze Theorem that $\lim_{x \rightarrow 0} g(x) = \boxed{1}$.

- $\lim_{x \rightarrow 0} (x^3 + \sin x) = 0^3 + \sin 0 = 0 + 0 = \boxed{0}$.
- $\lim_{x \rightarrow 0} (x^2 - \cos x) = 0^2 - \cos 0 = 0 - 1 = \boxed{-1}$.
- $\lim_{x \rightarrow \pi/3} (\cos x + \sin x) = \cos \frac{\pi}{3} + \sin \frac{\pi}{3} = \boxed{\frac{\sqrt{3}}{2} + \frac{1}{2}}$.
- $\lim_{x \rightarrow \pi/3} (\sin x - \cos x) = \sin \frac{\pi}{3} - \cos \frac{\pi}{3} = \boxed{\frac{1}{2} - \frac{\sqrt{3}}{2}}$.

$$13. \lim_{x \rightarrow 0} \frac{\cos x}{1 + \sin x} = \frac{\cos 0}{1 + \sin 0} = \frac{1}{1 + 0} = \boxed{1}.$$

$$14. \lim_{x \rightarrow 0} \frac{\sin x}{1 + \cos x} = \frac{\sin 0}{1 + \cos 0} = \frac{0}{1 + 1} = \boxed{0}.$$

$$15. \lim_{x \rightarrow 0} \frac{3}{1 + e^x} = \frac{3}{1 + e^0} = \frac{3}{1 + 1} = \boxed{\frac{3}{2}}.$$

$$16. \lim_{x \rightarrow 0} \frac{e^x - 1}{1 + e^x} = \frac{e^0 - 1}{1 + e^0} = \frac{1 - 1}{1 + 1} = \boxed{0}.$$

$$17. \lim_{x \rightarrow 0} (e^x \sin x) = e^0 \sin 0 = 1(0) = \boxed{0}.$$

$$18. \lim_{x \rightarrow 0} (e^{-x} \tan x) = e^{-0} \tan 0 = 1(0) = \boxed{0}.$$

$$19. \lim_{x \rightarrow 1} \ln \left(\frac{e^x}{x} \right) = \ln \left(\frac{e^1}{1} \right) = \ln e = \boxed{1}.$$

$$20. \lim_{x \rightarrow 1} \ln \left(\frac{x}{e^x} \right) = \ln \left(\frac{1}{e^1} \right) = \ln e^{-1} = \boxed{-1}.$$

$$21. \lim_{x \rightarrow 0} \frac{e^{2x}}{1 + e^x} = \frac{e^{2(0)}}{1 + e^0} = \frac{1}{1 + 1} = \boxed{\frac{1}{2}}.$$

$$22. \lim_{x \rightarrow 0} \frac{1 - e^x}{1 - e^{2x}} = \lim_{x \rightarrow 0} \frac{1 - e^x}{(1 - e^x)(1 + e^x)} = \lim_{x \rightarrow 0} \frac{1}{1 + e^x} = \frac{1}{1 + e^0} = \frac{1}{1 + 1} = \boxed{\frac{1}{2}}.$$

$$23. \lim_{x \rightarrow 0} \frac{\sin(7x)}{x} = \lim_{x \rightarrow 0} \frac{7 \sin(7x)}{7x} = 7 \lim_{x \rightarrow 0} \frac{\sin(7x)}{7x} = 7(1) = \boxed{7}.$$

$$24. \lim_{x \rightarrow 0} \frac{\sin(\frac{x}{3})}{x} = \lim_{x \rightarrow 0} \frac{\frac{1}{3} \sin(\frac{x}{3})}{\frac{x}{3}} = \frac{1}{3} \lim_{x \rightarrow 0} \frac{\sin(\frac{x}{3})}{\frac{x}{3}} = \frac{1}{3}(1) = \boxed{\frac{1}{3}}.$$

$$25. \lim_{\theta \rightarrow 0} \frac{\theta + 3 \sin \theta}{2\theta} = \lim_{\theta \rightarrow 0} \frac{\theta}{2\theta} + \frac{3}{2} \lim_{\theta \rightarrow 0} \frac{\sin \theta}{\theta} = \frac{1}{2} + \frac{3}{2} = \boxed{2}.$$

$$26. \lim_{x \rightarrow 0} \frac{2x - 5 \sin(3x)}{x} = \lim_{x \rightarrow 0} \frac{2x}{x} - 5 \lim_{x \rightarrow 0} \frac{\sin(3x)}{x} = \lim_{x \rightarrow 0} 2 - 5 \lim_{x \rightarrow 0} \frac{\sin(3x)}{3x} = 2 - 15 = \boxed{-13}.$$

27. First note that

$$\lim_{\theta \rightarrow 0} \frac{\theta}{\sin \theta} = \lim_{\theta \rightarrow 0} \frac{1}{\frac{\sin \theta}{\theta}} = \frac{\lim_{\theta \rightarrow 0} 1}{\lim_{\theta \rightarrow 0} \frac{\sin \theta}{\theta}} = \frac{1}{1} = 1.$$

Then

$$\lim_{\theta \rightarrow 0} \frac{\sin \theta}{\theta + \tan \theta} = \lim_{\theta \rightarrow 0} \frac{1}{\frac{\theta}{\sin \theta} + \sec \theta} = \frac{1}{1 + 1} = \boxed{\frac{1}{2}}.$$

$$28. \lim_{\theta \rightarrow 0} \frac{\tan \theta}{\theta} = \lim_{\theta \rightarrow 0} \frac{\sin \theta}{\theta \cdot \cos \theta} = \lim_{\theta \rightarrow 0} \frac{\sin \theta}{\theta} \cdot \lim_{\theta \rightarrow 0} \frac{1}{\cos \theta} = 1 \cdot \frac{1}{1} = \boxed{1}.$$

$$29. \lim_{\theta \rightarrow 0} \frac{5}{\theta \cdot \csc \theta} = 5 \lim_{\theta \rightarrow 0} \frac{\sin \theta}{\theta} = 5(1) = \boxed{5}.$$

$$30. \lim_{\theta \rightarrow 0} \frac{\sin(3\theta)}{\sin(2\theta)} = \lim_{\theta \rightarrow 0} \frac{\frac{\sin(3\theta)}{\theta}}{\frac{\sin(2\theta)}{\theta}} = \frac{3 \lim_{\theta \rightarrow 0} \frac{\sin(3\theta)}{3\theta}}{2 \lim_{\theta \rightarrow 0} \frac{\sin(2\theta)}{2\theta}} = \frac{3(1)}{2(1)} = \boxed{\frac{3}{2}}.$$

$$31. \lim_{\theta \rightarrow 0} \frac{1 - \cos^2 \theta}{\theta} = \lim_{\theta \rightarrow 0} \frac{\sin^2 \theta}{\theta} = \lim_{\theta \rightarrow 0} \frac{\sin \theta}{\theta} \cdot \lim_{\theta \rightarrow 0} \sin \theta = 1(0) = \boxed{0}.$$

$$32. \lim_{\theta \rightarrow 0} \frac{\cos(4\theta) - 1}{2\theta} = \lim_{\theta \rightarrow 0} \frac{2[\cos(4\theta) - 1]}{4\theta} = 2 \lim_{\theta \rightarrow 0} \frac{\cos(4\theta) - 1}{4\theta} = 2(0) = \boxed{0}.$$

$$33. \lim_{\theta \rightarrow 0} (\theta \cdot \cot \theta) = \lim_{\theta \rightarrow 0} \frac{\theta \cdot \cos \theta}{\sin \theta} = \frac{\lim_{\theta \rightarrow 0} \cos \theta}{\lim_{\theta \rightarrow 0} \frac{\sin \theta}{\theta}} = \frac{1}{1} = \boxed{1}.$$

34. Because

$$\sin \theta \left(\frac{\cot \theta - \csc \theta}{\theta} \right) = \frac{\cos \theta - 1}{\theta},$$

it follows that

$$\lim_{\theta \rightarrow 0} \left[\sin \theta \left(\frac{\cot \theta - \csc \theta}{\theta} \right) \right] = \lim_{\theta \rightarrow 0} \frac{\cos \theta - 1}{\theta} = \boxed{0}.$$

35. First, f is defined at $c = 0$ with $f(0) = 3$. Next,

$$\lim_{x \rightarrow 0^-} f(x) = \lim_{x \rightarrow 0^-} (3 \cos x) = 3(1) = 3 \quad \text{and} \quad \lim_{x \rightarrow 0^+} f(x) = \lim_{x \rightarrow 0^+} (x + 3) = 3.$$

Because the two one-sided limits as x approaches 0 are equal to 3, it follows that $\lim_{x \rightarrow 0} f(x)$ exists and is equal to 3. Finally, $\lim_{x \rightarrow 0} f(x) = f(0)$, so $\boxed{f \text{ is continuous at } c = 0}$.

36. First, f is defined at $c = 0$ with $f(0) = 0$. Next,

$$\lim_{x \rightarrow 0^-} f(x) = \lim_{x \rightarrow 0^-} \cos x = \cos 0 = 1 \quad \text{and} \quad \lim_{x \rightarrow 0^+} f(x) = \lim_{x \rightarrow 0^+} e^x = e^0 = 1.$$

Because the two one-sided limits as x approaches 0 are equal to 1, it follows that $\lim_{x \rightarrow 0} f(x)$ exists and is equal to 1. However, $\lim_{x \rightarrow 0} f(x) \neq f(0)$, so $\boxed{f \text{ is not continuous at } c = 0}$.

37. First, f is defined at $c = \frac{\pi}{4}$ with $f\left(\frac{\pi}{4}\right) = \sin \frac{\pi}{4} = \frac{\sqrt{2}}{2}$. Next,

$$\lim_{x \rightarrow \pi/4^-} f(x) = \lim_{x \rightarrow \pi/4^-} \sin x = \sin \frac{\pi}{4} = \frac{\sqrt{2}}{2} \quad \text{and} \quad \lim_{x \rightarrow \pi/4^+} f(x) = \lim_{x \rightarrow \pi/4^+} \cos x = \cos \frac{\pi}{4} = \frac{\sqrt{2}}{2}.$$

Because the two one-sided limits as x approaches $\pi/4$ are equal to $\frac{\sqrt{2}}{2}$, it follows that $\lim_{x \rightarrow \pi/4} f(x)$ exists and is equal to $\frac{\sqrt{2}}{2}$. Finally, $\lim_{x \rightarrow \pi/4} f(x) = f\left(\frac{\pi}{4}\right)$, so $\boxed{f \text{ is continuous at } c = \frac{\pi}{4}}$.

38. First, f is defined at $c = 1$ with $f(1) = \ln 1 = 0$. Next,

$$\lim_{x \rightarrow 1^-} f(x) = \lim_{x \rightarrow 1^-} \tan^{-1} x = \tan^{-1} 1 = \frac{\pi}{4}$$

and

$$\lim_{x \rightarrow 1^+} f(x) = \lim_{x \rightarrow 1^+} \ln x = \ln 1 = 0.$$

Because the two one-sided limits as x approaches 0 are not equal, it follows that $\lim_{x \rightarrow 1} f(x)$ does not exist. Therefore, $\boxed{f \text{ is not continuous at } c = 1}$.

39. Let $g(x) = \sin x$ and $h(x) = \frac{x^2 - 4x}{x - 4}$. The trigonometric function g is continuous on the set of all real numbers, and the rational function h is continuous on the set $\{x|x \neq 4\}$. As the function f is the composition $g(h(x))$ and g is continuous at $h(x)$ for all x at which h is continuous, it follows that f is continuous on the set $\{x|x \neq 4\}$.
40. Let $g(x) = \cos x$ and $h(x) = \frac{x^2 - 5x + 1}{2x}$. The trigonometric function g is continuous on the set of all real numbers, and the rational function h is continuous on the set $\{x|x \neq 0\}$. As the function f is the composition $g(h(x))$ and g is continuous at $h(x)$ for all x at which h is continuous, it follows that f is continuous on the set $\{x|x \neq 0\}$.
41. The constant function 1 and the trigonometric function $\sin \theta$ are continuous on the set of all real numbers, so the sum of these functions, $1 + \sin \theta$, is also continuous on the set of all real numbers. Now, $1 + \sin \theta = 0$ when $\sin \theta = -1$. This happens for $\theta = \frac{3\pi}{2} + 2k\pi$, where k is any integer. Because f is the quotient of the constant function 1 and the function $1 + \sin \theta$, it follows that f is continuous on the set $\left\{x|x \neq \frac{3\pi}{2} + 2k\pi\right\}$, where k is any integer.
42. The constant function 1 and the trigonometric function $\cos \theta$ are continuous on the set of all real numbers. The function $\cos^2 \theta = \cos \theta \cdot \cos \theta$, being the product of continuous functions, and the function $1 + \cos^2 \theta$, being the sum of continuous functions, are then also continuous on the set of all real numbers. Finally, because $1 + \cos^2 \theta$ is never equal to zero for any real number θ and f is the quotient of the constant function 1 and the function $1 + \cos^2 \theta$, it follows that f is continuous on the set of all real numbers.
43. Let $g(x) = \ln x$ and $h(x) = x - 3$. The logarithmic function g is continuous on the set $\{x|x > 0\}$, and the polynomial function h is continuous on the set of all real numbers. As f is the quotient of the functions g and h and the only value x for which $h(x) = 0$ is $x = 3$, it follows that the function f is continuous on the set $\{x|x > 0, x \neq 3\}$.
44. Let $g(x) = \ln x$ and $h(x) = x^2 + 1$. The logarithmic function g is continuous on the set $\{x|x > 0\}$, and the polynomial function h is continuous on the set of all real numbers. As the function f is the composition $g(h(x))$ and g is continuous at $h(x)$ for all x because $x^2 + 1 \geq 1 > 0$ for any real number x , it follows that f is continuous on the set of all real numbers.
45. Let $g(x) = e^{-x}$ and $h(x) = \sin x$. The exponential function g and the trigonometric function h are both continuous on the set of all real numbers. As f is the product of g and h , it follows that f is also continuous on the set of all real numbers.
46. The exponential function e^x , the constant function 1, and the trigonometric function $\sin x$ are all continuous on the set of all real numbers. The function $\sin^2 x = \sin x \cdot \sin x$, being the product of continuous functions, and the function $1 + \sin^2 x$, being the sum of continuous functions, are then also continuous on the set of all real numbers. Finally, because $1 + \sin^2 x$ is never equal to zero for any real number x and f is the quotient of the exponential function e^x and the function $1 + \sin^2 x$, it follows that f is continuous on the set of all real numbers.

Applications and Extensions

47. Start from the compound inequality

$$-1 \leq \sin \left(\frac{1}{x} \right) \leq 1,$$

which holds for all $x \neq 0$. Multiplying by x^2 , which is non-negative for all x , then yields

$$-x^2 \leq x^2 \sin \left(\frac{1}{x} \right) \leq x^2.$$

As

$$\lim_{x \rightarrow 0} (-x^2) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} x^2 = 0,$$

it follows from the Squeeze Theorem that

$$\lim_{x \rightarrow 0} x^2 \sin\left(\frac{1}{x}\right) = \boxed{0}.$$

48. Start from the compound inequality

$$-1 \leq \cos\left(\frac{1}{x}\right) \leq 1,$$

which holds for all $x \neq 0$. Then

$$0 \leq 1 - \cos\left(\frac{1}{x}\right) \leq 2$$

and

$$\left|1 - \cos\left(\frac{1}{x}\right)\right| \leq 2.$$

Multiplying by $|x|$, which is non-negative for all x , then yields

$$|x| \left|1 - \cos\left(\frac{1}{x}\right)\right| = \left|x \left(1 - \cos\left(\frac{1}{x}\right)\right)\right| \leq 2|x|,$$

or

$$-2|x| \leq x \left(1 - \cos\left(\frac{1}{x}\right)\right) \leq 2|x|.$$

As

$$\lim_{x \rightarrow 0} (-2|x|) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} (2|x|) = 0,$$

it follows from the Squeeze Theorem that

$$\lim_{x \rightarrow 0} \left[x \left(1 - \cos\left(\frac{1}{x}\right)\right) \right] = \boxed{0}.$$

49. Start from the compound inequality

$$-1 \leq \cos\left(\frac{1}{x}\right) \leq 1,$$

which holds for all $x \neq 0$. Then

$$0 \leq 1 - \cos\left(\frac{1}{x}\right) \leq 2.$$

Multiplying by x^2 , which is non-negative for all x , then yields

$$0 \leq x^2 \left(1 - \cos\left(\frac{1}{x}\right)\right) \leq 2x^2.$$

As

$$\lim_{x \rightarrow 0} 0 = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} (2x^2) = 0,$$

it follows from the Squeeze Theorem that

$$\lim_{x \rightarrow 0} \left[x^2 \left(1 - \cos\left(\frac{1}{x}\right)\right) \right] = \boxed{0}.$$

50. First note that $x^3 + 3x^2 = x^2(x + 3)$ is non-negative for $x \geq -3$. Thus, as x approaches 0, $\sqrt{x^3 + 3x^2}$ is defined. Now, consider the compound inequality

$$-1 \leq \sin\left(\frac{1}{x}\right) \leq 1,$$

which holds for all $x \neq 0$. Multiplying by $\sqrt{x^3 + 3x^2}$, which is non-negative for all x , then yields

$$-\sqrt{x^3 + 3x^2} \leq \sqrt{x^3 + 3x^2} \sin\left(\frac{1}{x}\right) \leq \sqrt{x^3 + 3x^2}.$$

As

$$\lim_{x \rightarrow 0} (-\sqrt{x^3 + 3x^2}) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} \sqrt{x^3 + 3x^2} = 0,$$

it follows from the Squeeze Theorem that

$$\lim_{x \rightarrow 0} \sqrt{x^3 + 3x^2} \sin\left(\frac{1}{x}\right) = \boxed{0}.$$

$$51. \lim_{x \rightarrow 0} \frac{\sin(ax)}{\sin(bx)} = \lim_{x \rightarrow 0} \frac{\frac{\sin(ax)}{ax}}{\frac{\sin(bx)}{bx}} = \lim_{x \rightarrow 0} \frac{\frac{a \sin(ax)}{ax}}{\frac{b \sin(bx)}{bx}} = \frac{a}{b} \lim_{x \rightarrow 0} \frac{\frac{\sin(ax)}{ax}}{\frac{\sin(bx)}{bx}} = \frac{a}{b} \cdot \frac{1}{1} = \boxed{\frac{a}{b}}.$$

$$52. \lim_{x \rightarrow 0} \frac{\cos(ax)}{\cos(bx)} = \frac{\lim_{x \rightarrow 0} \cos(ax)}{\lim_{x \rightarrow 0} \cos(bx)} = \frac{1}{1} = \boxed{1}.$$

$$53. \lim_{x \rightarrow 0} \frac{\sin(ax)}{bx} = \lim_{x \rightarrow 0} \frac{a \sin(ax)}{abx} = \frac{a}{b} \lim_{x \rightarrow 0} \frac{\sin(ax)}{ax} = \frac{a}{b} \cdot 1 = \boxed{\frac{a}{b}}.$$

$$54. \lim_{x \rightarrow 0} \frac{1 - \cos(ax)}{bx} = \lim_{x \rightarrow 0} \frac{a(1 - \cos(ax))}{abx} = \frac{a}{b} \lim_{x \rightarrow 0} \frac{1 - \cos(ax)}{ax} = \frac{a}{b} \cdot 0 = \boxed{0}.$$

55. (a) Using the given functions $x(\theta)$ and $y(\theta)$,

$$\lim_{\theta \rightarrow \frac{\pi}{4}^+} x(\theta) = \lim_{\theta \rightarrow \frac{\pi}{4}^+} [(10 \cos \theta)t] = \left(10 \cos \frac{\pi}{4}\right)t = \boxed{5\sqrt{2}t},$$

and

$$\lim_{\theta \rightarrow \frac{\pi}{4}^+} y(\theta) = \lim_{\theta \rightarrow \frac{\pi}{4}^+} [-16t^2 + (10 \sin \theta)t] = -16t^2 + \left(10 \sin \frac{\pi}{4}\right)t = \boxed{-16t^2 + 5\sqrt{2}t}.$$

- (b) The limits from part (a) indicate that the object would immediately begin moving downward into the inclined plane. This is not consistent with what would be expected for the motion of an object propelled at an angle close to $\frac{\pi}{4}$; that is, propelled along the inclined plane.
- (c) Using the given functions $x(\theta)$ and $y(\theta)$,

$$\lim_{\theta \rightarrow \frac{\pi}{2}^-} x(\theta) = \lim_{\theta \rightarrow \frac{\pi}{2}^-} [(10 \cos \theta)t] = \left(10 \cos \frac{\pi}{2}\right)t = \boxed{0},$$

and

$$\lim_{\theta \rightarrow \frac{\pi}{2}^-} y(\theta) = \lim_{\theta \rightarrow \frac{\pi}{2}^-} [-16t^2 + (10 \sin \theta)t] = -16t^2 + \left(10 \sin \frac{\pi}{2}\right)t = \boxed{-16t^2 + 10t}.$$

- (d) The limits in part (c) indicate that the horizontal position remains at 0. The vertical position, given by $y = -16t^2 + 10t$, indicates that the object reaches a maximum height at $t = \frac{5}{16}$ seconds and returns to the ground after $t = \frac{5}{8}$ seconds. These conclusions are consistent with what would be expected for the motion of an object propelled close to the vertical.

56.

$$\begin{aligned}\lim_{x \rightarrow 0} \frac{1 - \cos x}{x^2} &= \lim_{x \rightarrow 0} \frac{1 - \cos x}{x^2} \cdot \frac{1 + \cos x}{1 + \cos x} = \lim_{x \rightarrow 0} \frac{1 - \cos^2 x}{x^2(1 + \cos x)} = \lim_{x \rightarrow 0} \frac{\sin^2 x}{x^2(1 + \cos x)} \\ &= \lim_{x \rightarrow 0} \frac{\sin x}{x} \cdot \lim_{x \rightarrow 0} \frac{\sin x}{x} \cdot \lim_{x \rightarrow 0} \frac{1}{1 + \cos x} = 1 \cdot 1 \cdot \frac{1}{1 + 1} = \frac{1}{2}.\end{aligned}$$

57. Let f be a function for which $0 \leq f(x) \leq 1$ for every x . Multiplying by x^2 , which is non-negative for all x , then yields $0 \leq x^2 f(x) \leq x^2$ for every x . As

$$\lim_{x \rightarrow 0} 0 = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} x^2 = 0,$$

it follows from the Squeeze Theorem that

$$\lim_{x \rightarrow 0} [x^2 f(x)] = 0.$$

58. Let f be a function for which $0 \leq f(x) \leq M$ for every x . Multiplying by x^2 , which is non-negative for all x , then yields $0 \leq x^2 f(x) \leq Mx^2$ for every x . As

$$\lim_{x \rightarrow 0} 0 = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} (Mx^2) = 0,$$

it follows from the Squeeze Theorem that

$$\lim_{x \rightarrow 0} [x^2 f(x)] = 0.$$

59. To make f continuous at 0, $f(0)$ should be defined equal to the value of $\lim_{x \rightarrow 0} f(x)$, provided this limit exists. Here,

$$\lim_{x \rightarrow 0} \frac{\sin(\pi x)}{x} = \lim_{x \rightarrow 0} \frac{\pi \sin(\pi x)}{\pi x} = \pi \lim_{x \rightarrow 0} \frac{\sin(\pi x)}{\pi x} = \pi \cdot 1 = \pi.$$

Thus, $f(0)$ should be set equal to π to make f continuous at 0.

60. The functions $\sin(\pi x)$ and $\frac{1}{x(1-x)}$ are both continuous on the open interval $(0, 1)$; consequently, the function $f(x) = \frac{\sin(\pi x)}{x(1-x)}$ is also continuous on the open interval $(0, 1)$. Now,

$$\lim_{x \rightarrow 0^+} f(x) = \lim_{x \rightarrow 0^+} \frac{\sin(\pi x)}{x(1-x)} = \lim_{x \rightarrow 0^+} \frac{\pi \sin(\pi x)}{\pi x(1-x)} = \pi \lim_{x \rightarrow 0^+} \frac{\sin(\pi x)}{\pi x} \cdot \lim_{x \rightarrow 0^+} \frac{1}{1-x} = \pi \cdot 1 \cdot \frac{1}{1-0} = \pi,$$

and, using the identity $\sin \theta = \sin(\pi - \theta)$,

$$\lim_{x \rightarrow 1^-} f(x) = \lim_{x \rightarrow 1^-} \frac{\sin(\pi x)}{x(1-x)} = \lim_{x \rightarrow 1^-} \frac{\pi \sin(\pi(1-x))}{\pi x(1-x)} = \pi \lim_{x \rightarrow 1^-} \frac{\sin(\pi(1-x))}{\pi(1-x)} \cdot \lim_{x \rightarrow 1^-} \frac{1}{x} = \pi \cdot 1 \cdot \frac{1}{1} = \pi.$$

Thus, defining $f(0) = f(1) = \pi$, f will be continuous on the closed interval $[0, 1]$.

61. Because

$$\lim_{x \rightarrow 0} f(x) = \lim_{x \rightarrow 0} \frac{\sin x}{x} = 1 = f(0),$$

f is continuous at 0.

62. Because

$$\lim_{x \rightarrow 0} f(x) = \lim_{x \rightarrow 0} \frac{1 - \cos x}{x} = 0 = f(0),$$

f is continuous at 0.

63. Let n be a positive integer, and start from the inequality

$$\left| \sin \left(\frac{1}{x} \right) \right| \leq 1,$$

which holds for all $x \neq 0$. Multiplying by $|x^n|$, which is non-negative for all x , then yields

$$|x^n| \cdot \left| \sin \left(\frac{1}{x} \right) \right| = \left| x^n \sin \left(\frac{1}{x} \right) \right| \leq |x^n|,$$

or

$$-|x^n| \leq x^n \sin \left(\frac{1}{x} \right) \leq |x^n|.$$

As

$$\lim_{x \rightarrow 0} (-|x^n|) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} |x^n| = 0,$$

it follows from the Squeeze Theorem that

$$\lim_{x \rightarrow 0} \left[x^n \sin \left(\frac{1}{x} \right) \right] = 0.$$

64. Let $0 < \theta < \frac{\pi}{2}$. Consider the diagram presented in the problem statement. The length of the segment $\overline{PB}$ is shorter than the length of the segment $\overline{PA}$ because $\overline{PA}$ is the hypotenuse of the right triangle PBA for which $\overline{PB}$ is one of the legs. Moreover, the length of the segment $\overline{PA}$ is shorter than the length of the arc PA because the shortest distance between any two distinct points is the length of the line segment connecting the two points. Thus, the segment joining the points P and B is shorter than the length of the arc AP along the circle. As the length of the segment joining P and B is $\sin \theta$ while the length of the arc AP is θ , it follows that $\sin \theta \leq \theta$. Because θ is a first quadrant angle, it is also true that $\sin \theta \geq 0$. Thus

$$0 \leq \sin \theta \leq \theta.$$

With

$$\lim_{\theta \rightarrow 0^+} 0 = 0 \quad \text{and} \quad \lim_{\theta \rightarrow 0^+} \theta = 0,$$

it follows from the Squeeze Theorem that

$$\lim_{\theta \rightarrow 0^+} \sin \theta = 0.$$

If, instead, $-\frac{\pi}{2} < \theta < 0$, then the length of the segment joining P and B is $-\sin \theta$, so that

$$0 \leq -\sin \theta \leq \theta \quad \text{or} \quad -\theta \leq \sin \theta \leq 0.$$

With

$$\lim_{\theta \rightarrow 0^-} (-\theta) = 0 \quad \text{and} \quad \lim_{\theta \rightarrow 0^-} 0 = 0,$$

it follows from the Squeeze Theorem that

$$\lim_{\theta \rightarrow 0^-} \sin \theta = 0.$$

Finally, because the two one-sided limits are equal,

$$\lim_{\theta \rightarrow 0} \sin \theta = 0.$$

65. From the Pythagorean identity $\cos^2 \theta + \sin^2 \theta = 1$ it follows that $\cos \theta = \pm \sqrt{1 - \sin^2 \theta}$. In the limit as θ approaches 0, θ will eventually lie in the interval $(-\frac{\pi}{2}, \frac{\pi}{2})$, so that $\cos \theta$ will be positive; hence, $\cos \theta = \sqrt{1 - \sin^2 \theta}$. Therefore,

$$\lim_{\theta \rightarrow 0} \cos \theta = \lim_{\theta \rightarrow 0} \sqrt{1 - \sin^2 \theta} = \sqrt{1 - 0^2} = 1.$$

66. The function $\cos \theta$ is continuous on the set of all real numbers, and the polynomial function $5x^3 + 2x^2 - 8x + 1$ is also continuous on the set of all real numbers. As $f(x) = \cos(5x^3 + 2x^2 - 8x + 1)$ is the composition of the two previously mentioned functions, it follows that f is continuous on the set of all real numbers.
67. Answers will vary. One possible response is the following. Suppose we wish to evaluate $\lim_{x \rightarrow c} g(x)$ for some function g . If two functions f and h can be found such that $f(x) \leq g(x) \leq h(x)$ for all x in a neighborhood of c , except possibly at c , and $\lim_{x \rightarrow c} f(x) = \lim_{x \rightarrow c} h(x) = L$ for some real number L , then $\lim_{x \rightarrow c} g(x) = L$. In plain terms, the functions f and h squeeze the value of g toward L . A graph to illustrate the process is shown below.

Challenge Problems

68. To show that the sine function is continuous on its domain, it must be established that $\lim_{\theta \rightarrow c} \sin \theta = \sin c$ for any real number c . So let c be any real number. Then

$$\begin{aligned} \lim_{\theta \rightarrow c} \sin \theta &= \lim_{x \rightarrow 0} \sin(x + c) = \lim_{x \rightarrow 0} [\sin x \cos c + \cos x \sin c] \\ &= \cos c \lim_{x \rightarrow 0} \sin x + \sin c \lim_{x \rightarrow 0} \cos x = \cos c \cdot 0 + \sin c \cdot 1 = \sin c. \end{aligned}$$

Similarly, to show that the cosine function is continuous on its domain, it must be established that $\lim_{\theta \rightarrow c} \cos \theta = \cos c$ for any real number c . So let c be any real number. Then

$$\begin{aligned} \lim_{\theta \rightarrow c} \cos \theta &= \lim_{x \rightarrow 0} \cos(x + c) = \lim_{x \rightarrow 0} [\cos x \cos c - \sin x \sin c] \\ &= \cos c \lim_{x \rightarrow 0} \cos x - \sin c \lim_{x \rightarrow 0} \sin x = \cos c \cdot 1 - \sin c \cdot 0 = \cos c. \end{aligned}$$

69. $\lim_{x \rightarrow 0} \frac{\sin x^2}{x} = \lim_{x \rightarrow 0} \frac{x \sin x^2}{x^2} = \lim_{x \rightarrow 0} x \cdot \lim_{x \rightarrow 0} \frac{\sin x^2}{x^2} = 0(1) = \boxed{0}.$

70. As defined, $0 \leq f(x) \leq 1$ for all x , so that $|f(x)| \leq 1$. Multiplying this last inequality by $|x|$, which is non-negative for all x , yields

$$|x| \cdot |f(x)| = |xf(x)| \leq |x|, \quad \text{or} \quad -|x| \leq xf(x) \leq |x|.$$

Because

$$\lim_{x \rightarrow 0} (-|x|) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} |x| = 0,$$

it follows from the Squeeze Theorem that

$$\lim_{x \rightarrow 0} [xf(x)] = 0.$$

71. Using the diagram in the problem statement, let d denote the x -coordinate of the point D . Applying right angle trigonometry to the triangle ACD yields $d \tan \theta$ as the length of the segment $\overline{CD}$, while applying right angle trigonometry to the triangle BCD yields $(1 - d) \tan(n\theta)$ as the length of the segment $\overline{CD}$. Thus,

$$d \tan \theta = (1 - d) \tan(n\theta),$$

or

$$d = \frac{\tan(n\theta)}{\tan \theta + \tan(n\theta)} = \frac{\frac{\tan(n\theta)}{\tan \theta}}{1 + \frac{\tan(n\theta)}{\tan \theta}}.$$

Now,

$$\lim_{\theta \rightarrow 0} \frac{\tan(n\theta)}{\tan \theta} = \lim_{\theta \rightarrow 0} \frac{\sin(n\theta)}{\sin \theta} \cdot \frac{\cos \theta}{\cos(n\theta)} = \lim_{\theta \rightarrow 0} \frac{\sin(n\theta)}{\sin \theta} \cdot \lim_{\theta \rightarrow 0} \frac{\cos \theta}{\cos(n\theta)} = n(1) = n,$$

using the results of Problems 51 and 52. Thus, as θ approaches 0, $d \rightarrow \frac{n}{n+1}$, and the limiting position

of D is the point $\boxed{\left(\frac{n}{n+1}, 0\right)}$.

1.5: Infinite Limits; Limits at Infinity; Asymptotes

Concepts and Vocabulary

1. False. ∞ is **not** a number; ∞ is a symbol to represent the concept of becoming unbounded.
2. (a) $\lim_{x \rightarrow 0^-} \frac{1}{x} = \boxed{-\infty}$.
 (b) $\lim_{x \rightarrow 0^+} \frac{1}{x} = \boxed{\infty}$.
 (c) $\lim_{x \rightarrow 0^+} \ln x = \boxed{-\infty}$.
3. False. The graph of a rational function **may have** a vertical asymptote at **a** number x at which the function is undefined. The graph will have a vertical asymptote provided that at least one of the one-sided limits at that number is infinite. If neither of the one-sided limits is infinite, the graph will have a hole.
4. If $\lim_{x \rightarrow 4} f(x) = \infty$, then the line $x = 4$ is a vertical asymptote of the graph of f .
5. (a) $\lim_{x \rightarrow \infty} \frac{1}{x} = \boxed{0}$.
 (b) $\lim_{x \rightarrow \infty} \frac{1}{x^2} = \boxed{0}$.
 (c) $\lim_{x \rightarrow \infty} \ln x = \boxed{\infty}$.
6. False. $\lim_{x \rightarrow -\infty} 5 = 5$.
7. (a) $\lim_{x \rightarrow -\infty} e^x = \boxed{0}$.
 (b) $\lim_{x \rightarrow \infty} e^x = \boxed{\infty}$.
 (c) $\lim_{x \rightarrow \infty} e^{-x} = \boxed{0}$.
8. True. The graph of a function can have at most two horizontal asymptotes.

Skill Building

9. As x becomes unbounded in the positive direction, the graph of f approaches the line $y = 2$. Thus,
 $\lim_{x \rightarrow \infty} f(x) = 2$.
10. As x becomes unbounded in the negative direction, the graph of f approaches the line $y = 0$. Thus,
 $\lim_{x \rightarrow -\infty} f(x) = 0$.
11. As x approaches -1 from the left, the graph of f becomes unbounded in the positive direction. Thus,
 $\lim_{x \rightarrow -1^-} f(x) = \infty$.
12. As x approaches -1 from the right, the graph of f becomes unbounded in the positive direction. Thus,
 $\lim_{x \rightarrow -1^+} f(x) = \infty$.
13. As x approaches 3 from the left, the graph of f becomes unbounded in the positive direction. Thus,
 $\lim_{x \rightarrow 3^-} f(x) = \infty$.

14. As x approaches 3 from the right, the graph of f becomes unbounded in the positive direction. Thus,

$$\lim_{x \rightarrow 3^+} f(x) = \infty.$$

15. The graph of f has two vertical asymptotes: $x = -1$ and $x = 3$.

16. The graph of f has two horizontal asymptotes: $y = 0$ and $y = 2$.

17. As x becomes unbounded in the positive direction, the graph of f approaches the line $y = -3$. Thus,

$$\lim_{x \rightarrow \infty} f(x) = -3.$$

18. As x becomes unbounded in the negative direction, the graph of f approaches the line $y = 0$. Thus,

$$\lim_{x \rightarrow -\infty} f(x) = 0.$$

19. As x approaches -3 from the left, the graph of f becomes unbounded in the positive direction. Thus,

$$\lim_{x \rightarrow -3^-} f(x) = \infty.$$

20. As x approaches -3 from the right, the graph of f becomes unbounded in the negative direction. Thus,

$$\lim_{x \rightarrow -3^+} f(x) = -\infty.$$

21. As x approaches 0 from the left, the graph of f approaches the origin. Thus, $\lim_{x \rightarrow 0^-} f(x) = 0$.

22. As x approaches 0 from the right, the graph of f becomes unbounded in the positive direction. Thus,

$$\lim_{x \rightarrow 0^+} f(x) = \infty.$$

23. As x approaches 4 from the left, the graph of f becomes unbounded in the positive direction. Thus,

$$\lim_{x \rightarrow 4^-} f(x) = \infty.$$

24. As x approaches 4 from the right, the graph of f becomes unbounded in the positive direction. Thus,

$$\lim_{x \rightarrow 4^+} f(x) = \infty.$$

25. The graph of f has three vertical asymptotes: $x = -3$, $x = 0$, and $x = 4$.

26. The graph of f has two horizontal asymptotes: $y = 0$ and $y = -3$.

27. As x approaches 2 from the left, $3x$ approaches 6 and $x - 2$ approaches 0 from the left. Therefore, the ratio $\frac{3x}{x-2}$ becomes unbounded in the negative direction, so

$$\lim_{x \rightarrow 2^-} \frac{3x}{x-2} = -\infty.$$

The values in the table below support this conclusion.

x	1.9	1.99	1.999	$\rightarrow 2$
$f(x) = \frac{3x}{x-2}$	-57	-597	-5997	$f(x)$ approaches $-\infty$

28. As x approaches -4 from the right, $2x + 1$ approaches -7 and $x + 4$ approaches 0 from the right. Therefore, the ratio $\frac{2x+1}{x+4}$ becomes unbounded in the negative direction, so

$$\lim_{x \rightarrow -4^+} \frac{2x+1}{x+4} = -\infty.$$

The values in the table below support this conclusion.

x	$-4 \leftarrow$	-3.999	-3.99	-3.9
$f(x) = \frac{2x+1}{x+4}$	$f(x)$ approaches $-\infty$	-6998	-698	-68

29. As x approaches 2 from the right, 5 approaches 5 and $x^2 - 4$ approaches 0 from the right. Therefore, the ratio $\frac{5}{x^2-4}$ becomes unbounded in the positive direction, so

$$\lim_{x \rightarrow 2^+} \frac{5}{x^2 - 4} = \boxed{\infty}.$$

The values in the table below, which have been rounded to two decimal places, support this conclusion.

x	$2 \leftarrow$	2.001	2.01	2.1
$f(x) = \frac{5}{x^2-4}$	$f(x)$ approaches ∞	1249.69	124.69	12.20

30. As x approaches 1 from the left, $2x$ approaches 2 and $x^3 - 1$ approaches 0 from the left. Therefore, the ratio $\frac{2x}{x^3-1}$ becomes unbounded in the negative direction, so

$$\lim_{x \rightarrow 1^-} \frac{2x}{x^3 - 1} = \boxed{-\infty}.$$

The values in the table below, which have been rounded to two decimal places, support this conclusion.

x	0.9	0.99	0.999	$\rightarrow 1$
$f(x) = \frac{2x}{x^3-1}$	-6.64	-66.66	-666.67	$f(x)$ approaches $-\infty$

31. As x approaches -1 from the right, $5x + 3$ approaches -2 and $x(x + 1)$ approaches 0 from the left. Therefore, the ratio $\frac{5x+3}{x(x+1)}$ becomes unbounded in the positive direction, so

$$\lim_{x \rightarrow -1^+} \frac{5x + 3}{x(x + 1)} = \boxed{\infty}.$$

The values in the table below, which have been rounded to two decimal places, support this conclusion.

x	$-1 \leftarrow$	-0.999	-0.99	-0.9
$f(x) = \frac{5x+3}{x(x+1)}$	$f(x)$ approaches ∞	1997.00	196.97	16.67

32. As x approaches 0 from the left, $5x + 3$ approaches 3 and $5x(x - 1)$ approaches 0 from the right. Therefore, the ratio $\frac{5x+3}{5x(x-1)}$ becomes unbounded in the positive direction, so

$$\lim_{x \rightarrow 0^-} \frac{5x + 3}{5x(x - 1)} = \boxed{\infty}.$$

The values in the table below, which have been rounded to two decimal places, support this conclusion.

x	-0.1	-0.01	-0.001	$\rightarrow 0$
$f(x) = \frac{5x+3}{5x(x-1)}$	4.55	58.42	598.40	$f(x)$ approaches ∞

33. As x approaches -3 from the left, 1 approaches 1 and $x^2 - 9$ approaches 0 from the right. Therefore, the ratio $\frac{1}{x^2-9}$ becomes unbounded in the positive direction, so

$$\lim_{x \rightarrow -3^-} \frac{1}{x^2 - 9} = \boxed{\infty}.$$

The values in the table below, which have been rounded to two decimal places, support this conclusion.

x	-3.1	-3.01	-3.001	$\rightarrow -3$
$f(x) = \frac{1}{x^2 - 9}$	1.64	16.64	166.64	$f(x)$ approaches ∞

34. As x approaches 2 from the right, x approaches 2 and $x^2 - 4$ approaches 0 from the right. Therefore, the ratio $\frac{x}{x^2-4}$ becomes unbounded in the positive direction, so

$$\lim_{x \rightarrow 2^+} \frac{x}{x^2 - 4} = \boxed{\infty}.$$

The values in the table below, which have been rounded to two decimal places, support this conclusion.

x	$2 \leftarrow$	2.001	2.01	2.1
$f(x) = \frac{x}{x^2 - 4}$	$f(x)$ approaches ∞	500.12	50.12	5.12

35. As x approaches 3 , $1 - x$ approaches -2 and $(3 - x)^2$ approaches 0 from the right. Therefore, the ratio $\frac{1-x}{(3-x)^2}$ becomes unbounded in the negative direction, so

$$\lim_{x \rightarrow 3} \frac{1 - x}{(3 - x)^2} = \boxed{-\infty}.$$

The values in the table below support this conclusion.

x	2.9	2.99	2.999	$\rightarrow 3 \leftarrow$	3.001	3.01	3.1
$f(x) = \frac{1-x}{(3-x)^2}$	-190	-19900	-1999000	$f(x)$ approaches $-\infty$	-2001000	-20100	-210

36. As x approaches -1 , $x + 2$ approaches 1 and $(x + 1)^2$ approaches 0 from the right. Therefore, the ratio $\frac{x+2}{(x+1)^2}$ becomes unbounded in the positive direction, so

$$\lim_{x \rightarrow -1} \frac{x + 2}{(x + 1)^2} = \boxed{\infty}.$$

The values in the table below support this conclusion.

x	-1.1	-1.01	-1.001	$\rightarrow -1 \leftarrow$	-0.999	-0.99	-0.9
$f(x) = \frac{x+2}{(x+1)^2}$	90	9900	999000	$f(x)$ approaches ∞	1001000	10100	110

37. As x approaches π from the left, $\cos x$ approaches -1 and $\sin x$ approaches 0 from the right. Therefore, the ratio $\frac{\cos x}{\sin x} = \cot x$ becomes unbounded in the negative direction, so

$$\lim_{x \rightarrow \pi^-} \cot x = \boxed{-\infty}.$$

The values in the table below, which have been rounded to two decimal places, support this conclusion.

x	$\pi - 0.1$	$\pi - 0.01$	$\pi - 0.001$	$\rightarrow \pi$
$f(x) = \cot x$	-9.97	-100.00	-1000.00	$f(x)$ approaches $-\infty$

38. As x approaches $-\pi/2$ from the left, $\sin x$ approaches -1 and $\cos x$ approaches 0 from the left. Therefore, the ratio $\frac{\sin x}{\cos x} = \tan x$ becomes unbounded in the positive direction, so

$$\lim_{x \rightarrow -\pi/2^-} \tan x = \boxed{\infty}.$$

The values in the table below, which have been rounded to two decimal places, support this conclusion.

x	$-\frac{\pi}{2} - 0.1$	$-\frac{\pi}{2} - 0.01$	$-\frac{\pi}{2} - 0.001$	$\rightarrow -\pi/2$
$f(x) = \tan x$	9.97	100.00	1000.00	$f(x)$ approaches ∞

39. As x approaches $\pi/2$ from the right, $2x$ approaches π from the right, so $\sin(2x)$ approaches 0 from the left. Therefore, the ratio $\frac{1}{\sin(2x)} = \csc(2x)$ becomes unbounded in the negative direction, so

$$\lim_{x \rightarrow \pi/2^+} \csc(2x) = \boxed{-\infty}.$$

The values in the table below, which have been rounded to two decimal places, support this conclusion.

x	$\frac{\pi}{2} \leftarrow$	$\frac{\pi}{2} + 0.001$	$\frac{\pi}{2} + 0.01$	$\frac{\pi}{2} + 0.1$
$f(x) = \csc(2x)$	$f(x)$ approaches $-\infty$	-500.00	-50.00	-5.03

40. As x approaches $-\pi/2$ from the left, $\cos x$ approaches 0 from the left. Therefore, the ratio $\frac{1}{\cos x} = \sec x$ becomes unbounded in the negative direction, so

$$\lim_{x \rightarrow -\pi/2^-} \sec x = \boxed{-\infty}.$$

The values in the table below, which have been rounded to two decimal places, support this conclusion.

x	$-\frac{\pi}{2} - 0.1$	$-\frac{\pi}{2} - 0.01$	$-\frac{\pi}{2} - 0.001$	$\rightarrow -\pi/2$
$f(x) = \sec x$	-10.02	-100.00	-1000.00	$f(x)$ approaches $-\infty$

41. As x approaches -1 from the right, $x + 1$ approaches 0 from the right. Therefore, $\ln(x + 1)$ becomes unbounded in the negative direction, so

$$\lim_{x \rightarrow -1^+} \ln(x + 1) = \boxed{-\infty}.$$

The values in the table below, which have been rounded to two decimal places, support this conclusion.

x	$-1 \leftarrow$	$-1 + 10^{-6}$	$-1 + 10^{-4}$	$-1 + 10^{-2}$
$f(x) = \ln(x + 1)$	$f(x)$ approaches $-\infty$	-13.82	-9.21	-4.61

42. As x approaches 1 from the right, $x - 1$ approaches 0 from the right. Therefore, $\ln(x - 1)$ becomes unbounded in the negative direction, so

$$\lim_{x \rightarrow 1^+} \ln(x - 1) = \boxed{-\infty}.$$

The values in the table below, which have been rounded to two decimal places, support this conclusion.

x	$1 \leftarrow$	$1 + 10^{-6}$	$1 + 10^{-4}$	$1 + 10^{-2}$
$f(x) = \ln(x - 1)$	$f(x)$ approaches $-\infty$	-13.82	-9.21	-4.61

$$43. \lim_{x \rightarrow \infty} \frac{5}{x^2 + 4} = \lim_{x \rightarrow \infty} \frac{\frac{5}{x^2}}{\frac{x^2 + 4}{x^2}} = \lim_{x \rightarrow \infty} \frac{\frac{5}{x^2}}{1 + \frac{4}{x^2}} = \frac{0}{1 + 0} = \boxed{0}.$$

$$44. \lim_{x \rightarrow -\infty} \frac{1}{x^2 - 9} = \lim_{x \rightarrow -\infty} \frac{\frac{1}{x^2}}{\frac{x^2 - 9}{x^2}} = \lim_{x \rightarrow -\infty} \frac{\frac{1}{x^2}}{1 - \frac{9}{x^2}} = \frac{0}{1 - 0} = \boxed{0}.$$

$$45. \lim_{x \rightarrow \infty} \frac{2x + 4}{5x} = \lim_{x \rightarrow \infty} \frac{\frac{2x + 4}{5x}}{\frac{5x}{5x}} = \lim_{x \rightarrow \infty} \frac{\frac{2}{5} + \frac{4}{5x}}{1} = \frac{\frac{2}{5} + 0}{1} = \boxed{\frac{2}{5}}.$$

$$46. \lim_{x \rightarrow \infty} \frac{x + 1}{x} = \lim_{x \rightarrow \infty} \frac{\frac{x + 1}{x}}{\frac{x}{x}} = \lim_{x \rightarrow \infty} \frac{1 + \frac{1}{x}}{1} = \frac{1 + 0}{1} = \boxed{1}.$$

$$47. \lim_{x \rightarrow \infty} \frac{x^3 + x^2 + 2x - 1}{x^3 + x + 1} = \lim_{x \rightarrow \infty} \frac{\frac{x^3 + x^2 + 2x - 1}{x^3}}{\frac{x^3 + x + 1}{x^3}} = \lim_{x \rightarrow \infty} \frac{1 + \frac{1}{x} + \frac{2}{x^2} - \frac{1}{x^3}}{1 + \frac{1}{x^2} + \frac{1}{x^3}} = \frac{1 + 0 + 0 - 0}{1 + 0 + 0} = \boxed{1}.$$

$$48. \lim_{x \rightarrow \infty} \frac{2x^2 - 5x + 2}{5x^2 + 7x - 1} = \lim_{x \rightarrow \infty} \frac{\frac{2x^2 - 5x + 2}{5x^2}}{\frac{5x^2 + 7x - 1}{5x^2}} = \lim_{x \rightarrow \infty} \frac{\frac{2}{5} - \frac{1}{x} + \frac{2}{5x^2}}{1 + \frac{7}{5x} - \frac{1}{5x^2}} = \frac{\frac{2}{5} - 0 + 0}{1 + 0 - 0} = \boxed{\frac{2}{5}}.$$

$$49. \lim_{x \rightarrow -\infty} \frac{x^2 + 1}{x^3 - 1} = \lim_{x \rightarrow -\infty} \frac{\frac{x^2 + 1}{x^3}}{\frac{x^3 - 1}{x^3}} = \lim_{x \rightarrow -\infty} \frac{\frac{1}{x} + \frac{1}{x^3}}{1 - \frac{1}{x^3}} = \frac{0 + 0}{1 - 0} = \boxed{0}.$$

$$50. \lim_{x \rightarrow \infty} \frac{x^2 - 2x + 1}{x^3 + 5x + 4} = \lim_{x \rightarrow \infty} \frac{\frac{x^2 - 2x + 1}{x^3}}{\frac{x^3 + 5x + 4}{x^3}} = \lim_{x \rightarrow \infty} \frac{\frac{1}{x} - \frac{2}{x^2} + \frac{1}{x^3}}{1 + \frac{5}{x^2} + \frac{4}{x^3}} = \frac{0 - 0 + 0}{1 + 0 + 0} = \boxed{0}.$$

51.

$$\begin{aligned} \lim_{x \rightarrow \infty} \left[\frac{3x}{2x + 5} - \frac{x^2 + 1}{4x^2 + 8} \right] &= \lim_{x \rightarrow \infty} \frac{3x}{2x + 5} - \lim_{x \rightarrow \infty} \frac{x^2 + 1}{4x^2 + 8} = \lim_{x \rightarrow \infty} \frac{\frac{3x}{2x + 5}}{\frac{2x + 5}{2x}} - \lim_{x \rightarrow \infty} \frac{\frac{x^2 + 1}{4x^2 + 8}}{\frac{4x^2 + 8}{4x^2}} \\ &= \lim_{x \rightarrow \infty} \frac{\frac{3}{2}}{1 + \frac{5}{2x}} - \lim_{x \rightarrow \infty} \frac{\frac{1}{4} + \frac{1}{4x^2}}{1 + \frac{2}{x^2}} = \frac{\frac{3}{2}}{1 + 0} - \frac{\frac{1}{4} + 0}{1 + 0} = \frac{3}{2} - \frac{1}{4} = \boxed{\frac{5}{4}}. \end{aligned}$$

52.

$$\begin{aligned}
\lim_{x \rightarrow \infty} \left[\frac{1}{x^2 + x + 4} - \frac{x+1}{3x-1} \right] &= \lim_{x \rightarrow \infty} \frac{1}{x^2 + x + 4} - \lim_{x \rightarrow \infty} \frac{x+1}{3x-1} = \lim_{x \rightarrow \infty} \frac{\frac{1}{x^2}}{\frac{x^2 + x + 4}{x^2}} - \lim_{x \rightarrow \infty} \frac{\frac{x+1}{3x}}{\frac{3x-1}{3x}} \\
&= \lim_{x \rightarrow \infty} \frac{\frac{1}{x^2}}{1 + \frac{1}{x} + \frac{4}{x^2}} - \lim_{x \rightarrow \infty} \frac{\frac{1}{3} + \frac{1}{3x}}{1 - \frac{1}{3x}} \\
&= \frac{0}{1+0+0} - \frac{\frac{1}{3}+0}{1-0} = 0 - \frac{1}{3} = \boxed{-\frac{1}{3}}.
\end{aligned}$$

53.

$$\begin{aligned}
\lim_{x \rightarrow -\infty} \left[2e^x \left(\frac{5x+1}{3x} \right) \right] &= \lim_{x \rightarrow -\infty} (2e^x) \cdot \lim_{x \rightarrow -\infty} \frac{5x+1}{3x} = \lim_{x \rightarrow -\infty} (2e^x) \cdot \left(\lim_{x \rightarrow -\infty} \frac{\frac{5x+1}{3x}}{\frac{3x}{3x}} \right) \\
&= \lim_{x \rightarrow -\infty} (2e^x) \cdot \lim_{x \rightarrow -\infty} \frac{\frac{5}{3} + \frac{1}{3x}}{1} = 0 \cdot \frac{\frac{5}{3}+0}{1} = \boxed{0}.
\end{aligned}$$

54.

$$\begin{aligned}
\lim_{x \rightarrow -\infty} \left[e^x \left(\frac{x^2 + x - 3}{2x^3 - x^2} \right) \right] &= \lim_{x \rightarrow -\infty} e^x \cdot \lim_{x \rightarrow -\infty} \frac{x^2 + x - 3}{2x^3 - x^2} = \lim_{x \rightarrow -\infty} e^x \cdot \left(\lim_{x \rightarrow -\infty} \frac{\frac{x^2 + x - 3}{2x^3}}{\frac{2x^3 - x^2}{2x^3}} \right) \\
&= \lim_{x \rightarrow -\infty} e^x \cdot \lim_{x \rightarrow -\infty} \frac{\frac{1}{2x} + \frac{1}{2x^2} - \frac{3}{2x^3}}{1 - \frac{1}{2x}} = 0 \cdot \frac{0+0-0}{1-0} = \boxed{0}.
\end{aligned}$$

$$55. \lim_{x \rightarrow \infty} \frac{\sqrt{x} + 2}{3x - 4} = \lim_{x \rightarrow \infty} \frac{\frac{\sqrt{x} + 2}{3x}}{\frac{3x - 4}{3x}} = \lim_{x \rightarrow \infty} \frac{\frac{1}{3\sqrt{x}} + \frac{2}{3x}}{1 - \frac{4}{3x}} = \frac{0+0}{1-0} = \boxed{0}.$$

$$56. \lim_{x \rightarrow \infty} \frac{\sqrt{3x^3} + 2}{x^2 + 6} = \lim_{x \rightarrow \infty} \frac{\frac{\sqrt{3x^3} + 2}{x^2}}{\frac{x^2 + 6}{x^2}} = \lim_{x \rightarrow \infty} \frac{\frac{\sqrt{3}}{\sqrt{x}} + \frac{2}{x^2}}{1 + \frac{6}{x^2}} = \frac{0+0}{1+0} = \boxed{0}.$$

57. Because

$$\lim_{x \rightarrow \infty} \frac{3x^2 - 1}{x^2 + 4} = \lim_{x \rightarrow \infty} \frac{\frac{3x^2 - 1}{x^2}}{\frac{x^2 + 4}{x^2}} = \lim_{x \rightarrow \infty} \frac{3 - \frac{1}{x^2}}{1 + \frac{4}{x^2}} = \frac{3-0}{1+0} = 3,$$

it follows that

$$\lim_{x \rightarrow \infty} \sqrt{\frac{3x^2 - 1}{x^2 + 4}} = \sqrt{\lim_{x \rightarrow \infty} \frac{3x^2 - 1}{x^2 + 4}} = \boxed{\sqrt{3}}.$$

58. Because

$$\lim_{x \rightarrow \infty} \frac{16x^3 + 2x + 1}{2x^3 + 3x} = \lim_{x \rightarrow \infty} \frac{\frac{16x^3 + 2x + 1}{2x^3}}{\frac{2x^3 + 3x}{2x^3}} = \lim_{x \rightarrow \infty} \frac{8 + \frac{1}{x^2} + \frac{1}{2x^3}}{1 + \frac{3}{2x^2}} = \frac{8+0+0}{1+0} = 8,$$

it follows that

$$\lim_{x \rightarrow \infty} \left(\frac{16x^3 + 2x + 1}{2x^3 + 3x} \right)^{2/3} = \left(\lim_{x \rightarrow \infty} \frac{16x^3 + 2x + 1}{2x^3 + 3x} \right)^{2/3} = 8^{2/3} = \boxed{4}.$$

$$59. \lim_{x \rightarrow -\infty} \frac{5x^3}{x^2 + 1} = \lim_{x \rightarrow -\infty} \frac{\frac{5x^3}{x^2}}{\frac{x^2 + 1}{x^2}} = \lim_{x \rightarrow -\infty} \frac{5x}{1 + \frac{1}{x^2}} = \boxed{-\infty}.$$

$$60. \lim_{x \rightarrow -\infty} \frac{x^4}{x - 2} = \lim_{x \rightarrow -\infty} \frac{\frac{x^4}{x}}{\frac{x - 2}{x}} = \lim_{x \rightarrow -\infty} \frac{x^3}{1 - \frac{2}{x}} = \boxed{-\infty}.$$

61. The domain of $f(x) = 3 + \frac{1}{x}$ is the set $\{x|x \neq 0\}$. The one-sided limits as x approaches 0 are

$$\lim_{x \rightarrow 0^-} \left(3 + \frac{1}{x} \right) = -\infty \quad \text{and} \quad \lim_{x \rightarrow 0^+} \left(3 + \frac{1}{x} \right) = \infty,$$

so $\boxed{x = 0 \text{ is a vertical asymptote of the graph of } f}$. Because

$$\lim_{x \rightarrow -\infty} \left(3 + \frac{1}{x} \right) = 3 + 0 = 3 \quad \text{and} \quad \lim_{x \rightarrow \infty} \left(3 + \frac{1}{x} \right) = 3 + 0 = 3,$$

$\boxed{y = 3 \text{ is a horizontal asymptote of the graph of } f}$.

62. The domain of $f(x) = 2 - \frac{1}{x^2}$ is the set $\{x|x \neq 0\}$. The one-sided limits as x approaches 0 are

$$\lim_{x \rightarrow 0^-} \left(2 - \frac{1}{x^2} \right) = -\infty \quad \text{and} \quad \lim_{x \rightarrow 0^+} \left(2 - \frac{1}{x^2} \right) = -\infty,$$

so $\boxed{x = 0 \text{ is a vertical asymptote of the graph of } f}$. Because

$$\lim_{x \rightarrow -\infty} \left(2 - \frac{1}{x^2} \right) = 2 - 0 = 2 \quad \text{and} \quad \lim_{x \rightarrow \infty} \left(2 - \frac{1}{x^2} \right) = 2 - 0 = 2,$$

$\boxed{y = 2 \text{ is a horizontal asymptote of the graph of } f}$.

63. The domain of the function $f(x) = \frac{x^2}{x^2 - 1}$ is the set $\{x|x \neq \pm 1\}$. The one-sided limits as x approaches -1 are

$$\lim_{x \rightarrow -1^-} \frac{x^2}{x^2 - 1} = \infty \quad \text{and} \quad \lim_{x \rightarrow -1^+} \frac{x^2}{x^2 - 1} = -\infty,$$

so $\boxed{x = -1 \text{ is a vertical asymptote of the graph of } f}$. The one-sided limits as x approaches 1 are

$$\lim_{x \rightarrow 1^-} \frac{x^2}{x^2 - 1} = -\infty \quad \text{and} \quad \lim_{x \rightarrow 1^+} \frac{x^2}{x^2 - 1} = \infty,$$

so $\boxed{x = 1 \text{ is also a vertical asymptote of the graph of } f}$. Because

$$\lim_{x \rightarrow -\infty} \frac{x^2}{x^2 - 1} = \lim_{x \rightarrow -\infty} \frac{\frac{x^2}{x^2}}{\frac{x^2 - 1}{x^2}} = \lim_{x \rightarrow -\infty} \frac{1}{1 - \frac{1}{x^2}} = \frac{1}{1 - 0} = 1,$$

and

$$\lim_{x \rightarrow \infty} \frac{x^2}{x^2 - 1} = \lim_{x \rightarrow \infty} \frac{\frac{x^2}{x^2}}{\frac{x^2 - 1}{x^2}} = \lim_{x \rightarrow \infty} \frac{1}{1 - \frac{1}{x^2}} = \frac{1}{1 - 0} = 1,$$

$y = 1$ is a horizontal asymptote of the graph of f .

64. The domain of the function $f(x) = \frac{2x^2 - 1}{x^2 - 1}$ is the set $\{x | x \neq \pm 1\}$. The one-sided limits as x approaches -1 are

$$\lim_{x \rightarrow -1^-} \frac{2x^2 - 1}{x^2 - 1} = \infty \quad \text{and} \quad \lim_{x \rightarrow -1^+} \frac{2x^2 - 1}{x^2 - 1} = -\infty,$$

so $x = -1$ is a vertical asymptote of the graph of f . The one-sided limits as x approaches 1 are

$$\lim_{x \rightarrow 1^-} \frac{2x^2 - 1}{x^2 - 1} = -\infty \quad \text{and} \quad \lim_{x \rightarrow 1^+} \frac{2x^2 - 1}{x^2 - 1} = \infty,$$

so $x = 1$ is also a vertical asymptote of the graph of f . Because

$$\lim_{x \rightarrow -\infty} \frac{2x^2 - 1}{x^2 - 1} = \lim_{x \rightarrow -\infty} \frac{\frac{2x^2 - 1}{x^2}}{\frac{x^2 - 1}{x^2}} = \lim_{x \rightarrow -\infty} \frac{2 - \frac{1}{x^2}}{1 - \frac{1}{x^2}} = \frac{2 - 0}{1 - 0} = 2,$$

and

$$\lim_{x \rightarrow \infty} \frac{2x^2 - 1}{x^2 - 1} = \lim_{x \rightarrow \infty} \frac{\frac{2x^2 - 1}{x^2}}{\frac{x^2 - 1}{x^2}} = \lim_{x \rightarrow \infty} \frac{2 - \frac{1}{x^2}}{1 - \frac{1}{x^2}} = \frac{2 - 0}{1 - 0} = 2,$$

$y = 2$ is a horizontal asymptote of the graph of f .

65. By completing the square, we find

$$2x^2 - x + 10 = 2 \left(x^2 - \frac{1}{2}x + \frac{1}{16} \right) + 10 - \frac{1}{8} = 2 \left(x - \frac{1}{4} \right)^2 + \frac{79}{8} \geq \frac{79}{8} > 0$$

for all x . Therefore, $\sqrt{2x^2 - x + 10}$ is defined for all x , and the domain of $f(x) = \frac{\sqrt{2x^2 - x + 10}}{2x - 3}$ is the set $\{x | x \neq \frac{3}{2}\}$. The one-sided limits as x approaches $\frac{3}{2}$ are

$$\lim_{x \rightarrow 3/2^-} \frac{\sqrt{2x^2 - x + 10}}{2x - 3} = -\infty \quad \text{and} \quad \lim_{x \rightarrow 3/2^+} \frac{\sqrt{2x^2 - x + 10}}{2x - 3} = \infty,$$

so $x = \frac{3}{2}$ is a vertical asymptote of the graph of f . To examine the limits at infinity, note that

$$\frac{\sqrt{2x^2 - x + 10}}{2x - 3} = \frac{|x| \sqrt{2 - \frac{1}{x} + \frac{10}{x^2}}}{2x - 3} = \frac{|x|}{x} \cdot \frac{\sqrt{2 - \frac{1}{x} + \frac{10}{x^2}}}{2 - \frac{3}{x}}.$$

Note that $|x|/x$ is -1 as x approaches $-\infty$ and $+1$ as x approaches ∞ ; therefore,

$$\lim_{x \rightarrow -\infty} R(x) = -\frac{\sqrt{2 - 0 + 0}}{2 - 0} = -\frac{\sqrt{2}}{2} \quad \text{and} \quad \lim_{x \rightarrow \infty} R(x) = \frac{\sqrt{2 - 0 + 0}}{2 - 0} = \frac{\sqrt{2}}{2},$$

so that $y = -\frac{\sqrt{2}}{2}$ and $y = \frac{\sqrt{2}}{2}$ are horizontal asymptotes of the graph of f .

66. The domain of the function $f(x) = \frac{\sqrt[3]{x^2 + 5x}}{x - 6}$ is the set $\{x | x \neq 6\}$. The one-sided limits as x approaches 6 are

$$\lim_{x \rightarrow 6^-} \frac{\sqrt[3]{x^2 + 5x}}{x - 6} = -\infty \quad \text{and} \quad \lim_{x \rightarrow 6^+} \frac{\sqrt[3]{x^2 + 5x}}{x - 6} = \infty,$$

so $x = 6$ is a vertical asymptote of the graph of f . Because

$$\lim_{x \rightarrow -\infty} \frac{\sqrt[3]{x^2 + 5x}}{x - 6} = \lim_{x \rightarrow -\infty} \frac{\frac{\sqrt[3]{x^2 + 5x}}{x}}{\frac{x - 6}{x}} = \lim_{x \rightarrow -\infty} \frac{\sqrt[3]{\frac{1}{x} + \frac{5}{x^2}}}{1 - \frac{6}{x}} = \frac{\sqrt[3]{0 + 0}}{1 - 0} = 0,$$

and

$$\lim_{x \rightarrow \infty} \frac{\sqrt[3]{x^2 + 5x}}{x - 6} = \lim_{x \rightarrow \infty} \frac{\frac{\sqrt[3]{x^2 + 5x}}{x}}{\frac{x - 6}{x}} = \lim_{x \rightarrow \infty} \frac{\sqrt[3]{\frac{1}{x} + \frac{5}{x^2}}}{1 - \frac{6}{x}} = \frac{\sqrt[3]{0 + 0}}{1 - 0} = 0,$$

$y = 0$ is a horizontal asymptote of the graph of f .

67. (a) Factoring the denominator of R yields

$$2x^3 + 4x^2 = 2x^2(x + 2),$$

so the domain of R is the set $\{x | x \neq -2, x \neq 0\}$.

- (b) Because

$$\lim_{x \rightarrow -\infty} \frac{-2x^2 + 1}{2x^3 + 4x^2} = \lim_{x \rightarrow -\infty} \frac{\frac{-2x^2 + 1}{2x^3}}{\frac{2x^3 + 4x^2}{2x^3}} = \lim_{x \rightarrow -\infty} \frac{-\frac{1}{x} + \frac{1}{2x^3}}{1 + \frac{2}{x}} = \frac{0 + 0}{1 + 0} = 0$$

and

$$\lim_{x \rightarrow \infty} \frac{-2x^2 + 1}{2x^3 + 4x^2} = \lim_{x \rightarrow \infty} \frac{\frac{-2x^2 + 1}{2x^3}}{\frac{2x^3 + 4x^2}{2x^3}} = \lim_{x \rightarrow \infty} \frac{-\frac{1}{x} + \frac{1}{2x^3}}{1 + \frac{2}{x}} = \frac{0 + 0}{1 + 0} = 0,$$

$y = 0$ is a horizontal asymptote of the graph of R .

- (c) The one-sided limits as x approaches -2 are

$$\lim_{x \rightarrow -2^-} \frac{-2x^2 + 1}{2x^3 + 4x^2} = \infty \quad \text{and} \quad \lim_{x \rightarrow -2^+} \frac{-2x^2 + 1}{2x^3 + 4x^2} = -\infty,$$

so $x = -2$ is a vertical asymptote of the graph of R . The one-sided limits as x approaches 0 are

$$\lim_{x \rightarrow 0^-} \frac{-2x^2 + 1}{2x^3 + 4x^2} = \infty \quad \text{and} \quad \lim_{x \rightarrow 0^+} \frac{-2x^2 + 1}{2x^3 + 4x^2} = \infty,$$

so $x = 0$ is also a vertical asymptote of the graph of R .

- (d) The only numbers where R is not defined are $x = -2$ and $x = 0$. Using the limits from part (c), it follows that as x approaches -2 from the left, the graph of R becomes unbounded in the positive direction, while as x approaches -2 from the right, the graph of R becomes unbounded in the negative direction. As x approaches 0 from either direction, the graph of R becomes unbounded in the positive direction.

68. (a) Factoring the denominator of R yields

$$x^4 - 1 = (x^2 - 1)(x^2 + 1) = (x - 1)(x + 1)(x^2 + 1),$$

so the domain of R is the set $\{x | x \neq \pm 1\}$.

- (b) Because

$$\lim_{x \rightarrow -\infty} \frac{x^3}{x^4 - 1} = \lim_{x \rightarrow -\infty} \frac{\frac{x^3}{x^4}}{\frac{x^4 - 1}{x^4}} = \lim_{x \rightarrow -\infty} \frac{\frac{1}{x}}{1 - \frac{1}{x^4}} = \frac{0}{1 - 0} = 0$$

and

$$\lim_{x \rightarrow \infty} \frac{x^3}{x^4 - 1} = \lim_{x \rightarrow \infty} \frac{\frac{x^3}{x^4}}{\frac{x^4 - 1}{x^4}} = \lim_{x \rightarrow \infty} \frac{\frac{1}{x}}{1 - \frac{1}{x^4}} = \frac{0}{1 - 0} = 0,$$

$y = 0$ is a horizontal asymptote of the graph of R .

- (c) The one-sided limits as x approaches -1 are

$$\lim_{x \rightarrow -1^-} \frac{x^3}{x^4 - 1} = -\infty \quad \text{and} \quad \lim_{x \rightarrow -1^+} \frac{x^3}{x^4 - 1} = \infty,$$

so $x = -1$ is a vertical asymptote of the graph of R . The one-sided limits as x approaches 1 are

$$\lim_{x \rightarrow 1^-} \frac{x^3}{x^4 - 1} = -\infty \quad \text{and} \quad \lim_{x \rightarrow 1^+} \frac{x^3}{x^4 - 1} = \infty,$$

so $x = 1$ is also a vertical asymptote of the graph of R .

- (d) The only numbers where R is not defined are $x = \pm 1$. Using the limits from part (c), it follows that as x approaches -1 from the left, the graph of R becomes unbounded in the negative direction, while as x approaches -1 from the right, the graph of R becomes unbounded in the positive direction. As x approaches 1 from the left, the graph of R becomes unbounded in the negative direction, while as x approaches 1 from the right, the graph of R becomes unbounded in the positive direction.

69. (a) Factoring the denominator of R yields

$$2x^2 - 7x + 6 = (2x - 3)(x - 2),$$

so the domain of R is the set $\{x | x \neq \frac{3}{2}, x \neq 2\}$.

- (b) Because

$$\lim_{x \rightarrow -\infty} \frac{x^2 + 3x - 10}{2x^2 - 7x + 6} = \lim_{x \rightarrow -\infty} \frac{\frac{x^2 + 3x - 10}{2x^2}}{\frac{2x^2 - 7x + 6}{2x^2}} = \lim_{x \rightarrow -\infty} \frac{\frac{1}{2} + \frac{3}{2x} - \frac{5}{x^2}}{1 - \frac{7}{2x} + \frac{3}{x^2}} = \frac{\frac{1}{2} + 0 - 0}{1 - 0 + 0} = \frac{1}{2}$$

and

$$\lim_{x \rightarrow \infty} \frac{x^2 + 3x - 10}{2x^2 - 7x + 6} = \lim_{x \rightarrow \infty} \frac{\frac{x^2 + 3x - 10}{2x^2}}{\frac{2x^2 - 7x + 6}{2x^2}} = \lim_{x \rightarrow \infty} \frac{\frac{1}{2} + \frac{3}{2x} - \frac{5}{x^2}}{1 - \frac{7}{2x} + \frac{3}{x^2}} = \frac{\frac{1}{2} + 0 - 0}{1 - 0 + 0} = \frac{1}{2},$$

$y = \frac{1}{2}$ is a horizontal asymptote of the graph of R .

- (c) The one-sided limits as x approaches $\frac{3}{2}$ are

$$\lim_{x \rightarrow 3/2^-} \frac{x^2 + 3x - 10}{2x^2 - 7x + 6} = \lim_{x \rightarrow 3/2^-} \frac{(x-2)(x+5)}{(2x-3)(x-2)} = -\infty$$

and

$$\lim_{x \rightarrow 3/2^+} \frac{x^2 + 3x - 10}{2x^2 - 7x + 6} = \lim_{x \rightarrow 3/2^+} \frac{(x-2)(x+5)}{(2x-3)(x-2)} = \infty,$$

so $x = \frac{3}{2}$ is a vertical asymptote of the graph of R . Because

$$\lim_{x \rightarrow 2} \frac{x^2 + 3x - 10}{2x^2 - 7x + 6} = \lim_{x \rightarrow 2} \frac{(x-2)(x+5)}{(2x-3)(x-2)} = \lim_{x \rightarrow 2} \frac{x+5}{2x-3} = 7,$$

$x = 2$ is not a vertical asymptote of the graph of R . Rather, the graph of R has a hole at the point $(2, 7)$.

- (d) The only numbers where R is not defined are $x = \frac{3}{2}$ and $x = 2$. Using the limits from part (c), it follows that as x approaches $\frac{3}{2}$ from the left, the graph of R becomes unbounded in the negative direction, while as x approaches $\frac{3}{2}$ from the right, the graph of R becomes unbounded in the positive direction. The graph of R has a hole at the point $(2, 7)$ and approaches that point as x approaches 2 from either direction.
70. (a) The domain of R is the set $\{x | x \neq -3\}$.
- (b) Because

$$\lim_{x \rightarrow -\infty} \frac{x(x-1)^2}{(x+3)^3} = \lim_{x \rightarrow -\infty} \frac{\frac{x(x-1)^2}{x^3}}{\frac{(x+3)^3}{x^3}} = \lim_{x \rightarrow -\infty} \frac{\left(1 - \frac{1}{x}\right)^2}{\left(1 + \frac{3}{x}\right)^3} = \frac{(1-0)^2}{(1+0)^3} = 1$$

and

$$\lim_{x \rightarrow \infty} \frac{x(x-1)^2}{(x+3)^3} = \lim_{x \rightarrow \infty} \frac{\frac{x(x-1)^2}{x^3}}{\frac{(x+3)^3}{x^3}} = \lim_{x \rightarrow \infty} \frac{\left(1 - \frac{1}{x}\right)^2}{\left(1 + \frac{3}{x}\right)^3} = \frac{(1-0)^2}{(1+0)^3} = 1,$$

$y = 1$ is a horizontal asymptote of the graph of R .

- (c) The one-sided limits as x approaches -3 are

$$\lim_{x \rightarrow -3^-} \frac{x(x-1)^2}{(x+3)^3} = \infty \quad \text{and} \quad \lim_{x \rightarrow -3^+} \frac{x(x-1)^2}{(x+3)^3} = -\infty,$$

so $x = -3$ is a vertical asymptote of the graph of R .

- (d) The only number where R is not defined is $x = -3$. Using the limits from part (c), it follows that as x approaches -3 from the left, the graph of R becomes unbounded in the positive direction, while as x approaches -3 from the right, the graph of R becomes unbounded in the negative direction.
71. (a) Factoring the denominator of R yields

$$x - x^2 = x(1 - x),$$

so the domain of R is the set $\{x | x \neq 0, x \neq 1\}$.

(b) Because

$$\lim_{x \rightarrow -\infty} \frac{x^3 - 1}{x - x^2} = \lim_{x \rightarrow -\infty} \frac{\frac{x^3 - 1}{-x^2}}{\frac{x - x^2}{-x^2}} = \lim_{x \rightarrow -\infty} \frac{-x + \frac{1}{x^2}}{-\frac{1}{x} + 1} = \infty$$

and

$$\lim_{x \rightarrow \infty} \frac{x^3 - 1}{x - x^2} = \lim_{x \rightarrow \infty} \frac{\frac{x^3 - 1}{-x^2}}{\frac{x - x^2}{-x^2}} = \lim_{x \rightarrow \infty} \frac{-x + \frac{1}{x^2}}{-\frac{1}{x} + 1} = -\infty,$$

the graph of R has no horizontal asymptotes.

(c) The one-sided limits as x approaches 0 are

$$\lim_{x \rightarrow 0^-} \frac{x^3 - 1}{x - x^2} = \lim_{x \rightarrow 0^-} \frac{(x - 1)(x^2 + x + 1)}{x(1 - x)} = \infty$$

and

$$\lim_{x \rightarrow 0^+} \frac{x^3 - 1}{x - x^2} = \lim_{x \rightarrow 0^+} \frac{(x - 1)(x^2 + x + 1)}{x(1 - x)} = -\infty,$$

so $x = 0$ is a vertical asymptote of the graph of R . As x approaches 1,

$$\begin{aligned} \lim_{x \rightarrow 1} \frac{x^3 - 1}{x - x^2} &= \lim_{x \rightarrow 1} \frac{(x - 1)(x^2 + x + 1)}{x(1 - x)} \\ &= -\lim_{x \rightarrow 1} \frac{x^2 + x + 1}{x} = -\frac{1 + 1 + 1}{1} = -3; \end{aligned}$$

therefore, $x = 1$ is not a vertical asymptote of the graph of R . Rather, the graph of R has a hole at the point $(1, -3)$.

(d) The only numbers where R is not defined are $x = 0$ and $x = 1$. Using the limits from part (c), it follows that as x approaches 0 from the left, the graph of R becomes unbounded in the positive direction, while as x approaches 0 from the right, the graph of R becomes unbounded in the negative direction. The graph of R has a hole at the point $(1, -3)$ and approaches that point as x approaches 1 from either direction.

72. (a) Factoring the denominator of R yields

$$x^3 - 1 = (x - 1)(x^2 + x + 1),$$

so the domain of R is the set $\{x | x \neq 1\}$.

(b) Because

$$\lim_{x \rightarrow -\infty} \frac{4x^5}{x^3 - 1} = \lim_{x \rightarrow -\infty} \frac{\frac{4x^5}{x^3}}{\frac{x^3 - 1}{x^3}} = \lim_{x \rightarrow -\infty} \frac{4x^2}{1 - \frac{1}{x^3}} = \infty$$

and

$$\lim_{x \rightarrow \infty} \frac{4x^5}{x^3 - 1} = \lim_{x \rightarrow \infty} \frac{\frac{4x^5}{x^3}}{\frac{x^3 - 1}{x^3}} = \lim_{x \rightarrow \infty} \frac{4x^2}{1 - \frac{1}{x^3}} = \infty,$$

the graph of R has no horizontal asymptotes.

- (c) The one-sided limits as x approaches 1 are

$$\lim_{x \rightarrow 1^-} \frac{4x^5}{x^3 - 1} = -\infty \quad \text{and} \quad \lim_{x \rightarrow 1^+} \frac{4x^5}{x^3 - 1} = \infty,$$

so $x = 1$ is a vertical asymptote of the graph of R .

- (d) The only number where R is not defined is $x = 1$. Using the limits from part (c), it follows that as x approaches 1 from the left, the graph of R becomes unbounded in the negative direction, while as x approaches 1 from the right, the graph of R becomes unbounded in the positive direction.

Applications and Extensions

73. (a) Answers will vary. The figure below displays the graph of a function f with the properties

$$f(3) = 0, \quad \lim_{x \rightarrow \infty} f(x) = 1, \quad \lim_{x \rightarrow -\infty} f(x) = 1, \quad \lim_{x \rightarrow 1^-} f(x) = \infty, \quad \text{and} \quad \lim_{x \rightarrow 1^+} f(x) = -\infty.$$

- (b) Answers will vary. The function shown above is $f(x) = \frac{x-3}{x-1}$.

74. (a) Answers will vary. The figure below displays the graph of a function f with the properties

$$f(2) = 0, \quad \lim_{x \rightarrow \infty} f(x) = 0, \quad \lim_{x \rightarrow -\infty} f(x) = 0, \quad \lim_{x \rightarrow 0} f(x) = \infty,$$

$$\lim_{x \rightarrow 5^-} f(x) = -\infty, \quad \text{and} \quad \lim_{x \rightarrow 5^+} f(x) = \infty.$$

- (b) Answers will vary. The function shown above is $f(x) = \frac{x-2}{x^2(x-5)}$.

75. (a) Because $k < 0$,

$$\lim_{t \rightarrow \infty} u(t) = \lim_{t \rightarrow \infty} [(u_0 - T)e^{kt} + T] = (u_0 - T) \lim_{t \rightarrow \infty} e^{kt} + \lim_{t \rightarrow \infty} T = (u_0 - T)(0) + T = T.$$

As time increases, one would expect the object to lose heat to its surroundings until the temperature of the object had decreased to the temperature of the surroundings, so this limit value is in line with expectations.

- (b)

$$\begin{aligned} \lim_{t \rightarrow 0^+} u(t) &= \lim_{t \rightarrow 0^+} [(u_0 - T)e^{kt} + T] = (u_0 - T) \lim_{t \rightarrow 0^+} e^{kt} + \lim_{t \rightarrow 0^+} T \\ &= (u_0 - T)e^{k(0)} + T = (u_0 - T) + T = u_0. \end{aligned}$$

This value is again in line with expectations because as t approaches 0 from the right, the temperature should approach the temperature of the object when it was placed into the lower temperature medium.

76. (a) To remove 45% of the pollutants, $p = 45$, and

$$C(45) = \frac{70,000(45)}{100 - 45} \approx 57,272.73.$$

The cost to remove 45% of the pollutants is therefore approximately \$57,272.73.

- (b) To remove 90% of the pollutants, $p = 90$, and

$$C(90) = \frac{70,000(90)}{100 - 90} = 630,000.$$

The cost to remove 90% of the pollutants is therefore \$630,000.

(c) $\lim_{p \rightarrow 100^-} C(p) = \lim_{p \rightarrow 100^-} \frac{70,000p}{100 - p} = \infty.$

- (d) As the percentage of the pollutants removed from the air increases toward 100, the cost of removing those pollutants increases without bound.

77. $\lim_{x \rightarrow 100^-} C(x) = \lim_{x \rightarrow 100^-} \frac{5x}{100 - x} = \infty.$ As the percentage of the pollutants removed from the lake increases toward 100, the cost of removing those pollutants increases without bound.

78. (a) The projected size of the colony after 1 year (365 days) is

$$P(365) = \frac{50(1 + 0.5 \cdot 365)}{2 + 0.01 \cdot 365} = \frac{9175}{5.65} \approx 1623.89,$$

or 1624 insects.

- (b) The largest population that the protected area can sustain is

$$\begin{aligned} \lim_{t \rightarrow \infty} P(t) &= \lim_{t \rightarrow \infty} \frac{50(1 + 0.5t)}{2 + 0.01t} = \lim_{t \rightarrow \infty} \frac{50(1 + 0.5t)}{2 + 0.01t} \cdot \frac{\frac{1}{t}}{\frac{1}{t}} \\ &= \lim_{t \rightarrow \infty} \frac{50\left(\frac{1}{t} + 0.5\right)}{\frac{2}{t} + 0.01} = \frac{50(0 + 0.5)}{0 + 0.01} = 2500 \text{ insects}. \end{aligned}$$

- (c) The figure below displays the graph of the population P as a function of time t .

- (d) Within the first year, the population increases rapidly from the initial size of 25 insects to over 1600 insects. After that the population grows more slowly, eventually leveling off at 2500 insects, which is consistent with the result from part (b).

79. (a) If the model is correct, the environment can sustain

$$\begin{aligned}\lim_{t \rightarrow \infty} P(t) &= \lim_{t \rightarrow \infty} \frac{500}{1 + 82.3e^{-0.162t}} = \frac{\lim_{t \rightarrow \infty} 500}{\lim_{t \rightarrow \infty} [1 + 82.3e^{-0.162t}]} \\ &= \frac{500}{1 + 82.3 \lim_{t \rightarrow \infty} e^{-0.162t}} = \frac{500}{1 + 82.3(0)} = \boxed{500 \text{ bald eagles}}.\end{aligned}$$

- (b) The figure below displays the graph of the population P as a function of time t .

- (c) The number of bald eagles increases slowly for roughly the first ten years, after which the rate of population growth accelerates rapidly. This phase of growth continues until roughly year 35, after which the rate of growth slows dramatically. Eventually, the number of bald eagles levels off at 500, which is consistent with the result from part (a).

80. (a) The limiting speed of the hailstone is

$$\lim_{t \rightarrow \infty} v(t) = \lim_{t \rightarrow \infty} \left[\frac{mg}{k} (1 - e^{-kt/m}) \right] = \frac{mg}{k} \left(1 - \lim_{t \rightarrow \infty} e^{-kt/m} \right) = \frac{mg}{k} (1 - 0) = \frac{mg}{k}.$$

With $m = 4.8 \times 10^{-4}$ kg, $g = 9.8$ m/s², and $k = 3.4 \times 10^{-4}$ kg/s, the limiting speed is

$$\frac{4.8 \times 10^{-4} \text{ kg} \cdot 9.8 \text{ m/s}^2}{3.4 \times 10^{-4} \text{ kg/s}} \approx \boxed{13.84 \text{ m/s}}.$$

In miles per hour, this is

$$13.84 \text{ m/s} \cdot \frac{1 \text{ mi/h}}{0.447 \text{ m/s}} \approx \boxed{30.96 \text{ mi/h}}.$$

- (b) The figure below displays a graph of $v(t)$. The speed appears to approach 13.84 m/s, consistent with the result from part (a).

81. (a) The figure below displays the graph of $y = x(t)$. The graph suggests that $\lim_{t \rightarrow \infty} x(t) = 0$.

- (b) Note that $-1 \leq \cos t \leq 1$ and $-1 \leq \sin t \leq 1$ for all t . Thus,

$$-1.2e^{-t/2} \leq 1.2e^{-t/2} \cos t \leq 1.2e^{-t/2}$$

and

$$-2.4e^{-t/2} \leq 2.4e^{-t/2} \sin t \leq 2.4e^{-t/2}.$$

Because $\lim_{t \rightarrow \infty} e^{-t/2} = 0$, it follows that

$$\lim_{t \rightarrow \infty} (-1.2e^{-t/2}) = \lim_{t \rightarrow \infty} (1.2e^{-t/2}) = \lim_{t \rightarrow \infty} (-2.4e^{-t/2}) = \lim_{t \rightarrow \infty} (2.4e^{-t/2}) = 0,$$

so the Squeeze Theorem guarantees

$$\lim_{t \rightarrow \infty} (1.2e^{-t/2} \cos t) = 0 \quad \text{and} \quad \lim_{t \rightarrow \infty} (2.4e^{-t/2} \sin t) = 0.$$

Therefore,

$$\lim_{t \rightarrow \infty} x(t) = \lim_{t \rightarrow \infty} (1.2e^{-t/2} \cos t) + \lim_{t \rightarrow \infty} (2.4e^{-t/2} \sin t) = 0 + 0 = \boxed{0}.$$

- (c) The answer from part (b) is supported by the graph in part (a).

82. (a) First determine the value of the rate constant k . With $C(0) = 2.5$ ppm, $C(t) = 2.5e^{kt}$. Given that the amount of free chlorine after 24 hours is 2.2 ppm, it follows that

$$2.2 = 2.5e^{24k} \quad \text{or} \quad e^{24k} = \frac{2.2}{2.5},$$

so that

$$k = \frac{1}{24} \ln \left(\frac{2.2}{2.5} \right) \approx -0.005326 \text{ hours}^{-1}.$$

Thus, after 72 hours,

$$C(72) \approx 2.5e^{-0.005326(72)} \approx 1.7,$$

so the amount of free chlorine is approximately 1.7 ppm.

- (b) The approximate time when the amount of free chlorine reaches 1.0 ppm is the solution of the equation

$$1.0 = 2.5e^{-0.005326t},$$

which is

$$t = \frac{1}{-0.005326} \ln \left(\frac{1.0}{2.5} \right) \approx 172 \text{ hours}.$$

Therefore, Ben can go roughly 172 hours (a little more than one week) before he must shock the pool again.

- (c) $\lim_{t \rightarrow \infty} C(t) = \lim_{t \rightarrow \infty} (2.5e^{-0.005326t}) = \boxed{0}$ ppm.
- (d) In the long run, all of the free chlorine in the pool will decompose.
83. (a) First determine the value of the rate constant k . With $A(0) = 0.40$ moles, $A(t) = 0.40e^{kt}$. Given that the amount of sucrose present after 30 minutes is 0.36 moles, it follows that

$$0.36 = 0.40e^{30k} \quad \text{or} \quad e^{30k} = \frac{0.36}{0.40},$$

so that

$$k = \frac{1}{30} \ln \left(\frac{0.36}{0.40} \right) \approx -0.003512 \text{ minutes}^{-1}.$$

Thus, after 2 hours (120 minutes),

$$A(120) \approx 0.40e^{-0.003512(120)} \approx 0.26,$$

so the amount of sucrose present is approximately 0.26 moles.

- (b) The approximate time when the amount of sucrose remaining will be 0.10 moles is the solution of the equation

$$0.10 = 0.40e^{-0.003512t},$$

which is

$$t = \frac{1}{-0.003512} \ln \left(\frac{0.10}{0.40} \right) \approx \boxed{395 \text{ minutes}}.$$

(c) $\lim_{t \rightarrow \infty} A(t) = \lim_{t \rightarrow \infty} (0.40e^{-0.003512t}) = \boxed{0}$ moles.

(d) In the long run, all of the sucrose will decompose into glucose and fructose.

84. (a) Solving the thin film equation for q yields

$$\frac{1}{q} = \frac{1}{f} - \frac{1}{p} = \frac{p-f}{pf} \quad \text{or} \quad q = \frac{pf}{p-f}.$$

Note that division by $p-f$ is permitted here because the problem statement indicates that $p > f$, so that $p-f$ will never be equal to zero. Thus,

$$\lim_{p \rightarrow f^+} q = \lim_{p \rightarrow f^+} \frac{pf}{p-f} = \infty.$$

Therefore, the distance q of the image from the lens is not continuous as the distance of the object approaches the focal length of the lens.

(b) A camera cannot focus on an object placed close to its focal length because the distance of the image from the lens becomes unbounded.

85. If $c \neq 0$, then

$$\lim_{x \rightarrow \infty} \frac{ax^3 + b}{cx^4 + d} = \lim_{x \rightarrow \infty} \frac{ax^3 + b}{cx^4 + d} \cdot \frac{\frac{1}{x^4}}{\frac{1}{x^4}} = \lim_{x \rightarrow \infty} \frac{\frac{a}{x} + \frac{b}{x^4}}{c + \frac{d}{x^4}} = \frac{0+0}{c+0} = 0,$$

so that $y = 0$ would be a horizontal asymptote of the graph of f . Thus, for the graph of f to have no horizontal asymptotes, c must be zero. It then follows that d cannot be zero, otherwise the denominator of f would be zero. Now, with $c = 0$ and $d \neq 0$, the function f reduces to a polynomial, and therefore does not have vertical asymptotes. Next, note that if $a = 0$, then $f(x) = \frac{b}{d}$, so that

$$\lim_{x \rightarrow \infty} f(x) = \lim_{x \rightarrow \infty} \frac{b}{d} = \frac{b}{d},$$

and $y = \frac{b}{d}$ would be a horizontal asymptote of the graph of f . Thus, a cannot be zero. Finally, for the graph of f to have no horizontal or vertical asymptotes, we must have $a \neq 0$, $c = 0$, $d \neq 0$, and b can be any real number.

86. If $c \neq 0$, then

$$\lim_{x \rightarrow \infty} \frac{ax + b}{cx + d} = \lim_{x \rightarrow \infty} \frac{ax + b}{cx + d} \cdot \frac{\frac{1}{x}}{\frac{1}{x}} = \lim_{x \rightarrow \infty} \frac{a + \frac{b}{x}}{c + \frac{d}{x}} = \frac{a+0}{c+0} = \frac{a}{c},$$

so that $y = \frac{a}{c}$ would be a horizontal asymptote of the graph of f . Thus, for the graph of f to have no horizontal asymptotes, c must be zero. It then follows that d cannot be zero, otherwise the denominator of f would be zero. Now, with $c = 0$ and $d \neq 0$, the function f reduces to a polynomial, and therefore does not have vertical asymptotes. Next, note that if $a = 0$, then $f(x) = \frac{b}{d}$, so that

$$\lim_{x \rightarrow \infty} f(x) = \lim_{x \rightarrow \infty} \frac{b}{d} = \frac{b}{d},$$

and $y = \frac{b}{d}$ would be a horizontal asymptote of the graph of f . Thus, a cannot be zero. Finally, for the graph of f to have no horizontal or vertical asymptotes, we must have $a \neq 0$, $c = 0$, $d \neq 0$, and b can be any real number.

87. (a) Let n be an even positive integer. Then, as x approaches c , $(x-c)^n$ approaches 0 from the right and $\frac{1}{(x-c)^n}$ becomes unbounded in the positive direction; that is, $\lim_{x \rightarrow c} \frac{1}{(x-c)^n} = \infty$. Answers will vary, but one example is $\lim_{x \rightarrow 0} \frac{1}{x^2} = \infty$.

- (b) Let n be an odd positive integer. Then, as x approaches c from the left, $(x-c)^n$ approaches 0 from the left and $\frac{1}{(x-c)^n}$ becomes unbounded in the negative direction; that is, $\lim_{x \rightarrow c^-} \frac{1}{(x-c)^n} = -\infty$.

Answers will vary, but one example is $\lim_{x \rightarrow 4^-} \frac{1}{x-4} = -\infty$.

- (c) Let n be an odd positive integer. Then, as x approaches c from the right, $(x-c)^n$ approaches 0 from the right and $\frac{1}{(x-c)^n}$ becomes unbounded in the positive direction; that is, $\lim_{x \rightarrow c^+} \frac{1}{(x-c)^n} = \infty$.

Answers will vary, but one example is $\lim_{x \rightarrow -2^+} \frac{1}{(x+2)^3} = \infty$.

88. Let R be a rational function whose numerator and denominator have no common zeros, and let c be a point of discontinuity of R . Then c must be a zero of the denominator of R . Because the numerator and denominator of R have no common zeros, c is not a zero of the numerator, so that, as x approaches c , the numerator of R approaches a non-zero number, while the denominator approaches 0. It follows that the value of R must become unbounded as x approaches c and that the graph of R must have a vertical asymptote at $x = c$.
89. Let p be a polynomial function of degree 1 or higher. Because all polynomial functions are defined for all real numbers, the graph of p will have no vertical asymptotes. Moreover, because p contains at least one term of the form ax^k where $a \neq 0$ and k is an integer greater than or equal to 1 (as otherwise p would not be a polynomial function of degree 1 or higher), $p(x)$ will become unbounded as x becomes unbounded in either direction. Thus, the graph of f will also have no horizontal asymptotes.
90. Let P and Q be polynomial functions of degree m and n , respectively. In particular, suppose

$$P(x) = a_m x^m + a_{m-1} x^{m-1} + \cdots + a_0$$

and

$$Q(x) = b_n x^n + b_{n-1} x^{n-1} + \cdots + b_0,$$

where the a_j ($j = 0, 1, 2, \dots, m$) and the b_k ($k = 0, 1, 2, \dots, n$) are real numbers with $a_m \neq 0$ and $b_n \neq 0$.

- (a) Suppose $m > n$. Multiplying the numerator and denominator of $\frac{P(x)}{Q(x)}$ by $\frac{1}{x^n}$ then yields an expression of the form

$$\frac{a_m x^{m-n} + a_{m-1} x^{m-n-1} + \cdots + \frac{a_0}{x^n}}{b_n + \frac{b_{n-1}}{x} + \cdots + \frac{b_0}{x^n}}.$$

Thus,

$$\lim_{x \rightarrow \infty} \frac{P(x)}{Q(x)} = \begin{cases} \infty, & \text{if } a_m > 0 \\ -\infty, & \text{if } a_m < 0. \end{cases}$$

- (b) Suppose $m = n$. Multiplying the numerator and denominator of $\frac{P(x)}{Q(x)}$ by $\frac{1}{x^n}$ then yields an expression of the form

$$\frac{a_m + \frac{a_{m-1}}{x} + \cdots + \frac{a_0}{x^n}}{b_n + \frac{b_{n-1}}{x} + \cdots + \frac{b_0}{x^n}}.$$

Thus,

$$\lim_{x \rightarrow \infty} \frac{P(x)}{Q(x)} = \frac{a_m + 0 + \cdots + 0}{b_n + 0 + \cdots + 0} = \boxed{\frac{a_m}{b_n}}.$$

In other words, when $m = n$, the limit is the ratio of the leading coefficients of the two polynomial functions.

- (c) Suppose $m < n$. Multiplying the numerator and denominator of $\frac{P(x)}{Q(x)}$ by $\frac{1}{x^n}$ then yields an expression of the form

$$\frac{\frac{a_m}{x^{n-m}} + \frac{a_{m-1}}{x^{n-m+1}} + \cdots + \frac{a_0}{x^n}}{b_n + \frac{b_{n-1}}{x} + \cdots + \frac{b_0}{x^n}}.$$

Thus,

$$\lim_{x \rightarrow \infty} \frac{P(x)}{Q(x)} = \frac{0 + 0 + \cdots + 0}{b_n + 0 + \cdots + 0} = \boxed{0}.$$

91. (a) The table of values below, which have been rounded to six decimal places, suggests

$$\lim_{x \rightarrow \infty} \left(1 + \frac{1}{x}\right)^x \approx \boxed{2.718282}.$$

x	100	10,000	1,000,000	100,000,000	$\rightarrow \infty$
$f(x) = \left(1 + \frac{1}{x}\right)^x$	2.704814	2.718146	2.718280	2.718282	$f(x)$ approaches 2.718282

- (b) Using the computer algebra system *Mathematica*,

$$\lim_{x \rightarrow \infty} \left(1 + \frac{1}{x}\right)^x = \boxed{e \approx 2.718281828}.$$

- (c) Answers will vary. One possible response is that the results from parts (a) and (b) agree to five decimal places. Though it is possible to achieve accuracy to as many decimal places as desired by calculating $\left(1 + \frac{1}{x}\right)^x$ for larger and larger x , it is impossible to determine every digit of this limit. The number e , like the number π , has a nonrepeating, nonterminating decimal expansion.

Challenge Problems

92. In $\lim_{x \rightarrow \infty} \left(1 + \frac{1}{x}\right)^x$, the exponent is the variable x . The property $\lim_{x \rightarrow \infty} [f(x)]^n = \left[\lim_{x \rightarrow \infty} f(x)\right]^n$ requires the exponent to be a constant, independent of the variable x .
93. (a) As v approaches c from the left, $\frac{v^2}{c^2}$ approaches 1 and $1 - \frac{v^2}{c^2}$ approaches 0. Therefore

$$\lim_{v \rightarrow c^-} K_{\text{gen}}(v) = mc^2 \lim_{v \rightarrow c^-} \left(\frac{1}{\sqrt{1 - \frac{v^2}{c^2}}} - 1 \right) = \boxed{\infty}.$$

- (b) Because it is not possible to have infinite kinetic energy, the result from part (a) suggests that it is not possible to reach the speed of light.

1.6: The ϵ - δ Definition of a Limit

Concepts and Vocabulary

1. False. The limit of a function as x approaches c **does not depend** on the value of the function at c .
2. True. In the ϵ - δ definition of a limit, we require $0 < |x - c|$ to ensure that $x \neq c$.
3. True. In an ϵ - δ proof of a limit, the size of δ usually depends on the size of ϵ .
4. False. When proving $\lim_{x \rightarrow c} f(x) = L$ using the ϵ - δ definition, you try to find a connection between $|f(x) - L|$ and $|x - c|$.
5. True. Given any $\epsilon > 0$, suppose there is a $\delta > 0$, so that whenever $0 < |x - c| < \delta$, then $|f(x) - L| < \epsilon$. Then $\lim_{x \rightarrow c} f(x) = L$.
6. False. A function f has a limit L at infinity, if for any given $\epsilon > 0$, there is a positive number M so that whenever $x > M$, $|f(x) - L| < \epsilon$.

Skill Building

7. Here, $f(x) = 2x$, $c = 1$, and $L = 2$. To make

$$|f(x) - L| = |2x - 2| = 2|x - 1| < 0.01$$

requires

$$|x - 1| < \frac{0.01}{2} = 0.005.$$

Thus, the largest δ that “works” for $\epsilon = 0.01$ is $\delta = 0.005$.

8. Here, $f(x) = -3x$, $c = 2$, and $L = -6$. To make

$$|f(x) - L| = |-3x - (-6)| = |-3x + 6| = |-3||x - 2| = 3|x - 2| < 0.01$$

requires

$$|x - 2| < \frac{0.01}{3} = \frac{1}{300}.$$

Thus, the largest δ that “works” for $\epsilon = 0.01$ is $\delta = \frac{1}{300}$.

9. Here $f(x) = 6x - 1$, $c = 2$, and $L = 11$. To make

$$|f(x) - L| = |(6x - 1) - 11| = |6x - 12| = 6|x - 2| < \frac{1}{2}$$

requires

$$|x - 2| < \frac{1}{12}.$$

Thus, the largest δ that “works” for $\epsilon = \frac{1}{2}$ is $\delta = \frac{1}{12}$.

10. Here $f(x) = 2 - 3x$, $c = -3$, and $L = 11$. To make

$$|f(x) - L| = |(2 - 3x) - 11| = |-3x - 9| = |-3||x + 3| = 3|x + 3| < \frac{1}{3}$$

requires

$$|x + 3| < \frac{1}{9}.$$

Thus, the largest δ that “works” for $\epsilon = \frac{1}{3}$ is $\boxed{\delta = \frac{1}{9}}$.

11. Here $f(x) = -\frac{1}{2}x + 5$, $c = 2$, and $L = 4$. To make

$$|f(x) - L| = \left| \left(-\frac{1}{2}x + 5 \right) - 4 \right| = \left| -\frac{1}{2}x + 1 \right| = \left| -\frac{1}{2} \right| |x - 2| = \frac{1}{2}|x - 2| < 0.01$$

requires

$$|x - 2| < 2(0.01) = 0.02.$$

Thus, the largest δ that “works” for $\epsilon = 0.01$ is $\boxed{\delta = 0.02}$.

12. Here $f(x) = 3x + \frac{1}{2}$, $c = \frac{5}{6}$, and $L = 3$. To make

$$|f(x) - L| = \left| \left(3x + \frac{1}{2} \right) - 3 \right| = \left| 3x - \frac{5}{2} \right| = 3 \left| x - \frac{5}{6} \right| < 0.3$$

requires

$$\left| x - \frac{5}{6} \right| < \frac{0.3}{3} = 0.1.$$

Thus, the largest δ that “works” for $\epsilon = 0.3$ is $\boxed{\delta = 0.1}$.

13. To make

$$|(4x - 1) - 11| = |4x - 12| = 4|x - 3| < \epsilon$$

requires

$$|x - 3| < \frac{\epsilon}{4}.$$

Thus, the largest δ that “works” for an arbitrary ϵ is $\delta = \frac{\epsilon}{4}$.

(a) For $\epsilon = 0.1$, we can choose any $\boxed{\delta \leq \frac{0.1}{4} = 0.025}$.

(b) For $\epsilon = 0.01$, we can choose any $\boxed{\delta \leq \frac{0.01}{4} = 0.0025}$.

(c) For $\epsilon = 0.001$, we can choose any $\boxed{\delta \leq \frac{0.001}{4} = 0.00025}$.

(d) For arbitrary $\epsilon > 0$, we can choose any $\boxed{\delta \leq \frac{\epsilon}{4}}$.

14. To make

$$|(2 - 5x) - 12| = |-5x - 10| = |-5| |x + 2| = 5|x + 2| < \epsilon$$

requires

$$|x + 2| < \frac{\epsilon}{5}.$$

Thus, the largest δ that “works” for an arbitrary ϵ is $\delta = \frac{\epsilon}{5}$.

(a) For $\epsilon = 0.2$, we can choose any $\boxed{\delta \leq \frac{0.2}{5} = 0.04}$.

(b) For $\epsilon = 0.02$, we can choose any $\delta \leq \frac{0.02}{5} = 0.004$.

(c) For $\epsilon = 0.002$, we can choose any $\delta \leq \frac{0.002}{5} = 0.0004$.

(d) For arbitrary $\epsilon > 0$, we can choose any $\delta \leq \frac{\epsilon}{5}$.

15. The inequality $0 < |x + 3|$ guarantees that x cannot be equal to -3 . Now, for $x \neq -3$,

$$\frac{x^2 - 9}{x + 3} = \frac{(x + 3)(x - 3)}{x + 3} = x - 3.$$

Therefore, for $x \neq -3$,

$$\left| \frac{x^2 - 9}{x + 3} - (-6) \right| = |(x - 3) + 6| = |x + 3|.$$

To make this less than ϵ , requires $|x + 3| < \epsilon$, so the largest δ that “works” for an arbitrary ϵ is $\delta = \epsilon$.

(a) For $\epsilon = 0.1$, we can choose any $\delta \leq 0.1$.

(b) For $\epsilon = 0.01$, we can choose any $\delta \leq 0.01$.

(c) For arbitrary $\epsilon > 0$, we can choose any $\delta \leq \epsilon$.

16. The inequality $0 < |x - 2|$ guarantees that x cannot be equal to 2. Now, for $x \neq 2$,

$$\frac{x^2 - 4}{x - 2} = \frac{(x + 2)(x - 2)}{x - 2} = x + 2.$$

Therefore, for $x \neq 2$,

$$\left| \frac{x^2 - 4}{x - 2} - 4 \right| = |(x + 2) - 4| = |x - 2|.$$

To make this less than ϵ , requires $|x - 2| < \epsilon$, so the largest δ that “works” for an arbitrary ϵ is $\delta = \epsilon$.

(a) For $\epsilon = 0.1$, we can choose any $\delta \leq 0.1$.

(b) For $\epsilon = 0.01$, we can choose any $\delta \leq 0.01$.

(c) For arbitrary $\epsilon > 0$, we can choose any $\delta \leq \epsilon$.

17. Given any $\epsilon > 0$, we must find a number $\delta > 0$ so that whenever $0 < |x - c| < \delta$, then $|f(x) - L| < \epsilon$. Here $f(x) = 3x$, $c = 2$, and $L = 6$. To make

$$|f(x) - L| = |3x - 6| = 3|x - 2| < \epsilon$$

requires $|x - 2| < \epsilon/3$. Thus, the largest δ that “works” for an arbitrary ϵ is $\delta = \frac{\epsilon}{3}$. The ϵ - δ proof may be written as follows:

Given any $\epsilon > 0$, we can choose $\delta = \epsilon/3$. Whenever $0 < |x - 2| < \delta$, then

$$|f(x) - L| = |3x - 6| = 3|x - 2| < 3\delta = 3 \cdot \frac{\epsilon}{3} = \epsilon.$$

Therefore, $\lim_{x \rightarrow 2} (3x) = 6$.

18. Given any $\epsilon > 0$, we must find a number $\delta > 0$ so that whenever $0 < |x - c| < \delta$, then $|f(x) - L| < \epsilon$. Here $f(x) = 4x$, $c = 3$, and $L = 12$. To make

$$|f(x) - L| = |4x - 12| = 4|x - 3| < \epsilon$$

requires $|x - 3| < \epsilon/4$. Thus, the largest δ that “works” for an arbitrary ϵ is $\delta = \frac{\epsilon}{4}$. The ϵ - δ proof may be written as follows:

Given any $\epsilon > 0$, we can choose $\delta = \epsilon/4$. Whenever $0 < |x - 3| < \delta$, then

$$|f(x) - L| = |4x - 12| = 4|x - 3| < 4\delta = 4 \cdot \frac{\epsilon}{4} = \epsilon.$$

Therefore, $\lim_{x \rightarrow 3} (4x) = 12$.

19. Given any $\epsilon > 0$, we must find a number $\delta > 0$ so that whenever $0 < |x - c| < \delta$, then $|f(x) - L| < \epsilon$. Here $f(x) = 2x + 5$, $c = 0$, and $L = 5$. To make

$$|f(x) - L| = |(2x + 5) - 5| = 2|x| < \epsilon$$

requires $|x| = |x - 0| < \epsilon/2$. Thus, the largest δ that “works” for an arbitrary ϵ is $\delta = \frac{\epsilon}{2}$. The ϵ - δ proof may be written as follows:

Given any $\epsilon > 0$, we can choose $\delta = \epsilon/2$. Whenever $0 < |x - 0| = |x| < \delta$, then

$$|f(x) - L| = |(2x + 5) - 5| = 2|x| < 2\delta = 2 \cdot \frac{\epsilon}{2} = \epsilon.$$

Therefore, $\lim_{x \rightarrow 0} (2x + 5) = 5$.

20. Given any $\epsilon > 0$, we must find a number $\delta > 0$ so that whenever $0 < |x - c| < \delta$, then $|f(x) - L| < \epsilon$. Here $f(x) = 2 - 3x$, $c = -1$, and $L = 5$. To make

$$|f(x) - L| = |(2 - 3x) - 5| = |-3x - 3| = |-3| |x + 1| = 3|x + 1| < \epsilon$$

requires $|x + 1| < \epsilon/3$. Thus, the largest δ that “works” for an arbitrary ϵ is $\delta = \frac{\epsilon}{3}$. The ϵ - δ proof may be written as follows:

Given any $\epsilon > 0$, we can choose $\delta = \epsilon/3$. Whenever $0 < |x - (-1)| = |x + 1| < \delta$, then

$$|f(x) - L| = |(2 - 3x) - 5| = |-3x - 3| = 3|x + 1| < 3\delta = 3 \cdot \frac{\epsilon}{3} = \epsilon.$$

Therefore, $\lim_{x \rightarrow -1} (2 - 3x) = 5$.

21. Given any $\epsilon > 0$, we must find a number $\delta > 0$ so that whenever $0 < |x - c| < \delta$, then $|f(x) - L| < \epsilon$. Here $f(x) = -5x + 2$, $c = -3$, and $L = 17$. To make

$$|f(x) - L| = |(-5x + 2) - 17| = |-5x - 15| = |-5| |x + 3| = 5|x + 3| < \epsilon$$

requires $|x + 3| < \epsilon/5$. Thus, the largest δ that “works” for an arbitrary ϵ is $\delta = \frac{\epsilon}{5}$. The ϵ - δ proof may be written as follows:

Given any $\epsilon > 0$, we can choose $\delta = \epsilon/5$. Whenever $0 < |x - (-3)| = |x + 3| < \delta$, then

$$|f(x) - L| = |(-5x + 2) - 17| = |-5x - 15| = 5|x + 3| < 5\delta = 5 \cdot \frac{\epsilon}{5} = \epsilon.$$

Therefore, $\lim_{x \rightarrow -3} (-5x + 2) = 17$.

22. Given any $\epsilon > 0$, we must find a number $\delta > 0$ so that whenever $0 < |x - c| < \delta$, then $|f(x) - L| < \epsilon$. Here $f(x) = 2x - 3$, $c = 2$, and $L = 1$. To make

$$|f(x) - L| = |(2x - 3) - 1| = |2x - 4| = 2|x - 2| < \epsilon$$

requires $|x - 2| < \epsilon/2$. Thus, the largest δ that “works” for an arbitrary ϵ is $\delta = \frac{\epsilon}{2}$. The ϵ - δ proof may be written as follows:

Given any $\epsilon > 0$, we can choose $\delta = \epsilon/2$. Whenever $0 < |x - 2| < \delta$, then

$$|f(x) - L| = |(2x - 3) - 1| = 2|x - 2| < 2\delta = 2 \cdot \frac{\epsilon}{2} = \epsilon.$$

Therefore, $\lim_{x \rightarrow 2} (2x - 3) = 1$.

23. Given any $\epsilon > 0$, we must find a number $\delta > 0$ so that whenever $0 < |x - c| < \delta$, then $|f(x) - L| < \epsilon$. Here $f(x) = x^2 - 2x$, $c = 2$, and $L = 0$. Then

$$|f(x) - L| = |(x^2 - 2x) - 0| = |x(x - 2)| = |x| \cdot |x - 2|.$$

The factor $|x - 2|$ will be smaller than δ , but what about the factor $|x|$? If, in addition to any other restrictions placed on δ , we require $\delta \leq 1$, then $|x - 2| < \delta$ guarantees that $|x - 2| < 1$. Removing the absolute value from this last inequality yields $-1 < x - 2 < 1$, or $1 < x < 3$. Thus, $|x| < 3$ and

$$|f(x) - L| = |x| \cdot |x - 2| < 3|x - 2| < 3\delta.$$

To make this less than ϵ , we can choose $\delta \leq \epsilon/3$. Combining all of this information, the ϵ - δ proof may be written as follows:

Given any $\epsilon > 0$, we can choose $\delta = \min \left\{ 1, \frac{\epsilon}{3} \right\}$. Whenever $0 < |x - 2| < \delta$, it follows that $|x| < 3$, and then

$$|f(x) - L| = |(x^2 - 2x) - 0| = |x| \cdot |x - 2| < 3|x - 2| < 3\delta \leq 3 \cdot \frac{\epsilon}{3} = \epsilon.$$

Therefore, $\lim_{x \rightarrow 2} (x^2 - 2x) = 0$.

24. Given any $\epsilon > 0$, we must find a number $\delta > 0$ so that whenever $0 < |x - c| < \delta$, then $|f(x) - L| < \epsilon$. Here $f(x) = x^2 + 3x$, $c = 0$, and $L = 0$. Then

$$|f(x) - L| = |(x^2 + 3x) - 0| = |x(x + 3)| = |x| \cdot |x + 3|.$$

The factor $|x|$ will be smaller than δ , but what about the factor $|x + 3|$? If, in addition to any other restrictions placed on δ , we require $\delta \leq 1$, then $|x| < \delta$ guarantees that $|x| < 1$, or $-1 < x < 1$. Thus, $2 < x + 3 < 4$, so that $|x + 3| < 4$ and

$$|f(x) - L| = |x| \cdot |x + 3| < 4|x| < 4\delta.$$

To make this less than ϵ , we can choose $\delta \leq \epsilon/4$. Combining all of this information, the ϵ - δ proof may be written as follows:

Given any $\epsilon > 0$, we can choose $\delta = \min \left\{ 1, \frac{\epsilon}{4} \right\}$. Whenever $0 < |x| < \delta$, it follows that $|x + 3| < 4$, and then

$$|f(x) - L| = |(x^2 + 3x) - 0| = |x| \cdot |x + 3| < 4|x| < 4\delta \leq 4 \cdot \frac{\epsilon}{4} = \epsilon.$$

Therefore, $\lim_{x \rightarrow 0} (x^2 + 3x) = 0$.

25. Given any $\epsilon > 0$, we must find a number $\delta > 0$ so that whenever $0 < |x - c| < \delta$, then $|f(x) - L| < \epsilon$. Here $f(x) = \frac{1+2x}{3-x}$, $c = 1$, and $L = \frac{3}{2}$. Then

$$|f(x) - L| = \left| \frac{1+2x}{3-x} - \frac{3}{2} \right| = \left| \frac{7x-7}{2(3-x)} \right| = \frac{7}{2} \frac{|x-1|}{|3-x|}.$$

The factor $|x-1|$ will be smaller than δ , but what about the factor $|3-x|$? If, in addition to any other restrictions placed on δ , we require $\delta \leq 1$, then $|x-1| < \delta$ guarantees that $|x-1| < 1$. Removing the absolute value from this last inequality yields $-1 < x-1 < 1$, or $0 < x < 2$. Thus, $-2 < -x < 0$ and $1 < 3-x < 3$. Because $3-x > 1 > 0$, $3-x = |3-x|$, so that $1 < |3-x| < 3$. Therefore, $\frac{1}{3} < \frac{1}{|3-x|} < 1$ and

$$|f(x) - L| = \frac{7}{2} \frac{|x-1|}{|3-x|} < \frac{7}{2} |x-1| < \frac{7}{2} \delta.$$

To make this less than ϵ , we can choose $\delta \leq 2\epsilon/7$. Combining all of this information, the ϵ - δ proof may be written as follows:

Given any $\epsilon > 0$, we can choose $\delta = \min \left\{ 1, \frac{2\epsilon}{7} \right\}$. Whenever $0 < |x-1| < \delta$, it follows that $\frac{1}{|3-x|} < 1$, and then

$$|f(x) - L| = \left| \frac{1+2x}{3-x} - \frac{3}{2} \right| = \left| \frac{7x-7}{2(3-x)} \right| = \frac{7}{2} \frac{|x-1|}{|3-x|} < \frac{7}{2} |x-1| < \frac{7}{2} \delta \leq \frac{7}{2} \cdot \frac{2\epsilon}{7} = \epsilon.$$

Therefore, $\lim_{x \rightarrow 1} \frac{1+2x}{3-x} = \frac{3}{2}$.

26. Given any $\epsilon > 0$, we must find a number $\delta > 0$ so that whenever $0 < |x - c| < \delta$, then $|f(x) - L| < \epsilon$. Here $f(x) = \frac{2x}{4+x}$, $c = 2$, and $L = \frac{2}{3}$. Then

$$|f(x) - L| = \left| \frac{2x}{4+x} - \frac{2}{3} \right| = \left| \frac{4x-8}{3(4+x)} \right| = \frac{4}{3} \frac{|x-2|}{|4+x|}.$$

The factor $|x-2|$ will be smaller than δ , but what about the factor $|4+x|$? If, in addition to any other restrictions placed on δ , we require $\delta \leq 1$, then $|x-2| < \delta$ guarantees that $|x-2| < 1$. Removing the absolute value from this last inequality yields $-1 < x-2 < 1$, or $1 < x < 3$. Thus, $5 < 4+x < 7$. Because $4+x > 5 > 0$, $4+x = |4+x|$, so that $5 < |4+x| < 7$. Therefore, $\frac{1}{7} < \frac{1}{|4+x|} < \frac{1}{5}$ and

$$|f(x) - L| = \frac{4}{3} \frac{|x-2|}{|4+x|} < \frac{4}{15} |x-2| < \frac{4}{15} \delta.$$

To make this less than ϵ , we can choose $\delta \leq 15\epsilon/4$. Combining all of this information, the ϵ - δ proof may be written as follows:

Given any $\epsilon > 0$, we can choose $\delta = \min \left\{ 1, \frac{15\epsilon}{4} \right\}$. Whenever $0 < |x-2| < \delta$, it follows that $\frac{1}{|4+x|} < \frac{1}{5}$, and then

$$|f(x) - L| = \left| \frac{2x}{4+x} - \frac{2}{3} \right| = \left| \frac{4x-8}{3(4+x)} \right| = \frac{4}{3} \frac{|x-2|}{|4+x|} < \frac{4}{15} |x-2| < \frac{4}{15} \delta \leq \frac{4}{15} \cdot \frac{15\epsilon}{4} = \epsilon.$$

Therefore, $\lim_{x \rightarrow 2} \frac{2x}{4+x} = \frac{2}{3}$.

27. Given any $\epsilon > 0$, we must find a number $\delta > 0$ so that whenever $0 < |x - c| < \delta$, then $|f(x) - L| < \epsilon$. Here $f(x) = \sqrt[3]{x}$, $c = 0$, and $L = 0$. To make

$$|f(x) - L| = |\sqrt[3]{x} - 0| = \sqrt[3]{|x|} < \epsilon$$

requires $|x| = |x - 0| < \epsilon^3$. Thus, the largest δ that “works” for an arbitrary ϵ is $\delta = \epsilon^3$. The ϵ - δ proof may be written as follows:

Given any $\epsilon > 0$, we can choose $\delta = \epsilon^3$. Whenever $0 < |x - 0| = |x| < \delta$, then

$$|f(x) - L| = |\sqrt[3]{x} - 0| = \sqrt[3]{|x|} < \sqrt[3]{\delta} = \sqrt[3]{\epsilon^3} = \epsilon.$$

Therefore, $\lim_{x \rightarrow 0} \sqrt[3]{x} = 0$.

28. Given any $\epsilon > 0$, we must find a number $\delta > 0$ so that whenever $0 < |x - c| < \delta$, then $|f(x) - L| < \epsilon$. Here $f(x) = \sqrt{2 - x}$, $c = 1$, and $L = 1$. Then

$$|f(x) - L| = |\sqrt{2 - x} - 1| \cdot \frac{|\sqrt{2 - x} + 1|}{|\sqrt{2 - x} + 1|} = \frac{|(2 - x) - 1|}{|\sqrt{2 - x} + 1|} = \frac{|1 - x|}{|\sqrt{2 - x} + 1|} = \frac{|x - 1|}{|\sqrt{2 - x} + 1|}.$$

The factor $|x - 1|$ will be smaller than δ , but what about the factor $|\sqrt{2 - x} + 1|$. Because $\sqrt{2 - x} \geq 0$, $\sqrt{2 - x} + 1 \geq 1$. Thus,

$$0 < \frac{1}{\sqrt{2 - x} + 1} \leq 1 \quad \text{so that} \quad \frac{1}{|\sqrt{2 - x} + 1|} \leq 1,$$

and

$$|f(x) - L| = \frac{|x - 1|}{|\sqrt{2 - x} + 1|} \leq |x - 1|.$$

To make this less than ϵ requires $|x - 1| < \epsilon$. Therefore, the largest δ that “works” for an arbitrary ϵ is $\delta = \epsilon$. Combining all of this information, the ϵ - δ proof may be written as follows:

Given any $\epsilon > 0$, we can choose $\delta = \epsilon$. Whenever $0 < |x - 1| < \delta$, then

$$\begin{aligned} |f(x) - L| &= |\sqrt{2 - x} - 1| \cdot \frac{|\sqrt{2 - x} + 1|}{|\sqrt{2 - x} + 1|} = \frac{|(2 - x) - 1|}{|\sqrt{2 - x} + 1|} \\ &= \frac{|1 - x|}{|\sqrt{2 - x} + 1|} = \frac{|x - 1|}{|\sqrt{2 - x} + 1|} \leq |x - 1| < \delta = \epsilon. \end{aligned}$$

Therefore, $\lim_{x \rightarrow 1} \sqrt{2 - x} = 1$.

29. Given any $\epsilon > 0$, we must find a number $\delta > 0$ so that whenever $0 < |x - c| < \delta$, then $|f(x) - L| < \epsilon$. Here $f(x) = x^2$, $c = -1$, and $L = 1$. Then

$$|f(x) - L| = |x^2 - 1| = |(x - 1)(x + 1)| = |x - 1| \cdot |x + 1|.$$

The factor $|x + 1|$ will be smaller than δ , but what about the factor $|x - 1|$? If, in addition to any other restrictions placed on δ , we require $\delta \leq 1$, then $|x + 1| < \delta$ guarantees that $|x + 1| < 1$. Removing the absolute value from this last inequality yields $-1 < x + 1 < 1$, or $-2 < x < 0$. Thus, $-3 < x - 1 < -1$, so that $|x - 1| < 3$ and

$$|f(x) - L| = |x - 1| \cdot |x + 1| < 3|x + 1| < 3\delta.$$

To make this less than ϵ , we can choose $\delta \leq \epsilon/3$. Combining all of this information, the ϵ - δ proof may be written as follows:

Given any $\epsilon > 0$, we can choose $\delta = \min \left\{ 1, \frac{\epsilon}{3} \right\}$. Whenever $0 < |x + 1| < \delta$, it follows that $|x - 1| < 3$,

and then

$$|f(x) - L| = |x^2 - 1| = |x - 1| \cdot |x + 1| < 3|x + 1| < 3\delta \leq 3 \cdot \frac{\epsilon}{3} = \epsilon.$$

Therefore, $\lim_{x \rightarrow -1} x^2 = 1$.

30. Given any $\epsilon > 0$, we must find a number $\delta > 0$ so that whenever $0 < |x - c| < \delta$, then $|f(x) - L| < \epsilon$. Here $f(x) = x^3$, $c = 2$, and $L = 8$. Then

$$|f(x) - L| = |x^3 - 8| = |(x - 2)(x^2 + 2x + 4)| = |x^2 + 2x + 4| \cdot |x - 2|.$$

The factor $|x - 2|$ will be smaller than δ , but what about the factor $|x^2 + 2x + 4|$? If, in addition to any other restrictions placed on δ , we require $\delta \leq 1$, then $|x - 2| < \delta$ guarantees that $|x - 2| < 1$. Removing the absolute value from this last inequality yields $-1 < x - 2 < 1$, or $1 < x < 3$. Thus, $|x| < 3$, so that $|x^2 + 2x + 4| \leq |x|^2 + 2|x| + 4 < 19$ and

$$|f(x) - L| = |x^2 + 2x + 4| \cdot |x - 2| < 19|x - 2| < 19\delta.$$

To make this less than ϵ , we can choose $\delta \leq \epsilon/19$. Combining all of this information, the ϵ - δ proof may be written as follows:

Given any $\epsilon > 0$, we can choose $\delta = \min \left\{ 1, \frac{\epsilon}{19} \right\}$. Whenever $0 < |x - 2| < \delta$, it follows that $|x^2 + 2x + 4| < 19$, and then

$$\begin{aligned} |f(x) - L| &= |x^3 - 8| = |(x - 2)(x^2 + 2x + 4)| = |x^2 + 2x + 4| \cdot |x - 2| \\ &< 19|x - 2| < 19\delta \leq 19 \cdot \frac{\epsilon}{19} = \epsilon. \end{aligned}$$

Therefore, $\lim_{x \rightarrow 2} x^3 = 8$.

31. Given any $\epsilon > 0$, we must find a number $\delta > 0$ so that whenever $0 < |x - c| < \delta$, then $|f(x) - L| < \epsilon$. Here $f(x) = \frac{1}{x}$, $c = 3$, and $L = \frac{1}{3}$. Then

$$|f(x) - L| = \left| \frac{1}{x} - \frac{1}{3} \right| = \frac{|3 - x|}{3|x|} = \frac{|x - 3|}{3|x|}.$$

The factor $|x - 3|$ will be smaller than δ , but what about the factor $|x|$? If, in addition to any other restrictions placed on δ , we require $\delta \leq 1$, then $|x - 3| < \delta$ guarantees that $|x - 3| < 1$. Removing the absolute value from this last inequality yields $-1 < x - 3 < 1$, or $2 < x < 4$. Because $x > 2 > 0$, $x = |x|$ so that $2 < |x - 2| < 4$. Therefore, $\frac{1}{4} < \frac{1}{|x|} < \frac{1}{2}$, and

$$|f(x) - L| = \frac{|x - 3|}{3|x|} < \frac{|x - 2|}{6} < \frac{\delta}{6}.$$

To make this less than ϵ , we can choose $\delta \leq 6\epsilon$. Combining all of this information, the ϵ - δ proof may be written as follows:

Given any $\epsilon > 0$, we can choose $\delta = \min \{1, 6\epsilon\}$. Whenever $0 < |x - 3| < \delta$, it follows that $\frac{1}{|x|} < \frac{1}{2}$, and then

$$|f(x) - L| = \left| \frac{1}{x} - \frac{1}{3} \right| = \frac{|3 - x|}{3|x|} = \frac{|x - 3|}{3|x|} < \frac{|x - 2|}{6} < \frac{\delta}{6} \leq \frac{6\epsilon}{6} = \epsilon.$$

Therefore, $\lim_{x \rightarrow 3} \frac{1}{x} = \frac{1}{3}$.

32. Given any $\epsilon > 0$, we must find a number $\delta > 0$ so that whenever $0 < |x - c| < \delta$, then $|f(x) - L| < \epsilon$. Here $f(x) = \frac{1}{x^2}$, $c = 2$, and $L = \frac{1}{4}$. Then

$$|f(x) - L| = \left| \frac{1}{x^2} - \frac{1}{4} \right| = \frac{|4 - x^2|}{4x^2} = \frac{|x - 2| \cdot |x + 2|}{4x^2}.$$

The factor $|x - 2|$ will be smaller than δ , but what about the factors $|x + 2|$ and x^2 ? If, in addition to any other restrictions placed on δ , we require $\delta \leq 1$, then $|x - 2| < \delta$ guarantees that $|x - 2| < 1$.

Removing the absolute value from this last inequality yields $-1 < x - 2 < 1$, or $1 < x < 3$. Thus, $\frac{1}{x^2} < 1$ and $3 < x + 2 < 5$, so that $|x + 2| < 5$ and

$$|f(x) - L| = \frac{|x - 2| \cdot |x + 2|}{4x^2} < \frac{5}{4}|x - 2| < \frac{5}{4}\delta.$$

To make this less than ϵ , we can choose $\delta \leq 4\epsilon/5$. Combining all of this information, the ϵ - δ proof may be written as follows:

Given any $\epsilon > 0$, we can choose $\delta = \min \left\{ 1, \frac{4\epsilon}{5} \right\}$. Whenever $0 < |x - 2| < \delta$, it follows that $\frac{1}{x^2} < 1$ and $|x + 2| < 5$. Then

$$|f(x) - L| = \left| \frac{1}{x^2} - \frac{1}{4} \right| = \frac{|4 - x^2|}{4x^2} = \frac{|x - 2| \cdot |x + 2|}{4x^2} < \frac{5}{4}|x - 2| < \frac{5}{4}\delta \leq \frac{5}{4} \cdot \frac{4\epsilon}{5} = \epsilon.$$

Therefore, $\lim_{x \rightarrow 2} \frac{1}{x^2} = \frac{1}{4}$.

33. Negating the ϵ - δ definition of a limit yields the statement: $\lim_{x \rightarrow c} f(x) \neq L$ provided there is an $\epsilon > 0$ such that for any $\delta > 0$, there is an x satisfying $0 < |x - c| < \delta$ but $|f(x) - L| \geq \epsilon$. To establish that $\lim_{x \rightarrow 3} (3x - 1) \neq 12$, let $\epsilon = 1$ and $\delta > 0$. From the set of x values satisfying $0 < |x - 3| < \delta$ select any x for which $-\delta < x - 3 < 0$, or $3 - \delta < x < 3$. Then

$$-4 - 3\delta < (3x - 1) - 12 < -4 \quad \text{or} \quad |(3x - 1) - 12| > 4 > 1 = \epsilon.$$

Therefore, $\lim_{x \rightarrow 3} (3x - 1) \neq 12$.

34. Negating the ϵ - δ definition of a limit yields the statement: $\lim_{x \rightarrow c} f(x) \neq L$ provided there is an $\epsilon > 0$ such that for any $\delta > 0$, there is an x satisfying $0 < |x - c| < \delta$ but $|f(x) - L| \geq \epsilon$. To establish that $\lim_{x \rightarrow -2} (4x) \neq -7$, let $\epsilon = \frac{1}{2}$ and $\delta > 0$. From the set of x values satisfying $0 < |x + 2| < \delta$ select any x for which $-\delta < x + 2 < 0$, or $-2 - \delta < x < -2$. Then

$$-1 - 4\delta < 4x + 7 < -1 \quad \text{or} \quad |4x + 7| > 1 > \frac{1}{2} = \epsilon.$$

Therefore, $\lim_{x \rightarrow -2} (4x) \neq -7$.

Applications and Extensions

35. Note that

$$\left| \frac{1}{x^2 + 9} - \frac{1}{18} \right| = \left| \frac{18 - (x^2 + 9)}{18(x^2 + 9)} \right| = \left| \frac{9 - x^2}{18(x^2 + 9)} \right| = \frac{|3 - x| \cdot |3 + x|}{18(x^2 + 9)} = \frac{|x + 3|}{18(x^2 + 9)} |x - 3|.$$

If $2 < x < 4$, then

$$13 < x^2 + 9 < 25 \quad \text{so that} \quad \frac{1}{x^2 + 9} < \frac{1}{13}$$

and

$$5 < x + 3 < 7 \quad \text{so that} \quad |x + 3| < 7;$$

therefore,

$$\left| \frac{1}{x^2 + 9} - \frac{1}{18} \right| = \frac{|x + 3|}{18(x^2 + 9)} |x - 3| < \frac{7}{18(13)} |x - 3| = \frac{7}{234} |x - 3| < \frac{7}{234} \delta.$$

To make this less than ϵ , we can choose $\delta \leq 234\epsilon/7$. It is important to note that another restriction on δ is implicit in the analysis that has just been performed. If $2 < x < 4$, then $-1 < x - 3 < 1$, and

$|x - 3| < 1$. Thus, δ must also be less than or equal to 1. Combining all of this information, the ϵ - δ proof may be written as follows:

Given any $\epsilon > 0$, we can choose $\delta = \min \left\{ 1, \frac{234}{7}\epsilon \right\}$. Whenever $0 < |x - 3| < \delta$, it follows that

$\frac{1}{x^2 + 9} < \frac{1}{13}$ and $|x + 3| < 7$. Then

$$\left| \frac{1}{x^2 + 9} - \frac{1}{18} \right| = \frac{|x + 3|}{18(x^2 + 9)} |x - 3| < \frac{7}{234} |x - 3| < \frac{7}{234} \delta \leq \frac{7}{234} \cdot \frac{234}{7} \epsilon = \epsilon.$$

Therefore, $\lim_{x \rightarrow 3} \frac{1}{x^2 + 9} = \frac{1}{18}$.

36. Note that

$$|(2 + x)^2 - 4| = |4 + 4x + x^2 - 4| = |x(4 + x)| = |x| \cdot |x + 4|.$$

If $-1 < x < 1$, then $3 < x + 4 < 5$ and $|x + 4| < 5$. Thus,

$$|(2 + x)^2 - 4| = |x| \cdot |x + 4| < 5|x| < 5\delta.$$

To make this less than ϵ , we can choose $\delta \leq \epsilon/5$. It is important to note that another restriction on δ is implicit in the analysis that has just been performed. If $-1 < x < 1$, then $|x| < 1$. Thus, δ must also be less than or equal to 1. Combining all of this information, the ϵ - δ proof may be written as follows:

Given any $\epsilon > 0$, we can choose $\delta = \min \left\{ 1, \frac{\epsilon}{5} \right\}$. Whenever $0 < |x| < \delta$, it follows that $|x + 4| < 5$, and then

$$|(2 + x)^2 - 4| = |4 + 4x + x^2 - 4| = |x(4 + x)| = |x| \cdot |x + 4| < 5|x| < 5\delta \leq 5 \cdot \frac{\epsilon}{5} = \epsilon.$$

Therefore, $\lim_{x \rightarrow 0} (2 + x)^2 = 4$.

37. Note that

$$\left| \frac{1}{x^2 + 9} - \frac{1}{13} \right| = \left| \frac{13 - (x^2 + 9)}{13(x^2 + 9)} \right| = \left| \frac{4 - x^2}{13(x^2 + 9)} \right| = \frac{|2 - x| \cdot |2 + x|}{13(x^2 + 9)} = \frac{|x + 2|}{13(x^2 + 9)} |x - 2|.$$

If $1 < x < 3$, then

$$10 < x^2 + 9 < 18 \quad \text{so that} \quad \frac{1}{x^2 + 9} < \frac{1}{10}$$

and

$$3 < x + 2 < 5 \quad \text{so that} \quad |x + 2| < 5.$$

Thus,

$$\left| \frac{1}{x^2 + 9} - \frac{1}{13} \right| = \frac{|x + 2|}{13(x^2 + 9)} |x - 2| < \frac{5}{13(10)} |x - 2| = \frac{1}{26} |x - 2| < \frac{1}{26} \delta.$$

To make this less than ϵ , we can choose $\delta \leq 26\epsilon$. It is important to note that another restriction on δ is implicit in the analysis that has just been performed. If $1 < x < 3$, then $-1 < x - 2 < 1$ and $|x - 2| < 1$. Thus, δ must also be less than or equal to 1. Combining all of this information, the ϵ - δ proof may be written as follows:

Given any $\epsilon > 0$, we can choose $\delta = \min \{1, 26\epsilon\}$. Whenever $0 < |x - 2| < \delta$, it follows that

$\frac{1}{x^2 + 9} < \frac{1}{10}$ and $|x + 2| < 5$. Then

$$\left| \frac{1}{x^2 + 9} - \frac{1}{13} \right| = \frac{|x + 2|}{13(x^2 + 9)} |x - 2| < \frac{1}{26} |x - 2| < \frac{1}{26} \delta \leq \frac{1}{26} \cdot 26\epsilon = \epsilon.$$

Therefore, $\lim_{x \rightarrow 2} \frac{1}{x^2 + 9} = \frac{1}{13}$.

38. Negating the ϵ - δ definition of a limit yields the statement: $\lim_{x \rightarrow c} f(x) \neq L$ provided there is an $\epsilon > 0$ such that for any $\delta > 0$, there is an x satisfying $0 < |x - c| < \delta$ but $|f(x) - L| \geq \epsilon$. To establish that $\lim_{x \rightarrow 1} x^2 \neq 1.31$, let $\epsilon = 0.1$ and $\delta > 0$. If $\delta < 1$, from the set of x values satisfying $0 < |x - 1| < \delta$ select any x for which $-\delta < x - 1 < 0$, or $1 - \delta < x < 1$, and note that $1 - \delta > 0$. On the other hand, if $\delta \geq 1$, then from the set of x values satisfying $0 < |x - 1| < \delta$ select any x for which $-1 < x - 1 < 0$, or $0 < x < 1$. Then, for any $\delta > 0$,

$$x^2 < 1 \quad \text{so that} \quad |x^2 - 1.31| > 0.31 > 0.1 = \epsilon.$$

Therefore, $\lim_{x \rightarrow 1} x^2 \neq 1.31$.

39. $\text{Given any } \epsilon > 0, \text{ we can choose } \delta = \frac{\epsilon}{1 + |m|}$. The absolute value of m appears in the formula for δ to insure that δ will be positive. Moreover, 1 has been added to the denominator to allow for the possibility that m could be zero. Whenever $0 < |x - c| < \delta$, then

$$|(mx + b) - (mc + b)| = |m| |x - c| < |m| \cdot \delta = \frac{|m|}{1 + |m|} \epsilon < \epsilon.$$

Therefore, $\lim_{x \rightarrow c} (mx + b) = mc + b$.

40. Recall that

$$|x^2 - 4| = |(x - 2)(x + 2)| = |x - 2| \cdot |x + 2|.$$

If $|x - 2| < \frac{1}{3}$, then $\frac{5}{3} < x < \frac{7}{3}$, so that

$$\frac{11}{3} < x + 2 < \frac{13}{3} \quad \text{and} \quad |x + 2| < \frac{13}{3}.$$

Thus,

$$|x^2 - 4| = |x - 2| \cdot |x + 2| < \frac{13}{3} |x - 2| < \frac{13}{3} \delta.$$

To make this less than ϵ , we can choose $\delta \leq \frac{3\epsilon}{13}$. Combining the two restrictions placed on δ yields $\delta \leq \min \left\{ \frac{1}{3}, \frac{3\epsilon}{13} \right\}$.

41. For $x \neq 3$, to guarantee that $|(2x - 1) - 5| < 0.1$ requires

$$|2x - 6| = 2|x - 3| < 0.1 \quad \text{or} \quad |x - 3| < 0.05.$$

Thus, x must be within 0.05 of 3 to guarantee that $2x - 1$ differs from 5 by less than 0.1.

42. For $x \neq 0$, to guarantee that $|3^x - 1| < 0.1$ requires

$$-0.1 < 3^x - 1 < 0.1 \quad \text{or} \quad 0.9 < 3^x < 1.1.$$

This last compound inequality yields

$$-0.0959 \approx \frac{\ln 0.9}{\ln 3} < x < \frac{\ln 1.1}{\ln 3} \approx 0.0868.$$

Thus, x must be within approximately 0.087 of 0 to guarantee that 3^x differs from 1 by less than 0.1.

43. Suppose $\lim_{x \rightarrow c} f(x) = L$ where $L < 0$, and let $\epsilon = \frac{|L|}{2} > 0$. Then there is a $\delta > 0$ such that, whenever $0 < |x - c| < \delta$,

$$|f(x) - L| < \frac{|L|}{2} \quad \text{or} \quad -\frac{|L|}{2} < f(x) - L < \frac{|L|}{2}.$$

Because $L < 0$, $|L| = -L$, so the last compound inequality becomes

$$\frac{L}{2} < f(x) - L < -\frac{L}{2} \quad \text{or} \quad \frac{3L}{2} < f(x) < \frac{L}{2} < 0.$$

Thus, everywhere in the open interval $|x - c| < \delta$, except possibly at c , $f(x) < 0$.

44. Given any $\epsilon > 0$, we can choose $N = -\frac{1}{\epsilon}$. Whenever $x < N$, then

$$\left| \frac{1}{x} - 0 \right| = -\frac{1}{x} < -\frac{1}{N} = \epsilon.$$

Therefore, $\lim_{x \rightarrow -\infty} \frac{1}{x} = 0$.

45. Given any $\epsilon > 0$, we can choose $M = \frac{1}{\epsilon^2}$. Whenever $x > M$, then

$$\left| -\frac{1}{\sqrt{x}} - 0 \right| = \frac{1}{\sqrt{x}} < \frac{1}{\sqrt{M}} = \epsilon.$$

Therefore, $\lim_{x \rightarrow \infty} \left(-\frac{1}{\sqrt{x}} \right) = 0$.

46. To make

$$\left| \frac{1}{x^2} - 0 \right| = \frac{1}{x^2} < 0.1$$

requires

$$x^2 > 10 \quad \text{or} \quad |x| > \sqrt{10}.$$

As this limit is for x approaching $-\infty$, take $N = -\sqrt{10}$.

47. First, consider $L > 0$. Take $\epsilon = L/2$, let $\delta > 0$, and choose $x = -\delta/2$. Then $0 < |x - 0| = |x| < \delta$ but

$$\left| \frac{1}{x} - L \right| = \left| -\frac{2}{\delta} - L \right| = \left| \frac{2}{\delta} + L \right| > L > \frac{L}{2} = \epsilon,$$

where the inequality $L > L/2$ follows because $L > 0$. Therefore, $\lim_{x \rightarrow 0} \frac{1}{x}$ cannot equal L . Next, consider $L < 0$. Take $\epsilon = -L/2$, let $\delta > 0$, and choose $x = \delta/2$. Then $0 < |x - 0| = |x| < \delta$ but

$$\left| \frac{1}{x} - L \right| = \left| \frac{2}{\delta} + (-L) \right| > -L > -\frac{L}{2} = \epsilon,$$

where the inequality $-L > -L/2$ follows because $-L > 0$. Therefore, $\lim_{x \rightarrow 0} \frac{1}{x}$ cannot equal L . Finally, consider $L = 0$. Take $\epsilon = 1$, let $\delta > 0$, and choose $|x| < \min\{1, \delta\}$. Then $0 < |x - 0| = |x| < \delta$ but

$$\left| \frac{1}{x} - L \right| = \left| \frac{1}{x} \right| > 1 = \epsilon.$$

Therefore, $\lim_{x \rightarrow 0} \frac{1}{x}$ cannot equal 0. In summary, there is no number L such that $\lim_{x \rightarrow 0} \frac{1}{x} = L$.

48. The strict inequality on the left ($0 < |x - c|$) is to remove the function value at $x = c$ from consideration; the strict inequality on the right ($|x - c| < \delta$) is to create an **open** interval containing $x = c$.
49. A limit is supposed to capture the behavior of the value of a function as the value of the independent variable approaches a target value. We do not want the limit to depend on the value of the function at that location or even to depend on whether the function is defined at that location. Including the phrase *except possibly at c* imposes these restrictions.
50. In the ϵ - δ definition of a limit, ϵ measures the “closeness” of the function value $f(x)$ to the value of the limit L , while δ measures the “closeness” of the value of the independent variable x to the target value c . For example, notice the placement of ϵ and δ in the proof that $\lim_{x \rightarrow 3} (2x - 1) = 5$:

Given any $\epsilon > 0$, take $\delta = \epsilon/2$. Then, whenever $0 < |x - 3| < \delta$,

$$|(2x - 1) - 5| = |2x - 6| = 2|x - 3| < 2 \cdot \delta = 2 \cdot \frac{\epsilon}{2} = \epsilon.$$

Therefore, $\lim_{x \rightarrow 3} (2x - 1) = 5$.

51. First consider $\lim_{x \rightarrow 0} f(x)$. Any open interval containing 0 will contain both rational numbers and irrational numbers. As the rational numbers approach 0, the function value x^2 will approach 0; as the irrational numbers approach 0, the function value will also approach 0. This suggests that $\lim_{x \rightarrow 0} f(x) = 0$.

This argument can be made precise using $\delta = \sqrt{\epsilon}$ within the ϵ - δ definition.

Next, consider $\lim_{x \rightarrow 1} f(x)$. Any open interval containing 1 will contain both rational numbers and irrational numbers. As the rational numbers approach 1, the function value x^2 will approach 1; as the irrational numbers approach 1, however, the function value will approach 0. This suggests that $\lim_{x \rightarrow 1} f(x)$ does not exist. This argument can be made precise as follows: Suppose the limit does exist and is equal to L . Take $\epsilon = 1/4$. There would then be a δ such that whenever $0 < |x - 1| < \delta$, the function value would be within $1/4$ of L . Considering the rational and irrational values of x separately would require that L be simultaneously within $1/4$ of 1 and 0, which is impossible.

52. Any open interval containing 0 will contain both rational numbers and irrational numbers. As the rational numbers approach 0, the function value x^2 will approach 0; as the irrational numbers approach 0, the function value $\tan x$ will also approach 0. This suggests that $\lim_{x \rightarrow 0} f(x) = 0$.

Challenge Problems

53. Note that

$$|f(x) - L| = |4x^3 + 3x^2 - 24x + 22 - 5| = |4x^3 + 3x^2 - 24x + 17| = |4x^2 + 7x - 17| \cdot |x - 1|.$$

The factor $|x - 1|$ will be smaller than δ , but what about the factor $|4x^2 + 7x - 17|$? If, in addition to any other restrictions placed on δ , we require $\delta \leq 1$, then $|x - 1| < \delta$ guarantees that $|x - 1| < 1$, or $0 < x < 2$. Thus, $|x| < 2$ so that $|4x^2 + 7x - 17| \leq 4|x|^2 + 7|x| + 17 < 47$ and

$$|f(x) - L| = |4x^2 + 7x - 17| \cdot |x - 1| < 47|x - 1| < 47\delta.$$

To make this less than ϵ , we can choose $\delta \leq \epsilon/47$. Combining all of this information, the ϵ - δ proof may be written as follows:

Given any $\epsilon > 0$, we can choose $\delta = \min \left\{ 1, \frac{\epsilon}{47} \right\}$. Whenever $0 < |x - 1| < \delta$, it follows that $|4x^2 + 7x - 17| < 47$, and then

$$\begin{aligned} |f(x) - L| &= |4x^3 + 3x^2 - 24x + 22 - 5| = |4x^3 + 3x^2 - 24x + 17| = |4x^2 + 7x - 17| \cdot |x - 1| \\ &< 47|x - 1| < 47\delta \leq 47 \cdot \frac{\epsilon}{47} = \epsilon. \end{aligned}$$

Therefore, $\lim_{x \rightarrow 1} (4x^3 + 3x^2 - 24x + 22) = 5$.

54. Suppose $\lim_{x \rightarrow c} f(x) = L$ and $\lim_{x \rightarrow c} g(x) = M$. Given any $\epsilon > 0$, there then exists a $\delta_1 > 0$ such that

$$|f(x) - L| < \frac{\epsilon}{2} \quad \text{whenever} \quad 0 < |x - c| < \delta_1,$$

and a $\delta_2 > 0$ such that

$$|g(x) - M| < \frac{\epsilon}{2} \quad \text{whenever} \quad 0 < |x - c| < \delta_2.$$

Choose $\delta = \min\{\delta_1, \delta_2\}$. Whenever $0 < |x - c| < \delta$, then

$$\begin{aligned} |(f(x) + g(x)) - (L + M)| &= |(f(x) - L) + (g(x) - M)| \\ &\leq |f(x) - L| + |g(x) - M| < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon. \end{aligned}$$

Therefore, $\lim_{x \rightarrow c} [f(x) + g(x)] = L + M$.

55. First note that

$$\sqrt{5 + 4x^2} > \sqrt{4x^2} \quad \text{so that} \quad \frac{1}{\sqrt{5 + 4x^2}} < \frac{1}{\sqrt{4x^2}}$$

for all x . For $x > 2$, $2 - x < 0$ so that upon multiplying the latter inequality above by the negative expression $2 - x$,

$$\frac{2 - x}{\sqrt{5 + 4x^2}} > \frac{2 - x}{\sqrt{4x^2}} = \frac{2 - x}{2x} = \frac{1}{x} - \frac{1}{2} > -\frac{1}{2}.$$

Thus, to be within $\epsilon = 0.01$ of $L = -1/2$, we need

$$\frac{2 - x}{\sqrt{5 + 4x^2}} < -0.49 \quad \text{or} \quad \frac{x - 2}{\sqrt{5 + 4x^2}} > 0.49.$$

Squaring both sides of this last inequality and gathering terms yields

$$0.0396x^2 - 4x + 2.7995 > 0.$$

The roots of the quadratic function are

$$x = \frac{4 \pm \sqrt{16 - 4(0.0396)(2.7995)}}{2(0.0396)} \approx 100.3, 0.7.$$

so

$$\frac{2 - x}{\sqrt{5 + 4x^2}} < -0.49$$

for approximately $x < 0.7$ and $x > 100.3$. In the ϵ - δ definition of a limit at infinity, we can therefore take $\boxed{M = 101}$.

56. To prove that the linear function $f(x) = ax + b$ is continuous everywhere, it must be shown that

$\lim_{x \rightarrow c} f(x) = ac + b$ for any real number c . Now, given any $\epsilon > 0$, we can choose $\delta = \frac{\epsilon}{1 + |a|}$. The

absolute value of a appears in the formula for δ to ensure that δ will be positive. Moreover, 1 has been added to the denominator to allow for the possibility that a could be zero. Whenever $0 < |x - c| < \delta$, then

$$|(ax + b) - (ac + b)| = |a| |x - c| < |a| \cdot \delta = \frac{|a|}{1 + |a|} \epsilon < \epsilon.$$

Therefore, $\lim_{x \rightarrow c} f(x) = ac + b$, and the linear function $f(x) = ax + b$ is continuous everywhere.

57. Start by proving continuity at $x = 0$. Because 0 is a rational number, $f(0) = 0$. Now, given any $\epsilon > 0$, choose $\delta = \epsilon$. Whenever $0 < |x - c| < \delta$, then

$$|f(x) - 0| = |f(x)| = |x| < \delta = \epsilon$$

for every rational number x and

$$|f(x) - 0| = |f(x)| = 0 < \delta = \epsilon$$

for every irrational number x . Therefore, $\lim_{x \rightarrow 0} f(x) = 0 = f(0)$ and f is continuous at $x = 0$.

Now, let c be any non-zero real number. We will proceed with a proof by contradiction. Toward this end, suppose that f is continuous at $x = c$. Then the limit as x approaches c must exist and be equal to $f(c)$. Based on the definition of f , $\lim_{x \rightarrow c} f(x)$ must therefore be equal to either 0 (if c is a rational number) or c (if c is an irrational number). We will now show that neither of these are the limit. Take $\epsilon = |c|/2$, and choose $\delta > 0$. For any irrational number x such that $0 < |x - c| < \delta$,

$$|f(x) - 0| = |f(x)| = |c| > \frac{|c|}{2} = \epsilon,$$

so $\lim_{x \rightarrow c} f(x) \neq 0$. Moreover, for every rational number x such that $0 < |x - c| < \delta$,

$$|f(x) - c| = |c| > \frac{|c|}{2} = \epsilon,$$

so $\lim_{x \rightarrow c} f(x) \neq c$. Thus, $\lim_{x \rightarrow c} f(x)$ does not exist, and f is not continuous at $x = c$.

58. Let $f(x) = x^3$. Then

$$|f(x) - f(c)| = |x^3 - c^3| = |(x - c)(x^2 + cx + c^2)| = |x - c| \cdot |x^2 + cx + c^2|.$$

With both x and c in the open interval $(0, 2)$, $|x| < 2$ and $|c| < 2$. Therefore

$$|x^2 + cx + c^2| \leq |x|^2 + |c| |x| + |c|^2 < 2^2 + 2^2 + 2^2 = 12,$$

and

$$|f(x) - f(c)| = |x - c| \cdot |x^2 + cx + c^2| < 12|x - c|.$$

Thus, $\boxed{K = 12}$ is a Lipschitz constant for $f(x) = x^3$ on $(0, 2)$.

Chapter 1 Review Exercises

1. The values in the table below, which have been rounded for display purposes, suggest that the value of $f(x) = \frac{1 - \cos x}{1 + \cos x}$ can be made “as close as we please” to 0 by choosing x “sufficiently close” to 0. It therefore appears that

$$\lim_{x \rightarrow 0} \frac{1 - \cos x}{1 + \cos x} = \boxed{0}.$$

x	-0.1	-0.01	-0.001	$\rightarrow 0 \leftarrow$	0.001	0.01	0.1
$f(x) = \frac{1 - \cos x}{1 + \cos x}$	0.002504	0.000025	0.00000025	$f(x)$ approaches 0	0.00000025	0.000025	0.002504

2. The figure below displays a graph of f . Using the graph,

$$\lim_{x \rightarrow 1^-} f(x) = -3 \quad \text{and} \quad \lim_{x \rightarrow 1^+} f(x) = -3.$$

Because the two one-sided limits as x approaches 1 are equal, $\lim_{x \rightarrow 1} f(x)$ exists. Moreover, because the two one-sided limits are equal to -3 , $\boxed{\lim_{x \rightarrow 1} f(x) = -3}$.

3. The figure below displays a graph of f . Using the graph,

$$\lim_{x \rightarrow 2^-} f(x) = 6 \quad \text{and} \quad \lim_{x \rightarrow 2^+} f(x) = 5.$$

Because the two one-sided limits as x approaches 2 are not equal, $\boxed{\lim_{x \rightarrow 2} f(x) \text{ does not exist}}$.

4. Let $f(x) = x^2 - 3$.

(a) The slope of the secant line joining $(1, -2)$ and $(2, 1)$ is

$$\frac{1 - (-2)}{2 - 1} = \frac{3}{1} = \boxed{3}.$$

(b) The slope of the tangent line to the graph of f at $(1, -2)$ is

$$\begin{aligned} \lim_{h \rightarrow 0} \frac{f(1+h) - f(1)}{h} &= \lim_{h \rightarrow 0} \frac{(1+h)^2 - 3 - (-2)}{h} = \lim_{h \rightarrow 0} \frac{1 + 2h + h^2 - 3 + 2}{h} \\ &= \lim_{h \rightarrow 0} \frac{2h + h^2}{h} = \lim_{h \rightarrow 0} (2 + h) = \boxed{2}. \end{aligned}$$

5. Let $f(x) = \frac{3}{x}$. Then

$$\begin{aligned} \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} &= \lim_{h \rightarrow 0} \frac{\frac{3}{x+h} - \frac{3}{x}}{h} \cdot \frac{x(x+h)}{x(x+h)} = \lim_{h \rightarrow 0} \frac{3x - 3(x+h)}{hx(x+h)} = \lim_{h \rightarrow 0} \frac{-3h}{hx(x+h)} \\ &= -3 \lim_{h \rightarrow 0} \frac{1}{x(x+h)} = -3 \cdot \frac{1}{x^2} = \boxed{-\frac{3}{x^2}}. \end{aligned}$$

6. Let $f(x) = 3x^2 + 2x$. Then

$$\begin{aligned} \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} &= \lim_{h \rightarrow 0} \frac{3(x+h)^2 + 2(x+h) - (3x^2 + 2x)}{h} \\ &= \lim_{h \rightarrow 0} \frac{3x^2 + 6xh + 3h^2 + 2x + 2h - 3x^2 - 2x}{h} \\ &= \lim_{h \rightarrow 0} \frac{6xh + 3h^2 + 2h}{h} = \lim_{h \rightarrow 0} (6x + 3h + 2) = \boxed{6x + 2}. \end{aligned}$$

7. Because $1 + \sin x \leq f(x) \leq |x| + 1$ for all x in the open interval $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$ containing 0 and

$$\lim_{x \rightarrow 0} (1 + \sin x) = 1 + \sin 0 = 1 \quad \text{and} \quad \lim_{x \rightarrow 0} (|x| + 1) = |0| + 1 = 1,$$

it follows from the Squeeze Theorem that

$$\lim_{x \rightarrow 0} f(x) = \boxed{1}.$$

$$8. \lim_{x \rightarrow 2} \left(2x - \frac{1}{x} \right) = 2(2) - \frac{1}{2} = \boxed{\frac{7}{2}}.$$

$$9. \lim_{x \rightarrow \pi} (x \cos x) = \pi \cos \pi = \boxed{-\pi}.$$

$$10. \lim_{x \rightarrow -1} (x^3 + 3x^2 - x - 1) = (-1)^3 + 3(-1)^2 - (-1) - 1 = \boxed{2}.$$

$$11. \lim_{x \rightarrow 0} \sqrt[3]{x(x+2)^3} = \sqrt[3]{0(2)^3} = \boxed{0}.$$

$$12. \lim_{x \rightarrow 0} [(2x+3)(x^5+5x)] = (0+3)(0^5+0) = \boxed{0}.$$

$$13. \lim_{x \rightarrow 3} \frac{x^3 - 27}{x - 3} = \lim_{x \rightarrow 3} \frac{(x-3)(x^2+3x+9)}{x-3} = \lim_{x \rightarrow 3} (x^2+3x+9) = 3^2 + 3(3) + 9 = \boxed{27}.$$

$$14. \lim_{x \rightarrow 3} \left(\frac{x^2}{x-3} - \frac{3x}{x-3} \right) = \lim_{x \rightarrow 3} \frac{x^2 - 3x}{x-3} = \lim_{x \rightarrow 3} \frac{x(x-3)}{x-3} = \lim_{x \rightarrow 3} x = \boxed{3}.$$

$$15. \lim_{x \rightarrow 2} \frac{x^2 - 4}{x - 2} = \lim_{x \rightarrow 2} \frac{(x-2)(x+2)}{x-2} = \lim_{x \rightarrow 2} (x+2) = 2+2 = \boxed{4}.$$

$$16. \lim_{x \rightarrow -1} \frac{x^2 + 3x + 2}{x^2 + 4x + 3} = \lim_{x \rightarrow -1} \frac{(x+1)(x+2)}{(x+1)(x+3)} = \lim_{x \rightarrow -1} \frac{x+2}{x+3} = \frac{-1+2}{-1+3} = \boxed{\frac{1}{2}}.$$

$$17. \lim_{x \rightarrow -2} \frac{x^3 + 5x^2 + 6x}{x^2 + x - 2} = \lim_{x \rightarrow -2} \frac{x(x+2)(x+3)}{(x+2)(x-1)} = \lim_{x \rightarrow -2} \frac{x(x+3)}{x-1} = \frac{-2(-2+3)}{-2-1} = \boxed{\frac{2}{3}}.$$

$$18. \lim_{x \rightarrow 1} \left(x^2 - 3x + \frac{1}{x} \right)^{15} = \left(1^2 - 3(1) + \frac{1}{1} \right)^{15} = (-1)^{15} = \boxed{-1}.$$

19.

$$\begin{aligned} \lim_{x \rightarrow 2} \frac{3 - \sqrt{x^2 + 5}}{x^2 - 4} &= \lim_{x \rightarrow 2} \frac{3 - \sqrt{x^2 + 5}}{x^2 - 4} \cdot \frac{3 + \sqrt{x^2 + 5}}{3 + \sqrt{x^2 + 5}} = \lim_{x \rightarrow 2} \frac{9 - (x^2 + 5)}{(x^2 - 4)(3 + \sqrt{x^2 + 5})} \\ &= \lim_{x \rightarrow 2} \frac{4 - x^2}{(x^2 - 4)(3 + \sqrt{x^2 + 5})} = -\lim_{x \rightarrow 2} \frac{1}{3 + \sqrt{x^2 + 5}} = -\frac{1}{3 + \sqrt{2^2 + 5}} = \boxed{-\frac{1}{6}}. \end{aligned}$$

20. Note that

$$\frac{1}{(2+x)^2} - \frac{1}{4} = \frac{4 - (2+x)^2}{4(2+x)^2} = \frac{4 - 4 - 4x - x^2}{4(2+x)^2} = -\frac{x(x+4)}{4(2+x)^2}.$$

Therefore,

$$\lim_{x \rightarrow 0} \left\{ \frac{1}{x} \left[\frac{1}{(2+x)^2} - \frac{1}{4} \right] \right\} = -\lim_{x \rightarrow 0} \left[\frac{1}{x} \cdot \frac{x(x+4)}{4(2+x)^2} \right] = -\lim_{x \rightarrow 0} \frac{x+4}{4(2+x)^2} = -\frac{0+4}{4(2+0)^2} = \boxed{-\frac{1}{4}}.$$

21.

$$\begin{aligned} \lim_{x \rightarrow 0} \frac{(x+3)^2 - 9}{x} &= \lim_{x \rightarrow 0} \frac{x^2 + 6x + 9 - 9}{x} \\ &= \lim_{x \rightarrow 0} \frac{x^2 + 6x}{x} = \lim_{x \rightarrow 0} \frac{x(x+6)}{x} = \lim_{x \rightarrow 0} (x+6) = 0+6 = \boxed{6}. \end{aligned}$$

$$22. \lim_{x \rightarrow 1} [(x^3 - 3x^2 + 3x - 1)(x+1)^2] = (1^3 - 3(1)^2 + 3(1) - 1)(1+1)^2 = 0(4) = \boxed{0}.$$

$$23. \lim_{x \rightarrow -2^+} \frac{x^2 + 5x + 6}{x + 2} = \lim_{x \rightarrow -2^+} \frac{(x+2)(x+3)}{x+2} = \lim_{x \rightarrow -2^+} (x+3) = -2+3 = \boxed{1}.$$

24. As x approaches 5 from the right, $x - 5 > 0$, so that

$$\lim_{x \rightarrow 5^+} \frac{|x - 5|}{x - 5} = \lim_{x \rightarrow 5^+} \frac{x - 5}{x - 5} = \lim_{x \rightarrow 5^+} 1 = \boxed{1}.$$

25. As x approaches 1 from the left, $x - 1 < 0$, so that

$$\lim_{x \rightarrow 1^-} \frac{|x - 1|}{x - 1} = \lim_{x \rightarrow 1^-} \frac{-(x - 1)}{x - 1} = \lim_{x \rightarrow 1^-} -1 = \boxed{-1}.$$

26. As x approaches $3/2$ from the right, $2x$ approaches 3 from the right, so that

$$\lim_{x \rightarrow 3/2^+} \lfloor 2x \rfloor = \boxed{3}.$$

$$27. \lim_{x \rightarrow 4^-} \frac{x^2 - 16}{x - 4} = \lim_{x \rightarrow 4^-} \frac{(x - 4)(x + 4)}{x - 4} = \lim_{x \rightarrow 4^-} (x + 4) = 4 + 4 = \boxed{8}.$$

28. As x approaches 1 from the right, $x - 1 > 0$, so that

$$\lim_{x \rightarrow 1^+} \sqrt{x - 1} = \sqrt{1 - 1} = \boxed{0}.$$

29. Because

$$\lim_{x \rightarrow 2^-} f(x) = \lim_{x \rightarrow 2^-} (2x + 3) = 2(2) + 3 = \boxed{7}$$

and

$$\lim_{x \rightarrow 2^+} f(x) = \lim_{x \rightarrow 2^+} (9 - x) = 9 - 2 = \boxed{7}$$

are equal, $\lim_{x \rightarrow 2} f(x)$ exists. Moreover, because both one-sided limits are equal to 7, $\boxed{\lim_{x \rightarrow 2} f(x) = 7}$.

30. Because

$$\lim_{x \rightarrow 3^-} f(x) = \lim_{x \rightarrow 3^-} (3x + 1) = 3(3) + 1 = \boxed{10}$$

and

$$\lim_{x \rightarrow 3^+} f(x) = \lim_{x \rightarrow 3^+} (4x - 2) = 4(3) - 2 = \boxed{10}$$

are equal, $\lim_{x \rightarrow 3} f(x)$ exists. Moreover, because both one-sided limits are equal to 10, $\boxed{\lim_{x \rightarrow 3} f(x) = 10}$.

31. The function f is defined at $c = 1$ with $f(1) = 5$. Because

$$\lim_{x \rightarrow 1^-} f(x) = \lim_{x \rightarrow 1^-} (5x - 2) = 5(1) - 2 = 3$$

and

$$\lim_{x \rightarrow 1^+} f(x) = \lim_{x \rightarrow 1^+} (2x + 1) = 2(1) + 1 = 3$$

are equal, $\lim_{x \rightarrow 1} f(x)$ exists and is equal to 3. However $f(1) = 5 \neq 3 = \lim_{x \rightarrow 1} f(x)$, so

$\boxed{f \text{ is not continuous at } c = 1}.$

32. The function f is defined at $c = -1$ with $f(-1) = 2$. Because

$$\lim_{x \rightarrow -1^-} f(x) = \lim_{x \rightarrow -1^-} x^2 = (-1)^2 = 1$$

and

$$\lim_{x \rightarrow -1^+} f(x) = \lim_{x \rightarrow -1^+} (-3x - 2) = -3(-1) - 2 = 1$$

are equal, $\lim_{x \rightarrow -1} f(x)$ exists and is equal to 1. However $f(-1) = 2 \neq 1 = \lim_{x \rightarrow -1} f(x)$, so

$\boxed{f \text{ is not continuous at } c = -1}.$

33. The function f is defined at $c = 0$ with $f(0) = 4$. Because

$$\lim_{x \rightarrow 0^-} f(x) = \lim_{x \rightarrow 0^-} (4 - 3x^2) = 4 - 3(0)^2 = 4$$

and

$$\lim_{x \rightarrow 0^+} f(x) = \lim_{x \rightarrow 0^+} \sqrt{16 - x^2} = \sqrt{16 - 0^2} = 4$$

are equal, $\lim_{x \rightarrow 0} f(x)$ exists and is equal to 4. Finally, $f(0) = \lim_{x \rightarrow 0} f(x)$, so $\boxed{f \text{ is continuous at } c = 0}$.

34. The function f is defined at $c = 4$ with $f(4) = \sqrt{4 + 4} = 2\sqrt{2}$. Because

$$\lim_{x \rightarrow 4^-} f(x) = \lim_{x \rightarrow 4^-} \sqrt{4 + x} = \sqrt{4 + 4} = 2\sqrt{2}$$

and

$$\lim_{x \rightarrow 4^+} f(x) = \lim_{x \rightarrow 4^+} \sqrt{\frac{x^2 - 16}{x - 4}} = \lim_{x \rightarrow 4^+} \sqrt{\frac{(x - 4)(x + 4)}{x - 4}} = \lim_{x \rightarrow 4^+} \sqrt{x + 4} = \sqrt{4 + 4} = 2\sqrt{2}$$

are equal, $\lim_{x \rightarrow 4} f(x)$ exists and is equal to $2\sqrt{2}$. Finally, $f(4) = \lim_{x \rightarrow 4} f(x)$, so $\boxed{f \text{ is continuous at } c = 4}$.

35. The function f is defined at $c = 1/2$ with $f(1/2) = \lfloor 1 \rfloor = 1$. As x approaches $1/2$ from the left, $2x$ approaches 1 from the left, so that

$$\lim_{x \rightarrow 1/2^-} f(x) = \lim_{x \rightarrow 1/2^-} \lfloor 2x \rfloor = 0.$$

On the other hand, as x approaches $1/2$ from the right, $2x$ approaches 1 from the right, so that

$$\lim_{x \rightarrow 1/2^+} f(x) = \lim_{x \rightarrow 1/2^+} \lfloor 2x \rfloor = 1.$$

Because the two one-sided limits as x approaches $1/2$ are not equal $\lim_{x \rightarrow 1/2} f(x)$ does not exist. Therefore,

$\boxed{f \text{ is not continuous at } c = 1/2}$.

36. The function f is defined at $c = 5$ with $f(5) = |5 - 5| = 0$. Because

$$\lim_{x \rightarrow 5^-} f(x) = \lim_{x \rightarrow 5^-} |x - 5| = \lim_{x \rightarrow 5^-} [-(x - 5)] = -(5 - 5) = 0$$

and

$$\lim_{x \rightarrow 5^+} f(x) = \lim_{x \rightarrow 5^+} |x - 5| = \lim_{x \rightarrow 5^+} (x - 5) = 5 - 5 = 0$$

are equal, $\lim_{x \rightarrow 5} f(x)$ exists and is equal to 0. Finally, $f(5) = \lim_{x \rightarrow 5} f(x)$, so $\boxed{f \text{ is continuous at } c = 5}$.

37. Let $f(x) = 2x^2 - 5x$.

(a) The average rate of change of f from 1 to x is

$$\frac{f(x) - f(1)}{x - 1} = \frac{2x^2 - 5x - (-3)}{x - 1} = \frac{2x^2 - 5x + 3}{x - 1} = \frac{(x - 1)(2x - 3)}{x - 1} = \boxed{2x - 3},$$

for $x \neq 1$.

(b) Using the result from part (a),

$$\lim_{x \rightarrow 1} \frac{f(x) - f(1)}{x - 1} = \lim_{x \rightarrow 1} (2x - 3) = 2(1) - 3 = \boxed{-1}.$$

38. The function

$$f(x) = \begin{cases} -1, & \text{if } -1 \leq x \leq 0 \\ 1, & \text{if } 0 < x \leq 1 \end{cases}$$

satisfies the indicated conditions: f is continuous on the interval $[-1, 1]$ except at 0, $f(-1) = -1 < 0$, $f(1) = 1 > 0$, and f has no zeroes. This does not contradict the Intermediate Value Theorem because the function is not continuous on the closed interval $[-1, 1]$.

39. Let
- $g(x) = x$
- and
- $h(x) = x^3 - 27$
- . The polynomial functions
- g
- and
- h
- are both continuous on the set of all real numbers. Because
- f
- is the quotient of
- g
- and
- h
- ,
- f
- is continuous on the set of all real numbers except those for which
- $h(x) = 0$
- . The only real solution to the equation

$$h(x) = x^3 - 27 = (x - 3)(x^2 + 3x + 9) = 0$$

is $x = 3$, so f is continuous on the set $\{x|x \neq 3\}$.

40. Let
- $g(x) = x^2 - 3$
- and
- $h(x) = x^2 + 5x + 6$
- . The polynomial functions
- g
- and
- h
- are both continuous on the set of all real numbers. Because
- f
- is the quotient of
- g
- and
- h
- ,
- f
- is continuous on the set of all real numbers except those for which
- $h(x) = 0$
- . The solutions to the equation
- $h(x) = x^2 + 5x + 6 = (x + 3)(x + 2) = 0$
- are
- $x = -3$
- and
- $x = -2$
- , so
- f is continuous on the set $\{x|x \neq -3, x \neq -2\}$
- .

41. Let
- $g(x) = 2x + 1$
- and
- $h(x) = x^3 + 4x^2 + 4x$
- . The polynomial functions
- g
- and
- h
- are both continuous on the set of all real numbers. Because
- f
- is the quotient of
- g
- and
- h
- ,
- f
- is continuous on the set of all real numbers except those for which
- $h(x) = 0$
- . The solutions to the equation
- $h(x) = x^3 + 4x^2 + 4x = x(x + 2)^2 = 0$
- are
- $x = -2$
- and
- $x = 0$
- , so
- f is continuous on the set $\{x|x \neq -2, x \neq 0\}$
- .

42. Let
- $g(x) = \sqrt{x}$
- and
- $h(x) = x - 1$
- . The function
- g
- is continuous on the set
- $\{x|x \geq 0\}$
- , and the polynomial function
- h
- is the continuous on the set of all real numbers. Moreover, the solution of the inequality
- $h(x) \geq 0$
- is the set
- $\{x|x \geq 1\}$
- . As
- f
- is the composition
- $g(h(x))$
- , the function
- f
- is continuous at
- c
- provided
- h
- is continuous at
- c
- and
- g
- is continuous at
- $h(c)$
- ; thus,
- f is continuous on the set $\{x|x \geq 1\}$
- .

43. Let
- $g(x) = 2^x$
- and
- $h(x) = -x$
- . The exponential function
- g
- and the polynomial function
- h
- are both continuous on the set of all real numbers. As
- f
- is the composition
- $g(h(x))$
- , the function
- f
- is continuous at
- c
- provided
- h
- is continuous at
- c
- and
- g
- is continuous at
- $h(c)$
- ;
- f is continuous on the set of all real numbers
- .

44. Let
- $f(x) = 2x^3 + 3x^2 - 23x - 42$
- . This polynomial function is continuous on the set of all real numbers, so it is continuous on the closed interval
- $[3, 4]$
- . Because

$$f(3) = 2(3)^3 + 3(3)^2 - 23(3) - 42 = -30 < 0$$

and

$$f(4) = 2(4)^3 + 3(4)^2 - 23(4) - 42 = 42 > 0,$$

the Intermediate Value Theorem guarantees there is a number c in the interval $(3, 4)$ such that $f(c) = 0$. Thus, the equation $2x^3 + 3x^2 - 23x - 42 = 0$ does have a solution in the interval $(3, 4)$.

45. The polynomial function
- $f(x) = 8x^4 - 2x^2 + 5x - 1$
- is continuous for all real numbers, so it is continuous on the closed interval
- $[0, 1]$
- . Because
- $f(0) = -1 < 0$
- and
- $f(1) = 8 - 2 + 5 - 1 = 10 > 0$
- , the Intermediate Value Theorem guarantees that
- f
- must have a zero on the interval
- $(0, 1)$
- . To approximate this zero, subdivide the interval
- $[0, 1]$
- into 10 subintervals, each of length 0.1, and evaluate
- f
- at each endpoint. The results are shown in the first two columns of the table below. Because
- $f(0.2) = -0.0672 < 0$
- and
- $f(0.3) = 0.3848 > 0$
- , the Intermediate Value Theorem guarantees the zero lies in the interval
- $(0.2, 0.3)$
- . Repeating the process by subdividing the interval
- $[0.2, 0.3]$
- into 10 subintervals of length 0.01 yields the results in the middle two columns of the table, where the function values have been rounded to five decimal places for display purposes. The zero has now been bracketed in the interval
- $(0.21, 0.22)$
- . Repeating the subdivision process once more, the results in the last two columns of the

table are produced, again with the function values rounded to five decimal places. Examining the function values in the last column, it follows that the zero of the function f is $\boxed{0.215}$, correct to three decimal places.

$[0, 1]$		$[0.2, 0.3]$		$[0.21, 0.22]$	
x	$f(x)$	x	$f(x)$	x	$f(x)$
0.0	-1.0000	0.20	-0.06720	0.210	-0.02264

46. The polynomial function $f(x) = 3x^3 - 10x + 9$ is continuous for all real numbers, so it is continuous on the closed interval $[-3, -2]$. Because $f(-3) = 3(-3)^3 - 10(-3) + 9 = -42 < 0$ and $f(-2) = 3(-2)^3 - 10(-2) + 9 = 5 > 0$, the Intermediate Value Theorem guarantees that f must have a zero on the interval $(-3, -2)$. To approximate this zero, subdivide the interval $[-3, -2]$ into 10 subintervals, each of length 0.1, and evaluate f at each endpoint. The results are shown in the first two columns of the table below. Because $f(-2.2) = -0.944 < 0$ and $f(-2.1) = 2.217 > 0$, the Intermediate Value Theorem guarantees the zero lies in the interval $(-2.2, -2.1)$. Repeating the process by subdividing the interval $[-2.2, -2.1]$ into 10 subintervals of length 0.01 yields the results in the middle two columns of the table, where the function values have been rounded to five decimal places for display purposes. The zero has now been bracketed in the interval $(-2.18, -2.17)$. Repeating the subdivision process once more, the results in the last two columns of the table are produced, again with the function values rounded to five decimal places. Examining the function values in the last column, it follows that the zero of the function f is $\boxed{-2.171}$, correct to three decimal places.

$[-3, -2]$		$[-2.2, -2.1]$		$[-2.18, -2.17]$	
x	$f(x)$	x	$f(x)$	x	$f(x)$
-3.0	-42.000	-2.20	-0.94400	-2.180	-0.28070
-2.9	-35.167	-2.19	-0.61038	-2.179	-0.24794
-2.8	-28.856	-2.18	-0.28070	-2.178	-0.21523
-2.7	-23.049	-2.17	0.04506	-2.177	-0.18256
-2.6	-17.728	-2.16	0.36691	-2.176	-0.14992
-2.5	-12.875	-2.15	0.68488	-2.175	-0.11733

-2.1	2.217	-2.11	1.91821	-2.171	0.01266
-2.0	5.000	-2.10	2.21700	-2.170	0.04506

47. For $x > 0$, $|x| = x$, so

$$\lim_{x \rightarrow 0^+} \frac{|x|}{x}(1-x) = \lim_{x \rightarrow 0^+} \frac{x}{x}(1-x) = \lim_{x \rightarrow 0^+} (1-x) = 1-0 = \boxed{1}.$$

For $x < 0$, $|x| = -x$, so

$$\lim_{x \rightarrow 0^-} \frac{|x|}{x}(1-x) = \lim_{x \rightarrow 0^-} \frac{-x}{x}(1-x) = \lim_{x \rightarrow 0^-} (x-1) = 0-1 = \boxed{-1}.$$

Because the two one-sided limits as x approaches 0 are not equal, $\lim_{x \rightarrow 0} \frac{|x|}{x}(1-x)$ does not exist.

$$48. \lim_{x \rightarrow 2} \left(\frac{x^2}{x-2} - \frac{2x}{x-2} \right) = \lim_{x \rightarrow 2} \frac{x^2 - 2x}{x-2} = \lim_{x \rightarrow 2} \frac{x(x-2)}{x-2} = \lim_{x \rightarrow 2} x = \boxed{2}.$$

Individually, the functions

$$\frac{x^2}{x-2} \quad \text{and} \quad \frac{2x}{x-2}$$

become unbounded as x approaches 2, so that neither of the individual limits exists. Because the individual limits do not exist, the Limit of a Sum property does not apply, and

$$\lim_{x \rightarrow 2} \left(\frac{x^2}{x-2} - \frac{2x}{x-2} \right) \quad \text{is not given by} \quad \lim_{x \rightarrow 2} \frac{x^2}{x-2} - \lim_{x \rightarrow 2} \frac{2x}{x-2}.$$

49. Let $f(x) = \sqrt{x}$. Then

$$\begin{aligned} \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} &= \lim_{h \rightarrow 0} \frac{\sqrt{x+h} - \sqrt{x}}{h} = \lim_{h \rightarrow 0} \frac{\sqrt{x+h} - \sqrt{x}}{h} \cdot \frac{\sqrt{x+h} + \sqrt{x}}{\sqrt{x+h} + \sqrt{x}} \\ &= \lim_{h \rightarrow 0} \frac{(x+h) - x}{h(\sqrt{x+h} + \sqrt{x})} = \lim_{h \rightarrow 0} \frac{1}{\sqrt{x+h} + \sqrt{x}} = \frac{1}{\sqrt{x} + \sqrt{x}} = \boxed{\frac{1}{2\sqrt{x}}}. \end{aligned}$$

50. To make

$$|(2x+1) - 7| = |2x-6| = 2|x-3| < 0.01,$$

requires that $|x-3| < 0.005$. Thus, the largest δ that “works” for $\epsilon = 0.01$ is $\boxed{\delta = 0.005}$.

$$51. \lim_{x \rightarrow 0} \cos(\tan x) = \cos(\tan 0) = \cos 0 = \boxed{1}.$$

$$52. \lim_{x \rightarrow 0} \frac{\sin \frac{x}{4}}{x} = \lim_{x \rightarrow 0} \frac{\frac{1}{4} \sin \frac{x}{4}}{\frac{x}{4}} = \frac{1}{4} \lim_{x \rightarrow 0} \frac{\sin \frac{x}{4}}{\frac{x}{4}} = \frac{1}{4} \cdot 1 = \boxed{\frac{1}{4}}.$$

53.

$$\begin{aligned} \lim_{x \rightarrow 0} \frac{\tan(3x)}{\tan(4x)} &= \lim_{x \rightarrow 0} \frac{\sin(3x)}{\sin(4x)} \cdot \frac{\cos(4x)}{\cos(3x)} = \lim_{x \rightarrow 0} \frac{\frac{3 \sin(3x)}{3x}}{\frac{4 \sin(4x)}{4x}} \cdot \lim_{x \rightarrow 0} \frac{\cos(4x)}{\cos(3x)} \\ &= \frac{3 \lim_{x \rightarrow 0} \frac{\sin(3x)}{3x}}{4 \lim_{x \rightarrow 0} \frac{\sin(4x)}{4x}} \cdot \frac{\cos 0}{\cos 0} = \frac{3}{4} \cdot \frac{1}{1} \cdot \frac{1}{1} = \boxed{\frac{3}{4}}. \end{aligned}$$

$$54. \lim_{x \rightarrow 0} \frac{\cos \frac{x}{3} - 1}{x} = \lim_{x \rightarrow 0} \frac{\frac{1}{3} (\cos \frac{x}{3} - 1)}{\frac{x}{3}} = \frac{1}{3} \lim_{x \rightarrow 0} \frac{\cos \frac{x}{3} - 1}{\frac{x}{3}} = \frac{1}{3} \cdot 0 = \boxed{0}.$$

$$55. \lim_{x \rightarrow 0} \left(\frac{\cos x - 1}{x} \right)^{10} = \left(\lim_{x \rightarrow 0} \frac{\cos x - 1}{x} \right)^{10} = 0^{10} = \boxed{0}.$$

56.

$$\begin{aligned} \lim_{x \rightarrow 0} \frac{e^{4x} - 1}{e^x - 1} &= \lim_{x \rightarrow 0} \frac{(e^{2x} - 1)(e^{2x} + 1)}{e^x - 1} = \lim_{x \rightarrow 0} \frac{(e^x - 1)(e^x + 1)(e^{2x} + 1)}{e^x - 1} \\ &= \lim_{x \rightarrow 0} [(e^x + 1)(e^{2x} + 1)] = (e^0 + 1)(e^0 + 1) = \boxed{4}. \end{aligned}$$

57. As x approaches $\pi/2$ from the right, $\sin x$ approaches 1 and $\cos x$ approaches 0 from the left. Thus, $\tan x = \frac{\sin x}{\cos x}$ becomes unbounded in the negative direction, so that

$$\lim_{x \rightarrow \pi/2^+} \tan x = \boxed{-\infty}.$$

58. As x approaches -3 , $2 + x$ approaches -1 and $(x + 3)^2$ approaches 0 from the right. Thus, $\frac{2 + x}{(x + 3)^2}$ becomes unbounded in the negative direction, so that

$$\lim_{x \rightarrow -3} \frac{2 + x}{(x + 3)^2} = \boxed{-\infty}.$$

$$59. \lim_{x \rightarrow \infty} \frac{3x^3 - 2x + 1}{x^3 - 8} = \lim_{x \rightarrow \infty} \frac{\frac{3x^3 - 2x + 1}{x^3}}{\frac{x^3 - 8}{x^3}} = \lim_{x \rightarrow \infty} \frac{3 - \frac{2}{x^2} + \frac{1}{x^3}}{1 - \frac{8}{x^3}} = \frac{3 - 0 + 0}{1 - 0} = \boxed{3}.$$

$$60. \lim_{x \rightarrow \infty} \frac{3x^4 + x}{2x^2} = \lim_{x \rightarrow \infty} \left(\frac{3}{2}x^2 + \frac{1}{2x} \right) = \boxed{\infty}.$$

61. The domain of the rational function $f(x) = \frac{4x - 2}{x + 3}$ is the set $\{x | x \neq -3\}$. The one-sided limits as x approaches -3 are

$$\lim_{x \rightarrow -3^-} \frac{4x - 2}{x + 3} = \infty \quad \text{and} \quad \lim_{x \rightarrow -3^+} \frac{4x - 2}{x + 3} = -\infty,$$

so $\boxed{x = -3 \text{ is a vertical asymptote of the graph of } f}$. Moreover, because

$$\lim_{x \rightarrow -\infty} \frac{4x - 2}{x + 3} = \lim_{x \rightarrow -\infty} \frac{\frac{4x - 2}{x}}{\frac{x + 3}{x}} = \lim_{x \rightarrow -\infty} \frac{4 - \frac{2}{x}}{1 + \frac{3}{x}} = \frac{4 - 0}{1 + 0} = 4$$

and

$$\lim_{x \rightarrow \infty} \frac{4x - 2}{x + 3} = \lim_{x \rightarrow \infty} \frac{\frac{4x - 2}{x}}{\frac{x + 3}{x}} = \lim_{x \rightarrow \infty} \frac{4 - \frac{2}{x}}{1 + \frac{3}{x}} = \frac{4 - 0}{1 + 0} = 4,$$

$\boxed{y = 4 \text{ is a horizontal asymptote of the graph of } f}$.

62. The domain of the rational function $f(x) = \frac{2x}{x^2 - 4}$ is the set $\{x | x \neq \pm 2\}$. The one-sided limits as x approaches -2 are

$$\lim_{x \rightarrow -2^-} \frac{2x}{x^2 - 4} = -\infty \quad \text{and} \quad \lim_{x \rightarrow -2^+} \frac{2x}{x^2 - 4} = \infty,$$

so $\boxed{x = -2 \text{ is a vertical asymptote of the graph of } f}$. The one-sided limits as x approaches 2 are

$$\lim_{x \rightarrow 2^-} \frac{2x}{x^2 - 4} = -\infty \quad \text{and} \quad \lim_{x \rightarrow 2^+} \frac{2x}{x^2 - 4} = \infty,$$

so $\boxed{x = 2 \text{ is also a vertical asymptote of the graph of } f}$. Moreover, because

$$\lim_{x \rightarrow -\infty} \frac{2x}{x^2 - 4} = \lim_{x \rightarrow -\infty} \frac{\frac{2x}{x^2}}{\frac{x^2 - 4}{x^2}} = \lim_{x \rightarrow -\infty} \frac{\frac{2}{x}}{1 - \frac{4}{x^2}} = \frac{0}{1 - 0} = 0$$

and

$$\lim_{x \rightarrow \infty} \frac{2x}{x^2 - 4} = \lim_{x \rightarrow \infty} \frac{\frac{2x}{x^2}}{\frac{x^2 - 4}{x^2}} = \lim_{x \rightarrow \infty} \frac{\frac{2}{x}}{1 - \frac{4}{x^2}} = \frac{0}{1 - 0} = 0,$$

$y = 0$ is a horizontal asymptote of the graph of f .

63. The function f is defined at 0 with $f(0) = 1/2$. Because

$$\begin{aligned} \lim_{x \rightarrow 0} f(x) &= \lim_{x \rightarrow 0} \frac{\tan x}{2x} = \frac{1}{2} \lim_{x \rightarrow 0} \frac{\sin x}{x} \cdot \frac{1}{\cos x} \\ &= \frac{1}{2} \lim_{x \rightarrow 0} \frac{\sin x}{x} \cdot \lim_{x \rightarrow 0} \frac{1}{\cos x} = \frac{1}{2} \cdot 1 \cdot \frac{1}{1} = \frac{1}{2}, \end{aligned}$$

it follows that $\lim_{x \rightarrow 0} f(x)$ exists and $f(0) = \lim_{x \rightarrow 0} f(x)$. Therefore, f is continuous at 0.

64. The function f is defined at 0 with $f(0) = 1$. Because

$$\lim_{x \rightarrow 0} f(x) = \lim_{x \rightarrow 0} \frac{\sin(3x)}{x} = \lim_{x \rightarrow 0} \frac{3 \sin(3x)}{3x} = 3 \lim_{x \rightarrow 0} \frac{\sin(3x)}{3x} = 3 \cdot 1 = 3,$$

it follows that $\lim_{x \rightarrow 0} f(x)$ exists but $f(0) \neq \lim_{x \rightarrow 0} f(x)$. Therefore, f is not continuous at 0.

65. Note that

$$\cos\left(\pi x + \frac{\pi}{2}\right) = \cos(\pi x) \cos \frac{\pi}{2} - \sin(\pi x) \sin \frac{\pi}{2} = \cos(\pi x) \cdot 0 - \sin(\pi x) \cdot 1 = -\sin(\pi x).$$

Thus,

$$\lim_{x \rightarrow 0} f(x) = -\lim_{x \rightarrow 0} \frac{\sin(\pi x)}{x} = -\lim_{x \rightarrow 0} \frac{\pi \sin(\pi x)}{\pi x} = -\pi \lim_{x \rightarrow 0} \frac{\sin(\pi x)}{\pi x} = -\pi \cdot 1 = -\pi.$$

To make f continuous at 0, define $f(0) = -\pi$.

66. Take $\epsilon = 1$, let $\delta > 0$, and choose any x satisfying $0 < |x + 3| < \delta$. Then

$$|(x^2 - 9) - (-18)| = |x^2 + 9| = x^2 + 9 \geq 9 > 1 = \epsilon,$$

so that $\lim_{x \rightarrow -3} (x^2 - 9) \neq -18$.

67. (a) Answers will vary. The figure below displays the graph of a function f with the properties

$$f(-1) = 0, \quad \lim_{x \rightarrow \infty} f(x) = 2, \quad \lim_{x \rightarrow -\infty} f(x) = 2, \quad \lim_{x \rightarrow 4^-} f(x) = -\infty, \quad \text{and} \quad \lim_{x \rightarrow 4^+} f(x) = \infty.$$

(b) Answers will vary. The function shown above is $f(x) = \frac{2x+2}{x-4}$.

68. (a) Let $R(x) = \frac{2x^2 - 5x + 2}{5x^2 - x - 2}$. Factoring the numerator yields

$$2x^2 - 5x + 2 = (2x - 1)(x - 2).$$

Applying the quadratic formula to the equation $5x^2 - x - 2 = 0$ yields

$$x = \frac{1 \pm \sqrt{(-1)^2 - 4(5)(-2)}}{2(5)} = \frac{1 \pm \sqrt{41}}{10}.$$

Therefore, the domain of R is the set $\left\{x \mid x \neq \frac{1 \pm \sqrt{41}}{10}\right\}$, the x -intercepts are $\frac{1}{2}$ and 2 , and the y -intercept is $R(0) = -1$.

(b) The one-sided limits as x approaches $\frac{1 - \sqrt{41}}{10} \approx -0.54$ are

$$\lim_{x \rightarrow \frac{1 - \sqrt{41}}{10}^-} R(x) = \infty \quad \text{and} \quad \lim_{x \rightarrow \frac{1 - \sqrt{41}}{10}^+} R(x) = -\infty.$$

Thus, the graph of R becomes unbounded in the positive direction as x approaches $\frac{1 - \sqrt{41}}{10}$ from the left and becomes unbounded in the negative direction as x approaches $\frac{1 - \sqrt{41}}{10}$ from the right. The one-sided limits as x approaches $\frac{1 + \sqrt{41}}{10} \approx 0.74$ are

$$\lim_{x \rightarrow \frac{1 + \sqrt{41}}{10}^-} R(x) = \infty \quad \text{and} \quad \lim_{x \rightarrow \frac{1 + \sqrt{41}}{10}^+} R(x) = -\infty.$$

Thus, the graph of R becomes unbounded in the positive direction as x approaches $\frac{1 + \sqrt{41}}{10}$ from the left and becomes unbounded in the negative direction as x approaches $\frac{1 + \sqrt{41}}{10}$ from the right.

(c) Based on the limits from part (b), $x = \frac{1 - \sqrt{41}}{10}$ and $x = \frac{1 + \sqrt{41}}{10}$ are both vertical asymptotes of the graph of R . Because

$$\lim_{x \rightarrow -\infty} \frac{2x^2 - 5x + 2}{5x^2 - x - 2} = \lim_{x \rightarrow -\infty} \frac{\frac{2x^2 - 5x + 2}{5x^2}}{\frac{5x^2 - x - 2}{5x^2}} = \lim_{x \rightarrow -\infty} \frac{\frac{2}{5} - \frac{1}{x} + \frac{2}{2x^2}}{1 - \frac{1}{5x} - \frac{2}{5x^2}} = \frac{\frac{2}{5} - 0 + 0}{1 - 0 - 0} = \frac{2}{5}$$

and

$$\lim_{x \rightarrow \infty} \frac{2x^2 - 5x + 2}{5x^2 - x - 2} = \lim_{x \rightarrow \infty} \frac{\frac{2x^2 - 5x + 2}{5x^2}}{\frac{5x^2 - x - 2}{5x^2}} = \lim_{x \rightarrow \infty} \frac{\frac{2}{5} - \frac{1}{x} + \frac{2}{2x^2}}{1 - \frac{1}{5x} - \frac{2}{5x^2}} = \frac{\frac{2}{5} - 0 + 0}{1 - 0 - 0} = \frac{2}{5},$$

$y = \frac{2}{5}$ is a horizontal asymptote of the graph of R .

69. Because $1 - x^2 \leq f(x) \leq \cos x$ for all x in the open interval $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$ containing 0 and

$$\lim_{x \rightarrow 0} (1 - x^2) = 1 - 0 = 1 \quad \text{and} \quad \lim_{x \rightarrow 0} \cos x = \cos 0 = 1,$$

it follows from the Squeeze Theorem that

$$\lim_{x \rightarrow 0} f(x) = 1.$$

Chapter 3: More About Derivatives

3.1: The Chain Rule

Concepts and Vocabulary

1. The derivative of a composite function $(f \circ g)(x)$ can be found using the **Chain** Rule.
2. **True**. If $y = f(u)$ and $u = g(x)$ are differentiable functions, then $y = f(g(x))$ is differentiable.
3. **False**. If $y = f(g(x))$ is a differentiable function, then $y' = f'(g(x))g'(x)$, by the Chain Rule.
4. To find the derivative of $y = \tan(1 + \cos x)$, using the Chain Rule, begin with $y = \tan u$ and $u = 1 + \cos x$.
5. If $y = (x^3 + 4x + 1)^{100}$, then

$$y' = 100(x^3 + 4x + 1)^{100-1} \cdot \frac{d}{dx}(x^3 + 4x + 1) = 100(x^3 + 4x + 1)^{99}(3x^2 + 4).$$

6. If $f(x) = e^{3x^2+5}$, then $f'(x) = e^{3x^2+5} \cdot \frac{d}{dx}(3x^2 + 5) = 6xe^{3x^2+5}$.
7. **True**. The Chain Rule can be applied to multiple composite functions.
8. $\frac{d}{dx} \sin x^2 = \cos x^2 \cdot \frac{d}{dx} x^2 = 2x \cos x^2$.

Skill Building

9. Let $y = u^5$ and $u = x^3 + 1$. Then $y = (x^3 + 1)^5$. Moreover,

$$\frac{dy}{du} = \frac{d}{du} u^5 = 5u^4 = 5(x^3 + 1)^4 \quad \text{and} \quad \frac{du}{dx} = \frac{d}{dx}(x^3 + 1) = 3x^2,$$

so, by the Chain Rule,

$$\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx} = 5(x^3 + 1)^4 \cdot 3x^2 = 15x^2(x^3 + 1)^4.$$

10. Let $y = u^3$ and $u = 2x + 5$. Then $y = (2x + 5)^3$. Moreover,

$$\frac{dy}{du} = \frac{d}{du} u^3 = 3u^2 = 3(2x + 5)^2 \quad \text{and} \quad \frac{du}{dx} = \frac{d}{dx}(2x + 5) = 2,$$

so, by the Chain Rule,

$$\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx} = 3(2x + 5)^2 \cdot 2 = 6(2x + 5)^2.$$

11. Let $y = \frac{u}{u+1}$ and $u = x^2 + 1$. Then $y = \frac{x^2 + 1}{(x^2 + 1) + 1} = \frac{x^2 + 1}{x^2 + 2}$. Moreover,

$$\frac{dy}{du} = \frac{d}{du} \left(\frac{u}{u+1} \right) = \frac{(u+1)(1) - u(1)}{(u+1)^2} = \frac{1}{(u+1)^2} = \frac{1}{(x^2 + 2)^2}$$

and

$$\frac{du}{dx} = \frac{d}{dx}(x^2 + 1) = 2x,$$

so, by the Chain Rule,

$$\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx} = \frac{1}{(x^2 + 2)^2} \cdot 2x = \boxed{\frac{2x}{(x^2 + 2)^2}}.$$

12. Let $y = \frac{u-1}{u}$ and $u = x^2 - 1$. Then $y = \frac{(x^2 - 1) - 1}{x^2 - 1} = \frac{x^2 - 2}{x^2 - 1}$. Moreover,

$$\frac{dy}{du} = \frac{d}{du} \left(\frac{u-1}{u} \right) = \frac{u(1) - (u-1)(1)}{u^2} = \frac{1}{u^2} = \frac{1}{(x^2 - 1)^2}$$

and

$$\frac{du}{dx} = \frac{d}{dx}(x^2 - 1) = 2x,$$

so, by the Chain Rule,

$$\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx} = \frac{1}{(x^2 - 1)^2} \cdot 2x = \boxed{\frac{2x}{(x^2 - 1)^2}}.$$

13. Let $y = (u+1)^2$ and $u = \frac{1}{x}$. Then $y = \left(\frac{1}{x} + 1\right)^2$. Moreover,

$$\begin{aligned} \frac{dy}{du} &= \frac{d}{du}(u+1)^2 = 2(u+1)^{2-1} \cdot \frac{d}{du}(u+1) \\ &= 2(u+1) \cdot 1 = 2(u+1) = 2\left(\frac{1}{x} + 1\right) \end{aligned}$$

and

$$\frac{du}{dx} = \frac{d}{dx}\left(\frac{1}{x}\right) = -\frac{1}{x^2},$$

so, by the Chain Rule

$$\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx} = \left[2\left(\frac{1}{x} + 1\right) \cdot \left(-\frac{1}{x^2}\right) \right].$$

14. Let $y = (u^2 - 1)^3$ and $u = \frac{1}{x+2}$. Then

$$y = \left[\left(\frac{1}{x+2} \right)^2 - 1 \right]^3 = \left(\frac{1}{(x+2)^2} - 1 \right)^3.$$

Moreover,

$$\begin{aligned} \frac{dy}{du} &= \frac{d}{du}(u^2 - 1)^3 = 3(u^2 - 1)^{3-1} \cdot \frac{d}{du}(u^2 - 1) \\ &= 3(u^2 - 1)^2 \cdot 2u = 6u(u^2 - 1)^2 = \frac{6}{x+2} \left(\frac{1}{(x+2)^2} - 1 \right)^2 \end{aligned}$$

and

$$\frac{du}{dx} = \frac{d}{dx} \left(\frac{1}{x+2} \right) = \frac{(x+2)(0) - 1(1)}{(x+2)^2} = -\frac{1}{(x+2)^2},$$

so, by the Chain Rule

$$\begin{aligned} \frac{dy}{dx} &= \frac{dy}{du} \cdot \frac{du}{dx} = \frac{6}{x+2} \left(\frac{1}{(x+2)^2} - 1 \right)^2 \cdot \left(-\frac{1}{(x+2)^2} \right) \\ &= \boxed{-\frac{6}{(x+2)^3} \left(\frac{1}{(x+2)^2} - 1 \right)^2}. \end{aligned}$$

15. Let $f(x) = (3x + 5)^2$. Then

$$\frac{df}{dx} = \frac{d}{dx}(3x + 5)^2 = 2(3x + 5)^{2-1} \cdot \frac{d}{dx}(3x + 5) = 2(3x + 5) \cdot 3 = \boxed{6(3x + 5)}.$$

16. Let $f(x) = (2x - 5)^3$. Then

$$\frac{df}{dx} = \frac{d}{dx}(2x - 5)^3 = 3(2x - 5)^{3-1} \cdot \frac{d}{dx}(2x - 5) = 3(2x - 5)^2 \cdot 2 = \boxed{6(2x - 5)^2}.$$

17. Let $f(x) = (6x - 5)^{-3}$. Then

$$\frac{df}{dx} = \frac{d}{dx}(6x - 5)^{-3} = -3(6x - 5)^{-3-1} \cdot \frac{d}{dx}(6x - 5) = -3(6x - 5)^{-4} \cdot 6 = \boxed{-\frac{18}{(6x - 5)^4}}.$$

18. Let $f(t) = (4t + 1)^{-2}$. Then

$$\frac{df}{dt} = \frac{d}{dt}(4t + 1)^{-2} = -2(4t + 1)^{-2-1} \cdot \frac{d}{dt}(4t + 1) = -2(4t + 1)^{-3} \cdot 4 = \boxed{-\frac{8}{(4t + 1)^3}}.$$

19. Let $g(x) = (x^2 + 5)^4$. Then

$$\frac{dg}{dx} = \frac{d}{dx}(x^2 + 5)^4 = 4(x^2 + 5)^{4-1} \cdot \frac{d}{dx}(x^2 + 5) = 4(x^2 + 5)^3 \cdot 2x = \boxed{8x(x^2 + 5)^3}.$$

20. Let $F(x) = (x^3 - 2)^5$. Then

$$\frac{dF}{dx} = \frac{d}{dx}(x^3 - 2)^5 = 5(x^3 - 2)^{5-1} \cdot \frac{d}{dx}(x^3 - 2) = 5(x^3 - 2)^4 \cdot 3x^2 = \boxed{15x^2(x^3 - 2)^4}.$$

21. Let $f(u) = \left(u - \frac{1}{u}\right)^3$. Then

$$\frac{df}{du} = \frac{d}{du} \left(u - \frac{1}{u}\right)^3 = 3 \left(u - \frac{1}{u}\right)^{3-1} \cdot \frac{d}{du} \left(u - \frac{1}{u}\right) = \boxed{3 \left(u - \frac{1}{u}\right)^2 \left(1 + \frac{1}{u^2}\right)}.$$

22. Let $f(x) = \left(x + \frac{1}{x}\right)^3$. Then

$$\frac{df}{dx} = \frac{d}{dx} \left(x + \frac{1}{x}\right)^3 = 3 \left(x + \frac{1}{x}\right)^{3-1} \cdot \frac{d}{dx} \left(x + \frac{1}{x}\right) = \boxed{3 \left(x + \frac{1}{x}\right)^2 \left(1 - \frac{1}{x^2}\right)}.$$

23. Let $g(x) = (4x + e^x)^3$. Then

$$\frac{dg}{dx} = \frac{d}{dx}(4x + e^x)^3 = 3(4x + e^x)^{3-1} \cdot \frac{d}{dx}(4x + e^x) = \boxed{3(4x + e^x)^2(4 + e^x)}.$$

24. Let $F(x) = (e^x - x^2)^2$. Then

$$\frac{dF}{dx} = \frac{d}{dx}(e^x - x^2)^2 = 2(e^x - x^2)^{2-1} \cdot \frac{d}{dx}(e^x - x^2) = \boxed{2(e^x - x^2)(e^x - 2x)}.$$

25. Let $f(x) = \tan^2 x = (\tan x)^2$. Then

$$\frac{df}{dx} = \frac{d}{dx} \tan^2 x = 2 \tan^{2-1} x \cdot \frac{d}{dx} \tan x = \boxed{2 \tan x \sec^2 x}.$$

26. Let $f(x) = \sec^3 x = (\sec x)^3$. Then

$$\frac{df}{dx} = \frac{d}{dx} \sec^3 x = 3 \sec^{3-1} x \cdot \frac{d}{dx} \sec x = 3 \sec^2 x \cdot \sec x \tan x = \boxed{3 \sec^3 x \tan x}.$$

27. Let $f(z) = (\tan z + \cos z)^2$. Then

$$\begin{aligned} \frac{df}{dz} &= \frac{d}{dz} (\tan z + \cos z)^2 = 2(\tan z + \cos z)^{2-1} \cdot \frac{d}{dz} (\tan z + \cos z) \\ &= \boxed{2(\tan z + \cos z)(\sec^2 z - \sin z)}. \end{aligned}$$

28. Let $f(z) = (e^z + 2 \sin z)^3$. Then

$$\begin{aligned} \frac{df}{dz} &= \frac{d}{dz} (e^z + 2 \sin z)^3 = 3(e^z + 2 \sin z)^{3-1} \cdot \frac{d}{dz} (e^z + 2 \sin z) \\ &= 3(e^z + 2 \sin z)^2 \cdot (e^z + 2 \cos z) = \boxed{3(e^z + 2 \cos z)(e^z + 2 \sin z)^2}. \end{aligned}$$

29. Let $y = (x^2 + 4)^2(2x^3 - 1)^3$. Then

$$\begin{aligned} \frac{dy}{dx} &= \frac{d}{dx} [(x^2 + 4)^2(2x^3 - 1)^3] = (x^2 + 4)^2 \frac{d}{dx} (2x^3 - 1)^3 + (2x^3 - 1)^3 \frac{d}{dx} (x^2 + 4)^2 \\ &= (x^2 + 4)^2 \cdot 3(2x^3 - 1)^{3-1} \cdot \frac{d}{dx} (2x^3 - 1) + (2x^3 - 1)^3 \cdot 2(x^2 + 4)^{2-1} \cdot \frac{d}{dx} (x^2 + 4) \\ &= 3(x^2 + 4)^2 (2x^3 - 1)^2 \cdot 6x^2 + 2(x^2 + 4)(2x^3 - 1)^3 \cdot 2x \\ &= 18x^2(x^2 + 4)^2(2x^3 - 1)^2 + 4x(x^2 + 4)(2x^3 - 1)^3 \\ &= 2x(x^2 + 4)(2x^3 - 1)^2[9x(x^2 + 4) + 2(2x^3 - 1)] \\ &= \boxed{2x(x^2 + 4)(2x^3 - 1)(13x^3 + 36x - 2)}. \end{aligned}$$

30. Let $y = (x^2 - 2)^3(3x^4 + 1)^2$. Then

$$\begin{aligned} \frac{dy}{dx} &= \frac{d}{dx} [(x^2 - 2)^3(3x^4 + 1)^2] = (x^2 - 2)^3 \frac{d}{dx} (3x^4 + 1)^2 + (3x^4 + 1)^2 \frac{d}{dx} (x^2 - 2)^3 \\ &= (x^2 - 2)^3 \cdot 2(3x^4 + 1)^{2-1} \cdot \frac{d}{dx} (3x^4 + 1) + (3x^4 + 1)^2 \cdot 3(x^2 - 2)^{3-1} \cdot \frac{d}{dx} (x^2 - 2) \\ &= 2(x^2 - 2)^3(3x^4 + 1) \cdot 12x^3 + 3(x^2 - 2)^2(3x^4 + 1)^2 \cdot 2x \\ &= 24x^3(x^2 - 2)^3(3x^4 + 1) + 6x(x^2 - 2)^2(3x^4 + 1)^2 \\ &= 2x(x^2 - 2)^2(3x^4 + 1)[12x^2(x^2 - 2) + 3(3x^4 + 1)] \\ &= \boxed{2x(x^2 - 2)^2(3x^4 + 1)(21x^4 - 24x^2 + 3)}. \end{aligned}$$

31. Let $y = \left(\frac{\sin x}{x}\right)^2$. Then

$$\begin{aligned} \frac{dy}{dx} &= \frac{d}{dx} \left(\frac{\sin x}{x}\right)^2 = 2 \left(\frac{\sin x}{x}\right)^{2-1} \cdot \frac{d}{dx} \left(\frac{\sin x}{x}\right) \\ &= 2 \frac{\sin x}{x} \cdot \frac{x \cos x - \sin x}{x^2} = \boxed{\frac{2 \sin x (x \cos x - \sin x)}{x^3}}. \end{aligned}$$

32. Let $y = \left(\frac{x + \cos x}{x}\right)^5$. Then

$$\begin{aligned} \frac{dy}{dx} &= \frac{d}{dx} \left(\frac{x + \cos x}{x}\right)^5 = 5 \left(\frac{x + \cos x}{x}\right)^{5-1} \cdot \frac{d}{dx} \left(\frac{x + \cos x}{x}\right) \\ &= 5 \left(\frac{x + \cos x}{x}\right)^4 \cdot \frac{x(1 - \sin x) - (x + \cos x)}{x^2} = \boxed{-5 \left(\frac{x + \cos x}{x}\right)^4 \frac{x \sin x + \cos x}{x^2}}. \end{aligned}$$

33. Let $y = \sin(4x)$. Then $y' = \cos(4x) \cdot \frac{d}{dx}(4x) = \cos(4x) \cdot 4 = \boxed{4 \cos(4x)}$.

34. Let $y = \cos(5x)$. Then $y' = -\sin(5x) \cdot \frac{d}{dx}(5x) = -\sin(5x) \cdot 5 = \boxed{-5 \sin(5x)}$.

35. Let $y = 2 \sin(x^2 + 2x - 1)$. Then

$$y' = 2 \cos(x^2 + 2x - 1) \cdot \frac{d}{dx}(x^2 + 2x - 1) = \boxed{2 \cos(x^2 + 2x - 1) \cdot (2x + 2)}.$$

36. Let $y = \frac{1}{2} \cos(x^3 - 2x + 5)$. Then

$$\begin{aligned} y' &= -\frac{1}{2} \sin(x^3 - 2x + 5) \cdot \frac{d}{dx}(x^3 - 2x + 5) \\ &= -\frac{1}{2} \sin(x^3 - 2x + 5) \cdot (3x^2 - 2) = \boxed{-\frac{3x^2 - 2}{2} \sin(x^3 - 2x + 5)}. \end{aligned}$$

37. Let $y = \sin \frac{1}{x}$. Then

$$y' = \cos \frac{1}{x} \cdot \frac{d}{dx} \left(\frac{1}{x} \right) = \boxed{\cos \frac{1}{x} \cdot \left(-\frac{1}{x^2} \right)}.$$

38. Let $y = \sin \frac{3}{x}$. Then

$$y' = \cos \frac{3}{x} \cdot \frac{d}{dx} \left(\frac{3}{x} \right) = \boxed{\cos \frac{3}{x} \cdot \left(-\frac{3}{x^2} \right)}.$$

39. Let $y = \sec(4x)$. Then

$$y' = \sec(4x) \tan(4x) \cdot \frac{d}{dx}(4x) = \sec(4x) \tan(4x) \cdot 4 = \boxed{4 \sec(4x) \tan(4x)}.$$

40. Let $y = \cot(5x)$. Then

$$y' = -\csc^2(5x) \cdot \frac{d}{dx}(5x) = -\csc^2(5x) \cdot 5 = \boxed{-5 \csc^2(5x)}.$$

41. Let $y = e^{1/x}$. Then $y' = e^{1/x} \cdot \frac{d}{dx} \left(\frac{1}{x} \right) = \boxed{e^{1/x} \cdot \left(-\frac{1}{x^2} \right)}$.

42. Let $y = e^{1/x^2}$. Then $y' = e^{1/x^2} \cdot \frac{d}{dx} \left(\frac{1}{x^2} \right) = \boxed{e^{1/x^2} \cdot \left(-\frac{2}{x^3} \right)}$.

43. Let $y = \frac{1}{x^4 - 2x + 1} = (x^4 - 2x + 1)^{-1}$. Then

$$y' = -(x^4 - 2x + 1)^{-1-1} \cdot \frac{d}{dx}(x^4 - 2x + 1) = -(x^4 - 2x + 1)^{-2} \cdot (4x^3 - 2) = \boxed{-\frac{4x^3 - 2}{(x^4 - 2x + 1)^2}}.$$

44. Let $y = \frac{3}{x^5 + 2x^2 - 3} = 3(x^5 + 2x^2 - 3)^{-1}$. Then

$$y' = -3(x^5 + 2x^2 - 3)^{-1-1} \cdot \frac{d}{dx}(x^5 + 2x^2 - 3) = -3(x^5 + 2x^2 - 3)^{-2} \cdot (5x^4 + 4x) = \boxed{-\frac{15x^4 + 12x}{(x^5 + 2x^2 - 3)^2}}.$$

45. Let $y = \frac{100}{1 + 99e^{-x}} = 100(1 + 99e^{-x})^{-1}$. Then

$$\begin{aligned} y' &= -100(1 + 99e^{-x})^{-1-1} \cdot \frac{d}{dx}(1 + 99e^{-x}) = -100(1 + 99e^{-x})^{-2} \cdot 99e^{-x} \frac{d}{dx}(-x) \\ &= -9900e^{-x}(1 + 99e^{-x})^{-2} \cdot (-1) = \boxed{\frac{9900e^{-x}}{(1 + 99e^{-x})^2}}. \end{aligned}$$

46. Let $y = \frac{1}{1 + 2e^{-x}} = (1 + 2e^{-x})^{-1}$. Then

$$\begin{aligned} y' &= -(1 + 2e^{-x})^{-1-1} \cdot \frac{d}{dx}(1 + 2e^{-x}) = -(1 + 2e^{-x})^{-2} \cdot 2e^{-x} \cdot \frac{d}{dx}(-x) \\ &= -2e^{-x}(1 + 2e^{-x})^{-2} \cdot (-1) = \boxed{\frac{2e^{-x}}{(1 + 2e^{-x})^2}}. \end{aligned}$$

47. Let $y = 2^{\sin x}$. Then $y' = 2^{\sin x} \ln 2 \cdot \frac{d}{dx}(\sin x) = \boxed{2^{\sin x} \ln 2 \cdot \cos x}$.

48. Let $y = (\sqrt{3})^{\cos x}$. Then

$$y' = (\sqrt{3})^{\cos x} \ln \sqrt{3} \cdot \frac{d}{dx}(\cos x) = \boxed{-\frac{1}{2}(\sqrt{3})^{\cos x} \ln 3 \cdot \sin x}.$$

49. Let $y = 6^{\sec x}$. Then $y' = 6^{\sec x} \ln 6 \cdot \frac{d}{dx}(\sec x) = \boxed{6^{\sec x} \ln 6 \cdot \sec x \tan x}$.

50. Let $y = 3^{\tan x}$. Then $y' = 3^{\tan x} \ln 3 \cdot \frac{d}{dx}(\tan x) = \boxed{3^{\tan x} \ln 3 \cdot \sec^2 x}$.

51. Let $y = 5xe^{3x}$. Then

$$y' = 5x \frac{d}{dx}e^{3x} + e^{3x} \frac{d}{dx}(5x) = 5xe^{3x} \frac{d}{dx}(3x) + e^{3x}(5) = 5xe^{3x}(3) + 5e^{3x} = \boxed{15xe^{3x} + 5e^{3x}}.$$

52. Let $y = x^3e^{2x}$. Then

$$y' = x^3 \frac{d}{dx}e^{2x} + e^{2x} \frac{d}{dx}x^3 = x^3e^{2x} \frac{d}{dx}(2x) + e^{2x}(3x^2) = x^3e^{2x}(2) + 3x^2e^{2x} = \boxed{(2x^3 + 3x^2)e^{2x}}.$$

53. Let $y = x^2 \sin(4x)$. Then

$$\begin{aligned} y' &= x^2 \frac{d}{dx} \sin(4x) + \sin(4x) \frac{d}{dx}x^2 = x^2 \cos(4x) \frac{d}{dx}(4x) + \sin(4x) \cdot 2x \\ &= x^2 \cos(4x) \cdot 4 + 2x \sin(4x) = \boxed{4x^2 \cos(4x) + 2x \sin(4x)}. \end{aligned}$$

54. Let $y = x^2 \cos(4x)$. Then

$$\begin{aligned} y' &= x^2 \frac{d}{dx} \cos(4x) + \cos(4x) \frac{d}{dx}x^2 = -x^2 \sin(4x) \frac{d}{dx}(4x) + \cos(4x) \cdot 2x \\ &= -x^2 \sin(4x) \cdot 4 + 2x \cos(4x) = \boxed{-4x^2 \sin(4x) + 2x \cos(4x)}. \end{aligned}$$

55. Let $y = e^{-ax} \sin(bx)$. Then

$$\begin{aligned}\frac{dy}{dx} &= \frac{d}{dx}[e^{-ax} \sin(bx)] = e^{-ax} \frac{d}{dx} \sin(bx) + \sin(bx) \frac{d}{dx} e^{-ax} \\ &= e^{-ax} \cos(bx) \frac{d}{dx}(bx) + \sin(bx) e^{-ax} \frac{d}{dx}(-ax) = e^{-ax} \cos(bx) \cdot b + \sin(bx) e^{-ax} \cdot (-a) \\ &= \boxed{be^{-ax} \cos(bx) - ae^{-ax} \sin(bx)}.\end{aligned}$$

56. Let $y = e^{ax} \cos(-bx) = e^{ax} \cos(bx)$. Then

$$\begin{aligned}\frac{dy}{dx} &= \frac{d}{dx}[e^{ax} \cos(bx)] = e^{ax} \frac{d}{dx} \cos(bx) + \cos(bx) \frac{d}{dx} e^{ax} \\ &= e^{ax} \cdot (-\sin(bx)) \frac{d}{dx}(bx) + \cos(bx) e^{ax} \frac{d}{dx}(ax) = -e^{ax} \sin(bx) \cdot b + \cos(bx) e^{ax} \cdot a \\ &= \boxed{ae^{ax} \cos(bx) - be^{ax} \sin(bx)}.\end{aligned}$$

57. Let $y = \frac{e^{ax} - 1}{e^{ax} + 1}$. Then

$$\begin{aligned}\frac{dy}{dx} &= \frac{d}{dx} \left(\frac{e^{ax} - 1}{e^{ax} + 1} \right) = \frac{(e^{ax} + 1) \frac{d}{dx}(e^{ax} - 1) - (e^{ax} - 1) \frac{d}{dx}(e^{ax} + 1)}{(e^{ax} + 1)^2} \\ &= \frac{(e^{ax} + 1)e^{ax} \frac{d}{dx}(ax) - (e^{ax} - 1)e^{ax} \frac{d}{dx}(ax)}{(e^{ax} + 1)^2} = \frac{(e^{ax} + 1)e^{ax} \cdot a - (e^{ax} - 1)e^{ax} \cdot a}{(e^{ax} + 1)^2} \\ &= \frac{ae^{2ax} + ae^{ax} - ae^{2ax} + ae^{ax}}{(e^{ax} + 1)^2} = \boxed{\frac{2ae^{ax}}{(e^{ax} + 1)^2}}.\end{aligned}$$

58. Let $y = \frac{e^{-ax} + 1}{e^{bx} - 1}$. Then

$$\begin{aligned}\frac{dy}{dx} &= \frac{d}{dx} \left(\frac{e^{-ax} + 1}{e^{bx} - 1} \right) = \frac{(e^{bx} - 1) \frac{d}{dx}(e^{-ax} + 1) - (e^{-ax} + 1) \frac{d}{dx}(e^{bx} - 1)}{(e^{bx} - 1)^2} \\ &= \frac{(e^{bx} - 1)e^{-ax} \frac{d}{dx}(-ax) - (e^{-ax} + 1)e^{bx} \frac{d}{dx}(bx)}{(e^{bx} - 1)^2} = \frac{(e^{bx} - 1)e^{-ax} \cdot (-a) - (e^{-ax} + 1)e^{bx} \cdot b}{(e^{bx} - 1)^2} \\ &= \frac{-ae^{(b-a)x} + ae^{-ax} - be^{(b-a)x} - be^{bx}}{(e^{bx} - 1)^2} = \boxed{\frac{ae^{-ax} - (a+b)e^{(b-a)x} - be^{bx}}{(e^{bx} - 1)^2}}.\end{aligned}$$

59. Let $y = u^3$, $u = 3v^2 + 1$, and $v = \frac{4}{x^2}$. Then

$$y = u^3 = (3v^2 + 1)^3 = \left[3 \left(\frac{4}{x^2} \right)^2 + 1 \right]^3 = \boxed{\left(\frac{48}{x^4} + 1 \right)^3}.$$

Moreover,

$$\begin{aligned}\frac{dy}{du} &= \frac{d}{du} u^3 = 3u^2 = 3(3v^2 + 1)^2 = 3 \left[3 \left(\frac{4}{x^2} \right)^2 + 1 \right]^2 = 3 \left(\frac{48}{x^4} + 1 \right)^2 \\ \frac{du}{dv} &= \frac{d}{dv} (3v^2 + 1) = 6v = \frac{24}{x^2} \\ \frac{dv}{dx} &= \frac{d}{dx} \left(\frac{4}{x^2} \right) = -\frac{8}{x^3},\end{aligned}$$

so, by the Chain Rule,

$$\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dv} \cdot \frac{dv}{dx} = 3 \left(\frac{48}{x^4} + 1 \right)^2 \cdot \frac{24}{x^2} \cdot \left(-\frac{8}{x^3} \right) = \boxed{-\frac{576}{x^5} \left(\frac{48}{x^4} + 1 \right)^2}.$$

60. Let $y = 3u$, $u = 3v^2 - 4$, and $v = \frac{1}{x}$. Then

$$y = 3u = 3(3v^2 - 4) = 3 \left[3 \left(\frac{1}{x} \right)^2 - 4 \right] = \boxed{\frac{9}{x^2} - 12}.$$

Moreover,

$$\begin{aligned} \frac{dy}{du} &= \frac{d}{du} 3u = 3 \\ \frac{du}{dv} &= \frac{d}{dv} (3v^2 - 4) = 6v = \frac{6}{x} \\ \frac{dv}{dx} &= \frac{d}{dx} \left(\frac{1}{x} \right) = -\frac{1}{x^2}, \end{aligned}$$

so, by the Chain Rule,

$$\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dv} \cdot \frac{dv}{dx} = 3 \cdot \frac{6}{x} \cdot \left(-\frac{1}{x^2} \right) = \boxed{-\frac{18}{x^3}}.$$

61. Let $y = u^2 + 1$, $u = \frac{4}{v}$, and $v = x^2$. Then

$$y = u^2 + 1 = \frac{16}{v^2} + 1 = \frac{16}{(x^2)^2} = \boxed{\frac{16}{x^4} + 1}.$$

Moreover,

$$\begin{aligned} \frac{dy}{du} &= \frac{d}{du} (u^2 + 1) = 2u = \frac{8}{v} = \frac{8}{x^2} \\ \frac{du}{dv} &= \frac{d}{dv} \left(\frac{4}{v} \right) = -\frac{4}{v^2} = -\frac{4}{x^4} \\ \frac{dv}{dx} &= \frac{d}{dx} x^2 = 2x, \end{aligned}$$

so, by the Chain Rule,

$$\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dv} \cdot \frac{dv}{dx} = \frac{8}{x^2} \cdot \left(-\frac{4}{x^4} \right) \cdot 2x = \boxed{-\frac{64}{x^5}}.$$

62. Let $y = u^3 - 1$, $u = -\frac{2}{v}$, and $v = x^3$. Then

$$y = u^3 - 1 = -\frac{8}{v^3} - 1 = -\frac{8}{(x^3)^3} - 1 = \boxed{-\frac{8}{x^9} - 1}.$$

Moreover,

$$\begin{aligned} \frac{dy}{du} &= \frac{d}{du} (u^3 - 1) = 3u^2 = \frac{12}{v^2} = \frac{12}{x^6} \\ \frac{du}{dv} &= \frac{d}{dv} \left(-\frac{2}{v} \right) = \frac{2}{v^2} = \frac{2}{x^6} \\ \frac{dv}{dx} &= \frac{d}{dx} x^3 = 3x^2, \end{aligned}$$

so, by the Chain Rule,

$$\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dv} \cdot \frac{dv}{dx} = \frac{12}{x^6} \cdot \frac{2}{x^6} \cdot 3x^2 = \boxed{\frac{72}{x^{10}}}.$$

63. Let $y = e^{-2x} \cos(3x)$. Then

$$\begin{aligned} y' &= \frac{d}{dx}[e^{-2x} \cos(3x)] = e^{-2x} \frac{d}{dx} \cos(3x) + \cos(3x) \frac{d}{dx} e^{-2x} \\ &= e^{-2x} (-\sin(3x)) \frac{d}{dx} (3x) + \cos(3x) e^{-2x} \frac{d}{dx} (-2x) = -e^{-2x} \sin(3x) \cdot 3 + e^{-2x} \cos(3x) \cdot (-2) \\ &= \boxed{-3e^{-2x} \sin(3x) - 2e^{-2x} \cos(3x)}. \end{aligned}$$

64. Let $y = e^{\pi x} \tan(\pi x)$. Then

$$\begin{aligned} y' &= \frac{d}{dx}[e^{\pi x} \tan(\pi x)] = e^{\pi x} \frac{d}{dx} \tan(\pi x) + \tan(\pi x) \frac{d}{dx} e^{\pi x} \\ &= e^{\pi x} \sec^2(\pi x) \frac{d}{dx} (\pi x) + \tan(\pi x) \cdot e^{\pi x} \frac{d}{dx} (\pi x) = e^{\pi x} \sec^2(\pi x) \cdot \pi + e^{\pi x} \tan(\pi x) \cdot \pi \\ &= \boxed{\pi e^{\pi x} \sec^2(\pi x) + \pi e^{\pi x} \tan(\pi x)}. \end{aligned}$$

65. Let $y = \cos(e^{x^2})$. Then

$$y' = \frac{d}{dx} \cos(e^{x^2}) = -\sin(e^{x^2}) \frac{d}{dx} e^{x^2} = -\sin(e^{x^2}) e^{x^2} \frac{d}{dx} x^2 = -e^{x^2} \sin(e^{x^2}) \cdot 2x = \boxed{-2xe^{x^2} \sin(e^{x^2})}.$$

66. Let $y = \tan(e^{x^2})$. Then

$$y' = \frac{d}{dx} \tan(e^{x^2}) = \sec^2(e^{x^2}) \frac{d}{dx} e^{x^2} = \sec^2(e^{x^2}) e^{x^2} \frac{d}{dx} x^2 = e^{x^2} \sec^2(e^{x^2}) \cdot 2x = \boxed{2xe^{x^2} \sec^2(e^{x^2})}.$$

67. Let $y = e^{\cos(4x)}$. Then

$$\begin{aligned} y' &= \frac{d}{dx} e^{\cos(4x)} = e^{\cos(4x)} \frac{d}{dx} \cos(4x) = e^{\cos(4x)} (-\sin(4x)) \frac{d}{dx} (4x) \\ &= \boxed{e^{\cos(4x)} (-4 \sin(4x))}. \end{aligned}$$

68. Let $y = e^{\csc^2 x}$. Then

$$\begin{aligned} y' &= \frac{d}{dx} e^{\csc^2 x} = e^{\csc^2 x} \frac{d}{dx} \csc^2 x = e^{\csc^2 x} \cdot 2 \csc x \cdot \frac{d}{dx} \csc x \\ &= 2e^{\csc^2 x} \csc x \cdot (-\csc x \cot x) = \boxed{-2e^{\csc^2 x} \csc^2 x \cot x}. \end{aligned}$$

69. Let $y = 4 \sin^2(3x)$. Then

$$\begin{aligned} y' &= \frac{d}{dx} [4 \sin^2(3x)] = 8 \sin(3x) \frac{d}{dx} \sin(3x) = 8 \sin(3x) \cos(3x) \frac{d}{dx} (3x) = 8 \sin(3x) \cos(3x) \cdot 3 \\ &= \boxed{24 \sin(3x) \cos(3x)}. \end{aligned}$$

70. Let $y = 2 \cos^2(x^2)$. Then

$$\begin{aligned} y' &= \frac{d}{dx} 2 \cos^2(x^2) = 4 \cos(x^2) \frac{d}{dx} \cos(x^2) = 4 \cos(x^2) (-\sin(x^2)) \frac{d}{dx} x^2 = -4 \sin(x^2) \cos(x^2) \cdot 2x \\ &= \boxed{-8x \sin(x^2) \cos(x^2)}. \end{aligned}$$

71. Let $y = (x^3 + 1)^2$.

(a) Let $y = u^2$ and $u = x^3 + 1$. Then

$$\frac{dy}{du} = \frac{d}{du}u^2 = 2u = 2(x^3 + 1) \quad \text{and} \quad \frac{du}{dx} = \frac{d}{dx}(x^3 + 1) = 3x^2,$$

so, by the Chain Rule,

$$\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx} = 2(x^3 + 1) \cdot 3x^2 = \boxed{6x^2(x^3 + 1)}.$$

(b) By the Power Rule for Functions,

$$\frac{dy}{dx} = 2(x^3 + 1)^{2-1} \frac{d}{dx}(x^3 + 1) = 2(x^3 + 1)(3x^2) = \boxed{6x^2(x^3 + 1)}.$$

(c) Expanding first to obtain

$$y = (x^3 + 1)^2 = x^6 + 2x^3 + 1$$

and then differentiating yields

$$\frac{dy}{dx} = \boxed{6x^5 + 6x^2}.$$

(d) Because $6x^5 + 6x^2 = 6x^2(x^3 + 1)$, we see that the answers from parts (a) - (c) are identical.

72. Let $y = (x^2 - 2)^3$.

(a) Let $y = u^3$ and $u = x^2 - 2$. Then

$$\frac{dy}{du} = \frac{d}{du}u^3 = 3u^2 = 3(x^2 - 2)^2 \quad \text{and} \quad \frac{du}{dx} = \frac{d}{dx}(x^2 - 2) = 2x,$$

so, by the Chain Rule,

$$\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx} = 3(x^2 - 2)^2 \cdot 2x = \boxed{6x(x^2 - 2)^2}.$$

(b) By the Power Rule for Functions,

$$\frac{dy}{dx} = 3(x^2 - 2)^{3-1} \frac{d}{dx}(x^2 - 2) = 3(x^2 - 2)^2(2x) = \boxed{6x(x^2 - 2)^2}.$$

(c) Expanding first to obtain

$$y = (x^2 - 2)^3 = x^6 - 6x^4 + 12x^2 - 8$$

and then differentiating yields

$$\frac{dy}{dx} = \boxed{6x^5 - 24x^3 + 24x}.$$

(d) Because $6x^5 - 24x^3 + 24x = 6x(x^4 - 4x^2 + 4) = 6x(x^2 - 2)^2$, we see that the answers from parts (a) - (c) are identical.

73. Let $f(x) = (x^2 - 2x + 1)^5$.

(a) The slope of the line tangent to the graph of f at the point $(1, 0)$ is given by $f'(1)$. Now,

$$f'(x) = 5(x^2 - 2x + 1)^{5-1} \frac{d}{dx}(x^2 - 2x + 1) = 5(x^2 - 2x + 1)^4(2x - 2),$$

so

$$m_{\text{tan}} = f'(1) = 5(1 - 2 + 1)^4(2 - 2) = 0.$$

Therefore, the equation of the tangent line is

$$y - 0 = 0(x - 1) \quad \text{or} \quad \boxed{y = 0}.$$

- (b) The figure below displays the graph of f and its tangent line at the point $(1, 0)$. Here, the tangent line coincides with the x -axis.

74. Let $f(x) = (x^3 - x^2 + x - 1)^{10}$.

- (a) The slope of the line tangent to the graph of f at the point $(0, 1)$ is given by $f'(0)$. Now,

$$f'(x) = 10(x^3 - x^2 + x - 1)^{10-1} \frac{d}{dx}(x^3 - x^2 + x - 1) = 10(x^3 - x^2 + x - 1)^9(3x^2 - 2x + 1),$$

so

$$m_{\text{tan}} = f'(0) = 10(-1)^9(1) = -10.$$

Therefore, the equation of the tangent line is

$$y - 1 = -10(x - 0) \quad \text{or} \quad \boxed{y = -10x + 1}.$$

- (b) The figure below displays the graph of f (the solid curve) and its tangent line (the dashed curve) at the point $(0, 1)$.

75. Let $f(x) = \frac{x}{(x^2 - 1)^3}$.

- (a) The slope of the line tangent to the graph of f at the point $\left(2, \frac{2}{27}\right)$ is given by $f'(2)$. Now,

$$\begin{aligned} f'(x) &= \frac{(x^2 - 1)^3 \cdot 1 - x \cdot 3(x^2 - 1)^{3-1} \frac{d}{dx}(x^2 - 1)}{(x^2 - 1)^6} = \frac{(x^2 - 1)^3 - 6x^2(x^2 - 1)^2}{(x^2 - 1)^6} \\ &= \frac{(x^2 - 1)^2(x^2 - 1 - 6x^2)}{(x^2 - 1)^6} = -\frac{5x^2 + 1}{(x^2 - 1)^4}, \end{aligned}$$

so

$$m_{\text{tan}} = f'(2) = -\frac{5(2)^2 + 1}{(2^2 - 1)^4} = -\frac{7}{27}.$$

Therefore, the equation of the tangent line is

$$y - \frac{2}{27} = -\frac{7}{27}(x - 2) \quad \text{or} \quad \boxed{y = -\frac{7}{27}x + \frac{16}{27}}.$$

- (b) The figure below displays the graph of f (the solid curve) and its tangent line (the dashed curve) at the point $\left(2, \frac{2}{27}\right)$.

76. Let $f(x) = \frac{x^2}{(x^2 - 1)^2}$.

- (a) The slope of the line tangent to the graph of f at the point $\left(2, \frac{4}{9}\right)$ is given by $f'(2)$. Now,

$$\begin{aligned} f'(x) &= \frac{(x^2 - 1)^2 \cdot 2x - x^2 \cdot 2(x^2 - 1)^{2-1} \frac{d}{dx}(x^2 - 1)}{(x^2 - 1)^4} = \frac{2x(x^2 - 1)^2 - 4x^3(x^2 - 1)}{(x^2 - 1)^4} \\ &= \frac{2x(x^2 - 1)(x^2 - 1 - 2x^2)}{(x^2 - 1)^4} = -\frac{2x(x^2 + 1)}{(x^2 - 1)^3}, \end{aligned}$$

so

$$m_{\text{tan}} = f'(2) = -\frac{2(2)(2^2 + 1)}{(2^2 - 1)^3} = -\frac{20}{27}.$$

Therefore, the equation of the tangent line is

$$y - \frac{4}{9} = -\frac{20}{27}(x - 2) \quad \text{or} \quad \boxed{y = -\frac{20}{27}x + \frac{52}{27}}.$$

- (b) The figure below displays the graph of f (the solid curve) and its tangent line (the dashed curve) at the point $\left(2, \frac{4}{9}\right)$.

77. Let $f(x) = \sin(2x) + \cos \frac{x}{2}$.

- (a) The slope of the line tangent to the graph of f at the point $(0, 1)$ is given by $f'(0)$. Now,

$$f'(x) = \cos(2x) \frac{d}{dx}(2x) - \sin \frac{x}{2} \frac{d}{dx} \left(\frac{x}{2} \right) = 2 \cos(2x) - \frac{1}{2} \sin \frac{x}{2},$$

so

$$m_{\text{tan}} = f'(0) = 2 \cos 0 - \frac{1}{2} \sin 0 = 2.$$

Therefore, the equation of the tangent line is

$$y - 1 = 2(x - 0) \quad \text{or} \quad \boxed{y = 2x + 1}.$$

- (b) The figure below displays the graph of f (the solid curve) and its tangent line (the dashed curve) at the point $(0, 1)$.

78. Let $f(x) = \sin^2 x + \cos^3 x$.

- (a) The slope of the line tangent to the graph of f at the point $\left(\frac{\pi}{2}, 1\right)$ is given by $f'\left(\frac{\pi}{2}\right)$. Now,

$$f'(x) = 2 \sin x \frac{d}{dx} \sin x + 3 \cos^2 x \frac{d}{dx} \cos x = 2 \sin x \cos x - 3 \cos^2 x \sin x,$$

so

$$m_{\text{tan}} = f'\left(\frac{\pi}{2}\right) = 2 \sin \frac{\pi}{2} \cos \frac{\pi}{2} - 3 \cos^2 \frac{\pi}{2} \sin \frac{\pi}{2} = 0.$$

Therefore, the equation of the tangent line is

$$y - 1 = 0 \left(x - \frac{\pi}{2} \right) \quad \text{or} \quad \boxed{y = 1}.$$

- (b) The figure below displays the graph of f (the solid curve) and its tangent line (the dashed curve) at the point $\left(\frac{\pi}{2}, 1\right)$.

79. $\frac{d}{dx} \cos(x^5) = -\sin(x^5) \frac{d}{dx} x^5 = -5x^4 \sin(x^5)$. Therefore,

$$\begin{aligned} \frac{d^2}{dx^2} \cos(x^5) &= \frac{d}{dx} [-5x^4 \sin(x^5)] = -5x^4 \frac{d}{dx} \sin(x^5) + \sin(x^5) \frac{d}{dx} (-5x^4) \\ &= -5x^4 \cos(x^5) \frac{d}{dx} x^5 - 20x^3 \sin(x^5) = \boxed{-25x^8 \cos(x^5) - 20x^3 \sin(x^5)}. \end{aligned}$$

80. $\frac{d}{dx} \sin^3 x = 3 \sin^2 x \frac{d}{dx} \sin x = 3 \sin^2 x \cos x$. Therefore,

$$\begin{aligned} \frac{d^2}{dx^2} \sin^3 x &= \frac{d}{dx} [3 \sin^2 x \cos x] = 3 \sin^2 x \frac{d}{dx} \cos x + \cos x \frac{d}{dx} [3 \sin^2 x] \\ &= 3 \sin^2 x (-\sin x) + \cos x (6 \sin x) \frac{d}{dx} \sin x \\ &= -3 \sin^3 x + 6 \sin x \cos^2 x = -3 \sin^3 x + 6 \sin x (1 - \sin^2 x) = -9 \sin^3 x + 6 \sin x, \end{aligned}$$

and

$$\frac{d^3}{dx^3} \sin^3 x = \frac{d}{dx} (-9 \sin^3 x + 6 \sin x) = -27 \sin^2 x \frac{d}{dx} \sin x + 6 \cos x = \boxed{-27 \sin^2 x \cos x + 6 \cos x}.$$

81. Let $h = f \circ g$. Then

$$h'(1) = f'(g(1)) \cdot g'(1) = f'(2) \cdot (-2) = 6(-2) = \boxed{-12}.$$

82. Let $h = f \circ g$. Then

$$h'(1) = f'(g(1)) \cdot g'(1) = f'(3) \cdot 3 = 4(3) = \boxed{12}.$$

83. Let $h = g \circ f$. Then

$$h'(0) = g'(f(0)) \cdot f'(0) = g'(3) \cdot (-1) = 0(-1) = \boxed{0}.$$

84. Let $h = g \circ f$. Then

$$h'(2) = g'(f(2)) \cdot f'(2) = g'(-3) \cdot 4 = 3(4) = \boxed{12}.$$

85. Let $y = u^5 + u$ and $u = 4x^3 + x - 4$. Then

$$\begin{aligned} \frac{dy}{du} &= \frac{d}{du} (u^5 + u) = 5u^4 + 1 = 5(4x^3 + x - 4)^4 + 1, \\ \frac{du}{dx} &= \frac{d}{dx} (4x^3 + x - 4) = 12x^2 + 1, \end{aligned}$$

and

$$\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx} = [5(4x^3 + x - 4)^4 + 1] (12x^2 + 1).$$

Therefore, at $x = 1$, $\frac{dy}{dx}$ is equal to

$$[5(4 + 1 - 4)^4 + 1] (12 + 1) = 6(13) = \boxed{78}.$$

86. Let $y = e^u + 3u$ and $u = \cos x$. Then

$$\begin{aligned} \frac{dy}{du} &= \frac{d}{du} (e^u + 3u) = e^u + 3 = e^{\cos x} + 3, \\ \frac{du}{dx} &= \frac{d}{dx} \cos x = -\sin x, \end{aligned}$$

and

$$\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx} = -(e^{\cos x} + 3) \sin x.$$

Therefore, at $x = 0$, $\frac{dy}{dx}$ is equal to

$$-(e^{\cos 0} + 3) \sin 0 = -(e + 3)(0) = \boxed{0}.$$

Applications and Extensions

$$87. \frac{d}{dx} f(x^2 + 1) = f'(x^2 + 1) \cdot \frac{d}{dx} (x^2 + 1) = \boxed{f'(x^2 + 1) \cdot (2x)}.$$

$$88. \frac{d}{dx} f(1 - x^2) = f'(1 - x^2) \cdot \frac{d}{dx} (1 - x^2) = \boxed{f'(1 - x^2) \cdot (-2x)}.$$

89.

$$\begin{aligned} \frac{d}{dx} f\left(\frac{x+1}{x-1}\right) &= f'\left(\frac{x+1}{x-1}\right) \cdot \frac{d}{dx} \left(\frac{x+1}{x-1}\right) \\ &= f'\left(\frac{x+1}{x-1}\right) \cdot \frac{(x-1)(1) - (x+1)(1)}{(x-1)^2} = \boxed{f'\left(\frac{x+1}{x-1}\right) \cdot \left(-\frac{2}{(x-1)^2}\right)}. \end{aligned}$$

90.

$$\begin{aligned} \frac{d}{dx} f\left(\frac{1-x}{1+x}\right) &= f'\left(\frac{1-x}{1+x}\right) \cdot \frac{d}{dx} \left(\frac{1-x}{1+x}\right) \\ &= f'\left(\frac{1-x}{1+x}\right) \cdot \frac{(1+x)(-1) - (1-x)(1)}{(1+x)^2} = \boxed{f'\left(\frac{1-x}{1+x}\right) \cdot \left(-\frac{2}{(1+x)^2}\right)}. \end{aligned}$$

$$91. \frac{d}{dx} f(\sin x) = f'(\sin x) \cdot \frac{d}{dx} \sin x = \boxed{f'(\sin x) \cos x}.$$

$$92. \frac{d}{dx} f(\tan x) = f'(\tan x) \cdot \frac{d}{dx} \tan x = \boxed{f'(\tan x) \sec^2 x}.$$

$$93. \frac{d}{dx} f(\cos x) = f'(\cos x) \cdot \frac{d}{dx} \cos x = -f'(\cos x) \sin x. \text{ Therefore,}$$

$$\begin{aligned} \frac{d^2}{dx^2} f(\cos x) &= \frac{d}{dx} [-f'(\cos x) \sin x] = -f'(\cos x) \frac{d}{dx} (\sin x) + \sin x \frac{d}{dx} [-f'(\cos x)] \\ &= -f'(\cos x) \cos x - \sin x \cdot f''(\cos x) \frac{d}{dx} \cos x = -f'(\cos x) \cos x - \sin x \cdot f''(\cos x) \cdot (-\sin x) \\ &= \boxed{f''(\cos x) \sin^2 x - f'(\cos x) \cos x}. \end{aligned}$$

$$94. \frac{d}{dx} f(e^x) = f'(e^x) \cdot \frac{d}{dx} e^x = f'(e^x) e^x. \text{ Therefore,}$$

$$\begin{aligned} \frac{d^2}{dx^2} f(e^x) &= \frac{d}{dx} [f'(e^x) e^x] = f'(e^x) \frac{d}{dx} e^x + e^x \frac{d}{dx} f'(e^x) \\ &= f'(e^x) e^x + e^x \cdot f''(e^x) \frac{d}{dx} e^x = f'(e^x) e^x + e^x \cdot f''(e^x) e^x \\ &= \boxed{f'(e^x) e^x + f''(e^x) e^{2x}}. \end{aligned}$$

95. Let $s(t) = A \cos(\omega t + \phi)$, where A , ω , and ϕ are constants.

(a) Velocity is the derivative of position, so

$$v(t) = \frac{d}{dt}s(t) = -A \sin(\omega t + \phi) \frac{d}{dt}(\omega t + \phi) = \boxed{-A\omega \sin(\omega t + \phi)}.$$

(b) The velocity of the object will be zero when $\sin(\omega t + \phi) = 0$, which is when

$$\omega t + \phi = k\pi \quad \text{or} \quad \boxed{t = \frac{k\pi - \phi}{\omega}},$$

where k is any integer such that $k\pi - \phi \geq 0$.

(c) Acceleration is the derivative of velocity, so

$$a(t) = \frac{d}{dt}v(t) = -A\omega \cos(\omega t + \phi) \frac{d}{dt}(\omega t + \phi) = \boxed{-A\omega^2 \cos(\omega t + \phi)}.$$

(d) The acceleration of the object will be zero when $\cos(\omega t + \phi) = 0$, which is when

$$\omega t + \phi = \left(k - \frac{1}{2}\right)\pi \quad \text{or} \quad \boxed{t = \frac{\left(k - \frac{1}{2}\right)\pi - \phi}{\omega}},$$

where k is any integer such that $\left(k - \frac{1}{2}\right)\pi - \phi \geq 0$.

96. Let $s(t) = 8 - (2 - t)^3$.

(a) Velocity is the derivative of position, so

$$v(t) = \frac{d}{dt}s(t) = -3(2 - t)^{3-1} \frac{d}{dt}(2 - t) = \boxed{3(2 - t)^2}.$$

(b) Using the result from part (a),

$$\boxed{v(1) = 3(2 - 1)^2 = 3 \text{ meters/second}} \quad \text{and} \quad \boxed{v(2) = 3(2 - 2)^2 = 0 \text{ meters/second}}.$$

(c) Acceleration is the derivative of velocity, so

$$a(t) = \frac{d}{dt}v(t) = 6(2 - t)^{2-1} \frac{d}{dt}(2 - t) = \boxed{-6(2 - t)}.$$

(d) Using the result from part (c),

$$\boxed{a(1) = -6(2 - 1) = -6 \text{ meters/second}^2} \quad \text{and} \quad \boxed{a(2) = -6(2 - 2) = 0 \text{ meters/second}^2}.$$

(e) The bullet travels

$$s(2) = 8 - (2 - 2)^3 = 8 - 0 = \boxed{8 \text{ meters}}$$

into the bale of paper.

97. Let

$$s(t) = \frac{80}{3} \left[t + \frac{3}{\pi} \sin\left(\frac{\pi}{6}t\right) \right] = \frac{80}{3}t + \frac{80}{\pi} \sin\left(\frac{\pi}{6}t\right).$$

Then

$$v(t) = \frac{d}{dt}s(t) = \frac{80}{3} + \frac{80}{\pi} \cos\left(\frac{\pi}{6}t\right) \frac{d}{dt}\left(\frac{\pi}{6}t\right) = \frac{80}{3} + \frac{40}{3} \cos\left(\frac{\pi}{6}t\right)$$

and

$$a(t) = \frac{d}{dt}v(t) = -\frac{40}{3} \sin\left(\frac{\pi}{6}t\right) \frac{d}{dt}\left(\frac{\pi}{6}t\right) = \boxed{-\frac{20\pi}{9} \sin\left(\frac{\pi}{6}t\right)}.$$

98. Let $s(t) = \sin e^t$.

(a) The velocity of the object is

$$v(t) = \frac{d}{dt}s(t) = \cos e^t \frac{d}{dt}e^t = \boxed{e^t \cos e^t},$$

and the acceleration of the object is

$$a(t) = \frac{d}{dt}v(t) = e^t \frac{d}{dt} \cos e^t + \cos e^t \frac{d}{dt}e^t = e^t(-\sin e^t) \frac{d}{dt}e^t + e^t \cos e^t = \boxed{-e^{2t} \sin e^t + e^t \cos e^t}.$$

(b) For $t > 0$, the velocity of the object is first equal to zero when

$$e^t = \frac{\pi}{2} \quad \text{or} \quad \boxed{t = \ln \frac{\pi}{2} \text{ seconds}}.$$

(c) At the time found in part (b), the acceleration of the object is

$$-\left(\frac{\pi}{2}\right)^2 \sin \frac{\pi}{2} + \frac{\pi}{2} \cos \frac{\pi}{2} = \boxed{-\frac{\pi^2}{4} \text{ feet/second}^2}.$$

99. First,

$$\frac{dR}{dx} = \frac{d}{dx} \left(\frac{0.0048}{x^2} \right) = -\frac{0.0096}{x^3} = -\frac{0.0096}{(0.1991 + 0.000003T)^3}$$

and

$$\frac{dx}{dT} = \frac{d}{dT}(0.1991 + 0.000003T) = 0.000003,$$

so

$$\frac{dR}{dT} = \frac{dR}{dx} \cdot \frac{dx}{dT} = -\frac{2.88 \times 10^{-8}}{(0.1991 + 0.000003T)^3}.$$

Therefore, when $T = 320$ K,

$$\frac{dR}{dT} = -\frac{2.88 \times 10^{-8}}{(0.1991 + 0.000003(320))^3} = -\frac{2.88 \times 10^{-8}}{(0.20006)^3} \approx \boxed{-3.597 \times 10^{-6} \text{ ohms/K}}.$$

100. Let the position of the pendulum be given by $s(t) = 0.05 \sin(2t) + 3t$ for $0 \leq t \leq \pi$.

(a) Velocity is the derivative of position, so

$$v(t) = \frac{ds}{dt} = 0.05 \cos(2t) \frac{d}{dt}(2t) + 3 = 0.1 \cos(2t) + 3.$$

Therefore,

$$\begin{aligned} v(0) &= 0.1 \cos 0 + 3 = \boxed{3.1 \text{ meters/second}}; \\ v\left(\frac{\pi}{8}\right) &= 0.1 \cos \frac{\pi}{4} + 3 = \frac{\sqrt{2}}{20} + 3 \approx \boxed{3.07 \text{ meters/second}}; \\ v\left(\frac{\pi}{4}\right) &= 0.1 \cos \frac{\pi}{2} + 3 = \boxed{3 \text{ meters/second}}; \\ v\left(\frac{\pi}{2}\right) &= 0.1 \cos \pi + 3 = \boxed{2.9 \text{ meters/second}}; \\ v(\pi) &= 0.1 \cos(2\pi) + 3 = \boxed{3.1 \text{ meters/second}}. \end{aligned}$$

- (b) Acceleration is the derivative of velocity, so

$$a(t) = \frac{dv}{dt} = -0.1 \sin(2t) \frac{d}{dt}(2t) = -0.2 \sin(2t).$$

Therefore,

$$\begin{aligned} a(0) &= -0.2 \sin 0 = \boxed{0 \text{ meters/second}^2}; \\ a\left(\frac{\pi}{8}\right) &= -0.2 \sin \frac{\pi}{4} = -\frac{\sqrt{2}}{10} \approx \boxed{-0.14 \text{ meters/second}^2}; \\ a\left(\frac{\pi}{4}\right) &= -0.2 \sin \frac{\pi}{2} = \boxed{-0.2 \text{ meters/second}^2}; \\ a\left(\frac{\pi}{2}\right) &= -0.2 \sin \pi = \boxed{0 \text{ meters/second}^2}; \\ a(\pi) &= -0.2 \sin(2\pi) = \boxed{0 \text{ meters/second}^2}. \end{aligned}$$

- (c) The figure below displays the graphs of the position $s(t)$, the velocity $v(t)$, and the acceleration $a(t)$ of the pendulum.

101. Let $A(t) = 102 - 90e^{-0.21t}$.

- (a) $\lim_{t \rightarrow \infty} A(t) = 102 - 90 \lim_{t \rightarrow \infty} e^{-0.21t} = 102 - 90(0) = \boxed{102}$. In the long run, second-generation smart phones will penetrate 102% of the market.
- (b) The figure below displays the graph of A . The graph of A has a horizontal asymptote at $A = 102$, supporting the conclusion from part (a).

- (c) The rate of change of A with respect to time is

$$\frac{dA}{dt} = \frac{d}{dt}(102 - 90e^{-0.21t}) = -90e^{-0.21t} \frac{d}{dt}(-0.21t) = -90e^{-0.21t} \cdot (-0.21) = \boxed{18.9e^{-0.21t}}.$$

- (d) Using the result from part (c),

$$\boxed{A'(5) = 18.9e^{-0.21(5)} \approx 6.614\%/year} \quad \text{and} \quad \boxed{A'(10) = 18.9e^{-0.21(10)} \approx 2.314\%/year}.$$

Thus, in 2015, the market penetration of second-generation smart phones will be increasing at a rate of 6.614% per year, while in 2020, the market penetration of second-generation smart phones will be increasing at the slower rate of 2.314% per year.

- (e) The figure below displays the graph of A' . The graph of A' is decreasing from left to right, supporting the calculations at $t = 5$ and $t = 10$ in part (d).

102. Let $P(x) = 10^4 e^{-0.00012x}$. The rate of change of atmospheric pressure with respect to height is

$$P'(x) = 10^4 e^{-0.00012x} \frac{d}{dx}(-0.00012x) = 10^4 e^{-0.00012x} \cdot (-0.00012) = -1.2e^{-0.00012x}.$$

At $x = 500$ meters,

$$\boxed{P'(500) = -1.2e^{-0.00012(500)} \approx -1.13 \frac{\text{kilograms/square meter}}{\text{meter}}};$$

at $x = 750$ meters,

$$\boxed{P'(750) = -1.2e^{-0.00012(750)} \approx -1.10 \frac{\text{kilograms/square meter}}{\text{meter}}}.$$

103. Let $v(t) = \frac{mg}{k}(1 - e^{-kt/m})$.

- (a) Acceleration is the derivative of velocity, so

$$a(t) = \frac{d}{dt} \left[\frac{mg}{k} (1 - e^{-kt/m}) \right] = -\frac{mg}{k} e^{-kt/m} \frac{d}{dt} \left(-\frac{kt}{m} \right) = -\frac{mg}{k} e^{-kt/m} \cdot \left(-\frac{k}{m} \right) = \boxed{ge^{-kt/m}}.$$

- (b) $\lim_{t \rightarrow \infty} v(t) = \frac{mg}{k} - \frac{mg}{k} \lim_{t \rightarrow \infty} e^{-kt/m} = \frac{mg}{k} - \frac{mg}{k}(0) = \boxed{\frac{mg}{k}}$. Thus, in the long run, the speed of the hailstone stops increasing and approaches the constant value $\frac{mg}{k}$.

- (c) $\lim_{t \rightarrow \infty} a(t) = g \lim_{t \rightarrow \infty} e^{-kt/m} = g(0) = \boxed{0}$. Thus, in the long run, the acceleration of the hailstone approaches zero.

104. (a) Using the **ExpReg** function on a TI-84 Plus calculator, it is found that

$$E(t) = 9296(1.05)^t,$$

where t is the number of years since 1974.

- (b) The rate of change of E with respect to t is

$$\boxed{E'(t) = 9296(1.05)^t \ln 1.05}.$$

- (c) The rate of change at $t = 26$ is

$$E'(26) = 9296(1.05)^{26} \ln 1.05 \approx \boxed{1613 \text{ dollars per year}}.$$

- (d) The rate of change at $t = 31$ is

$$E'(31) = 9296(1.05)^{31} \ln 1.05 \approx \boxed{2058 \text{ dollars per year}}.$$

- (e) The rate of change at $t = 36$ is

$$E'(36) = 9296(1.05)^{36} \ln 1.05 \approx \boxed{2627 \text{ dollars per year}}.$$

- (f) From parts (c), (d), and (e), we can see that the rate of increase in mean earnings is growing over time, from roughly \$1600/year in 2000 to more than \$2000/year in 2005 and more than \$2600/year in 2010. An exponential function with a base larger than 1, as in this example, not only has a positive first derivative, it also has a positive second derivative, so the rate of increase of the function increases as the independent variable increases.

105. Suppose the velocity of the object $v = v(s)$ is expressed as a function of the position s . Then

$$a = \frac{dv}{dt} = \frac{dv}{ds} \cdot \frac{ds}{dt} = \frac{dv}{ds} \cdot v = v \frac{dv}{ds}.$$

106. Let

$$Q(t) = 21 + \frac{10 \sin\left(\frac{2\pi t}{7}\right)}{\sqrt{t} - \sqrt{20}},$$

where Q is Professor Miller's approval rating and $0 \leq t \leq 16$ is the number of weeks since the beginning of the semester.

- (a)

$$\begin{aligned} Q'(t) &= \frac{(\sqrt{t} - \sqrt{20}) \cdot 10 \cos\left(\frac{2\pi t}{7}\right) \cdot \frac{d}{dt}\left(\frac{2\pi t}{7}\right) - 10 \sin\left(\frac{2\pi t}{7}\right) \cdot \frac{1}{2\sqrt{t}}}{(\sqrt{t} - \sqrt{20})^2} \\ &= \boxed{\frac{\frac{20\pi}{7}(\sqrt{t} - \sqrt{20}) \cos\left(\frac{2\pi t}{7}\right) - \frac{5}{\sqrt{t}} \sin\left(\frac{2\pi t}{7}\right)}{(\sqrt{t} - \sqrt{20})^2}}. \end{aligned}$$

- (b) Using the result from part (a),

$$\begin{aligned} Q'(1) &= \frac{\frac{20\pi}{7}(1 - \sqrt{20}) \cos\left(\frac{2\pi}{7}\right) - 5 \sin\left(\frac{2\pi}{7}\right)}{(1 - \sqrt{20})^2} \approx \boxed{-1.94} \\ Q'(5) &= \frac{\frac{20\pi}{7}(\sqrt{5} - \sqrt{20}) \cos\left(\frac{10\pi}{7}\right) - \sqrt{5} \sin\left(\frac{10\pi}{7}\right)}{(\sqrt{5} - \sqrt{20})^2} \approx \boxed{1.33} \\ Q'(10) &= \frac{\frac{20\pi}{7}(\sqrt{10} - \sqrt{20}) \cos\left(\frac{20\pi}{7}\right) - \frac{\sqrt{10}}{2} \sin\left(\frac{20\pi}{7}\right)}{(\sqrt{10} - \sqrt{20})^2} \approx \boxed{5.77}. \end{aligned}$$

- (c) The results in part (b) indicate: at the end of the first week of the semester, Professor Miller's approval rating was dropping at nearly 2 approval points per week; by the end of the fifth week of the semester, Professor Miller's approval rating was increasing at roughly one-and-one-third point per week; at the end of the tenth week of the semester, Professor Miller's approval rating was increasing at nearly 6 points per week.
- (d) The graphs of $Q(t)$ and $Q'(t)$ are shown below left and below right, respectively.

- (e) Professor Miller's approval rating oscillates with increasing amplitude throughout the semester. Peaks in approval rating occur at the start of the semester, during the sixth week of the semester and during the thirteenth week of the semester, with the highest approval occurring during the thirteenth week. Lows in student approval occur at the end of the second week, at the end of the ninth week and at the end of the semester, with the lowest approval occurring at the end of the semester.

The rate of change of Professor Miller's approval rating also oscillates with increasing amplitude throughout the semester. The approval rating is increasing most rapidly near the end of the fourth week and near the end of the eleventh week of the semester; the approval rating is decreasing most rapidly during the first week, the eighth week and the fifteenth week of the semester.

107. Let $\theta(t) = \frac{\pi}{3} \cos\left(\frac{1}{2}\sqrt{\frac{2k}{5}}t\right)$.

- (a) The angular velocity is given by

$$\begin{aligned}\omega(t) &= \frac{d\theta}{dt} = -\frac{\pi}{3} \sin\left(\frac{1}{2}\sqrt{\frac{2k}{5}}t\right) \cdot \frac{d}{dt}\left(\frac{1}{2}\sqrt{\frac{2k}{5}}t\right) \\ &= -\frac{\pi}{3} \left(\frac{1}{2}\sqrt{\frac{2k}{5}}\right) \sin\left(\frac{1}{2}\sqrt{\frac{2k}{5}}t\right) = \boxed{-\frac{\pi}{6}\sqrt{\frac{2k}{5}} \sin\left(\frac{1}{2}\sqrt{\frac{2k}{5}}t\right)}.\end{aligned}$$

- (b) The angular velocity at $t = 3$ is

$$\boxed{\omega(3) = -\frac{\pi}{6}\sqrt{\frac{2k}{5}} \sin\left(\frac{3}{2}\sqrt{\frac{2k}{5}}\right)}.$$

108. (a) Let $l(t) = 2 + \cos(2\pi t)$. Then

$$\begin{aligned} l(0) &= 2 + \cos 0 = 2 + 1 = \boxed{3 \text{ meters}}; \\ l\left(\frac{1}{2}\right) &= 2 + \cos \pi = 2 - 1 = \boxed{1 \text{ meter}}; \\ l(1) &= 2 + \cos(2\pi) = 2 + 1 = \boxed{3 \text{ meters}}; \\ l\left(\frac{3}{2}\right) &= 2 + \cos(3\pi) = 2 - 1 = \boxed{1 \text{ meter}}; \\ l\left(\frac{5}{8}\right) &= 2 + \cos\left(\frac{5\pi}{4}\right) = 2 - \frac{\sqrt{2}}{2} \approx \boxed{1.3 \text{ meters}}. \end{aligned}$$

- (b) Velocity is the derivative of length, so

$$v(t) = l'(t) = -\sin(2\pi t) \frac{d}{dt}(2\pi t) = -2\pi \sin(2\pi t).$$

Then

$$v\left(\frac{1}{4}\right) = -2\pi \sin\left(\frac{\pi}{2}\right) = -2\pi \approx \boxed{-6.3 \text{ meters/second}}.$$

- (c) Acceleration is the derivative of velocity, so

$$a(t) = v'(t) = -2\pi \cos(2\pi t) \frac{d}{dt}(2\pi t) = -4\pi^2 \cos(2\pi t).$$

Then

$$a\left(\frac{1}{4}\right) = -4\pi^2 \cos\left(\frac{\pi}{2}\right) = \boxed{0 \text{ meters/second}^2}.$$

109. Let $F(t) = f(t^2 - 1)$ and $f(x) = \sin x$. Then

$$F'(t) = f'(t^2 - 1) \frac{d}{dt}(t^2 - 1) = 2tf'(t^2 - 1), \quad \text{so} \quad F'(1) = 2f'(0).$$

Now,

$$f'(x) = \cos x, \quad \text{so} \quad f'(0) = \cos 0 = 1.$$

Finally, $F'(1) = 2(1) = \boxed{2}$.

110. Let $f(x) = e^{-x}$, and suppose the point in question is (t, e^{-t}) . The slope of the line tangent to the graph of f at $x = t$ is $f'(t) = -e^{-t}$, so the slope of the normal line is

$$-\frac{1}{-e^{-t}} = e^t.$$

The equation of the normal line is then

$$y - e^{-t} = e^t(x - t).$$

In order for this line to pass through the origin, t must satisfy the equation

$$0 - e^{-t} = e^t(0 - t) \quad \text{or} \quad 1 = te^{2t}.$$

Using the computer algebra system *Mathematica*, the approximate solution to this equation is found to be $t \approx 0.426303$. The point on the graph of $y = e^{-x}$, where the normal line to the graph passes through the origin, is then

$$\boxed{(0.426303, e^{-0.426303}) \approx (0.426303, 0.652918)}.$$

111. $\frac{d}{dx} \cos x = \frac{d}{dx} \sin \left(\frac{\pi}{2} - x \right) = \cos \left(\frac{\pi}{2} - x \right) \frac{d}{dx} \left(\frac{\pi}{2} - x \right) = \sin x \cdot (-1) = -\sin x.$

112. Let $y = e^{2x}$. Then $y' = e^{2x} \cdot \frac{d}{dx}(2x) = 2e^{2x}$ and $y'' = 2e^{2x} \cdot \frac{d}{dx}(2x) = 4e^{2x}$. Therefore,

$$y'' - 4y = 4e^{2x} - 4e^{2x} = 0.$$

113. Let $y = e^{-2x}$. Then $y' = e^{-2x} \cdot \frac{d}{dx}(-2x) = -2e^{-2x}$ and $y'' = -2e^{-2x} \cdot \frac{d}{dx}(-2x) = 4e^{-2x}$. Therefore,

$$y'' - 4y = 4e^{-2x} - 4e^{-2x} = 0.$$

114. Let $y = Ae^{2x} + Be^{-2x}$. Then

$$\begin{aligned} y' &= Ae^{2x} \cdot \frac{d}{dx}(2x) + Be^{-2x} \cdot \frac{d}{dx}(-2x) = 2Ae^{2x} - 2Be^{-2x}, \\ y'' &= 2Ae^{2x} \cdot \frac{d}{dx}(2x) - 2Be^{-2x} \cdot \frac{d}{dx}(-2x) = 4Ae^{2x} + 4Be^{-2x}, \end{aligned}$$

and

$$y'' - 4y = 4Ae^{2x} + 4Be^{-2x} - 4(Ae^{2x} + Be^{-2x}) = 0.$$

115. Let $y = Ae^{ax} + Be^{-ax}$. Then

$$\begin{aligned} y' &= Ae^{ax} \cdot \frac{d}{dx}(ax) + Be^{-ax} \cdot \frac{d}{dx}(-ax) = aAe^{ax} - aBe^{-ax}, \\ y'' &= aAe^{ax} \cdot \frac{d}{dx}(ax) - aBe^{-ax} \cdot \frac{d}{dx}(-ax) = a^2Ae^{ax} + a^2Be^{-ax}, \end{aligned}$$

and

$$y'' - a^2y = a^2Ae^{ax} + a^2Be^{-ax} - a^2(Ae^{ax} + Be^{-ax}) = 0.$$

116. Let $y = Ae^{2x} + Be^{3x}$. Then

$$\begin{aligned} y' &= Ae^{2x} \cdot \frac{d}{dx}(2x) + Be^{3x} \cdot \frac{d}{dx}(3x) = 2Ae^{2x} + 3Be^{3x}, \\ y'' &= 2Ae^{2x} \cdot \frac{d}{dx}(2x) + 3Be^{3x} \cdot \frac{d}{dx}(3x) = 4Ae^{2x} + 9Be^{3x}, \end{aligned}$$

and

$$\begin{aligned} y'' - 5y' + 6y &= 4Ae^{2x} + 9Be^{3x} - 5(2Ae^{2x} + 3Be^{3x}) + 6(Ae^{2x} + Be^{3x}) \\ &= (4A - 10A + 6A)e^{2x} + (9B - 15B + 6B)e^{3x} = 0. \end{aligned}$$

117. Let $y = Ae^{-2x} + Be^{-x}$. Then

$$\begin{aligned} y' &= Ae^{-2x} \cdot \frac{d}{dx}(-2x) + Be^{-x} \cdot \frac{d}{dx}(-x) = -2Ae^{-2x} - Be^{-x}, \\ y'' &= -2Ae^{-2x} \cdot \frac{d}{dx}(-2x) - Be^{-x} \cdot \frac{d}{dx}(-x) = 4Ae^{-2x} + Be^{-x}, \end{aligned}$$

and

$$\begin{aligned} y'' + 3y' + 2y &= 4Ae^{-2x} + Be^{-x} + 3(-2Ae^{-2x} - Be^{-x}) + 2(Ae^{-2x} + Be^{-x}) \\ &= (4A - 6A + 2A)e^{-2x} + (B - 3B + 2B)e^{-x} = 0. \end{aligned}$$

118. Let $y = A \sin(\omega t) + B \cos(\omega t)$. Then

$$\begin{aligned} y' &= A \cos(\omega t) \cdot \frac{d}{dt}(\omega t) - B \sin(\omega t) \frac{d}{dt}(\omega t) = A\omega \cos(\omega t) - B\omega \sin(\omega t), \\ y'' &= -A\omega \sin(\omega t) \frac{d}{dt}(\omega t) - B\omega \cos(\omega t) \frac{d}{dt}(\omega t) = -A\omega^2 \sin(\omega t) - B\omega^2 \cos(\omega t), \end{aligned}$$

and

$$y'' + \omega^2 y = -A\omega^2 \sin(\omega t) - B\omega^2 \cos(\omega t) + \omega^2(A \sin(\omega t) + B \cos(\omega t)) = 0.$$

119. $\frac{d}{dx}f(h(x)) = f'(h(x)) \cdot h'(x) = g(h(x)) \cdot 2x = 2xg(x^2)$.

120. Let $f(x) = (2x + 3)^n$. Then

$$\begin{aligned} \frac{df}{dx} &= n(2x + 3)^{n-1} \frac{d}{dx}(2x + 3) = 2n(2x + 3)^{n-1} \\ \frac{d^2f}{dx^2} &= 2n(n-1)(2x + 3)^{n-2} \frac{d}{dx}(2x + 3) = 2^2n(n-1)(2x + 3)^{n-2} \\ \frac{d^3f}{dx^3} &= 2^2n(n-1)(n-2)(2x + 3)^{n-3} \frac{d}{dx}(2x + 3) = 2^3n(n-1)(n-2)(2x + 3)^{n-3}, \end{aligned}$$

and so on. Based on this pattern, the n th derivative would be

$$\frac{d^n f}{dx^n} = 2^n n(n-1)(n-2) \cdots (2)(1)(2x + 3)^{n-n} = \boxed{2^n n!}.$$

121. (a) Let $y = e^{ax}$. Then

$$\begin{aligned} \frac{dy}{dx} &= e^{ax} \frac{d}{dx}(ax) = ae^{ax} \\ \frac{d^2y}{dx^2} &= ae^{ax} \frac{d}{dx}(ax) = a^2e^{ax} \\ \frac{d^3y}{dx^3} &= a^2e^{ax} \frac{d}{dx}(ax) = a^3e^{ax}, \end{aligned}$$

and so on. Each derivative results in multiplication by an additional factor of a , so the n th derivative of y would be $\boxed{a^n e^{ax}}$.

(b) Let $y = e^{-ax}$. Then

$$\begin{aligned} \frac{dy}{dx} &= e^{-ax} \frac{d}{dx}(-ax) = -ae^{-ax} \\ \frac{d^2y}{dx^2} &= -ae^{-ax} \frac{d}{dx}(-ax) = a^2e^{-ax} \\ \frac{d^3y}{dx^3} &= a^2e^{-ax} \frac{d}{dx}(-ax) = -a^3e^{-ax}, \end{aligned}$$

and so on. Each derivative results in multiplication by an additional factor of $-a$, so the n th derivative of y would be $\boxed{(-a)^n e^{-ax} = (-1)^n a^n e^{-ax}}$.

122. Let $f(x) = \sin(ax)$. Then

$$\begin{aligned} \frac{df}{dx} &= \cos(ax) \cdot \frac{d}{dx}(ax) = a \cos(ax); \\ \frac{d^2f}{dx^2} &= \frac{d}{dx}[a \cos(ax)] = -a \sin(ax) \cdot \frac{d}{dx}(ax) = -a^2 \sin(ax) \\ \frac{d^3f}{dx^3} &= \frac{d}{dx}[-a^2 \sin(ax)] = -a^2 \cos(ax) \cdot \frac{d}{dx}(ax) = -a^3 \cos(ax) \\ \frac{d^4f}{dx^4} &= \frac{d}{dx}[-a^3 \cos(ax)] = a^3 \sin(ax) \frac{d}{dx}(ax) = a^4 \sin(ax), \end{aligned}$$

and so on. At this point, the two elements of the pattern in these derivatives can be identified. First, each derivative introduces multiplication by a factor of a . Second, the trigonometric function in the derivatives cycles through $\sin(ax)$, $\cos(ax)$, $-\sin(ax)$, and $-\cos(ax)$, in that order, with each set of four derivatives.

- (a) Because the trigonometric function in the derivatives goes in a cycle of four, the tenth derivative will be like the second derivative in that it will contain the function $-\sin(ax)$. The tenth derivative will also include ten factors of a , so

$$\frac{d^{10}}{dx^{10}} \sin(ax) = \boxed{-a^{10} \sin(ax)}.$$

- (b) Because the trigonometric function in the derivatives goes in a cycle of four, the twenty-fifth derivative will be like the first derivative in that it will contain the function $\cos(ax)$. The twenty-fifth derivative will also contain 25 factors of a , so

$$\frac{d^{25}}{dx^{25}} \sin(ax) = \boxed{a^{25} \cos(ax)}.$$

- (c) The n th derivative of $f(x) = \sin(ax)$ will be

$$\begin{cases} a^n \sin(ax), & \text{if } n = 4k, k = 0, 1, 2, 3, \dots \\ a^n \cos(ax), & \text{if } n = 4k + 1, k = 0, 1, 2, 3, \dots \\ -a^n \sin(ax), & \text{if } n = 4k + 2, k = 0, 1, 2, 3, \dots \\ -a^n \cos(ax), & \text{if } n = 4k + 3, k = 0, 1, 2, 3, \dots \end{cases}$$

123. Let $f(x) = \cos(ax)$. Then

$$\begin{aligned} \frac{df}{dx} &= -\sin(ax) \cdot \frac{d}{dx}(ax) = -a \sin(ax); \\ \frac{d^2 f}{dx^2} &= \frac{d}{dx}[-a \sin(ax)] = -a \cos(ax) \cdot \frac{d}{dx}(ax) = -a^2 \cos(ax) \\ \frac{d^3 f}{dx^3} &= \frac{d}{dx}[-a^2 \cos(ax)] = a^2 \sin(ax) \cdot \frac{d}{dx}(ax) = a^3 \sin(ax) \\ \frac{d^4 f}{dx^4} &= \frac{d}{dx}[a^3 \sin(ax)] = a^3 \cos(ax) \cdot \frac{d}{dx}(ax) = a^4 \cos(ax), \end{aligned}$$

and so on. At this point, the two elements of the pattern in these derivatives can be identified. First, each derivative introduces multiplication by a factor of a . Second, the trigonometric function in the derivatives cycles through $\cos(ax)$, $-\sin(ax)$, $-\cos(ax)$, and $\sin(ax)$, in that order, with each set of four derivatives.

- (a) Because the trigonometric function in the derivatives goes in a cycle of four, the eleventh derivative will be like the third derivative in that it will contain the function $\sin(ax)$. The eleventh derivative will also include eleven factors of a , so

$$\frac{d^{11}}{dx^{11}} \cos(ax) = \boxed{a^{11} \sin(ax)}.$$

- (b) Because the trigonometric function in the derivatives goes in a cycle of four, the twelfth derivative will be like the original function in that it will contain the function $\cos(ax)$. The twelfth derivative will also contain 12 factors of a , so

$$\frac{d^{12}}{dx^{12}} \cos(ax) = \boxed{a^{12} \cos(ax)}.$$

(c) The n th derivative of $f(x) = \cos(ax)$ will be

$$\begin{cases} a^n \cos(ax), & \text{if } n = 4k, k = 0, 1, 2, 3, \dots \\ -a^n \sin(ax), & \text{if } n = 4k + 1, k = 0, 1, 2, 3, \dots \\ -a^n \cos(ax), & \text{if } n = 4k + 2, k = 0, 1, 2, 3, \dots \\ a^n \sin(ax), & \text{if } n = 4k + 3, k = 0, 1, 2, 3, \dots \end{cases}$$

124. Let $y = e^{-at}[A \sin(\omega t) + B \cos(\omega t)]$, where A , B , a , and ω are constants. Then

$$\begin{aligned} y' &= e^{-at} \frac{d}{dt}[A \sin(\omega t) + B \cos(\omega t)] + [A \sin(\omega t) + B \cos(\omega t)] \frac{d}{dt}e^{-at} \\ &= e^{-at}[A\omega \cos(\omega t) - B\omega \sin(\omega t)] + [A \sin(\omega t) + B \cos(\omega t)] \cdot (-ae^{-at}) \\ &= \boxed{e^{-at}[(A\omega - Ba) \cos(\omega t) - (B\omega + Aa) \sin(\omega t)]}, \end{aligned}$$

and

$$\begin{aligned} y'' &= e^{-at} \frac{d}{dt}[(A\omega - Ba) \cos(\omega t) - (B\omega + Aa) \sin(\omega t)] + \\ &\quad [(A\omega - Ba) \cos(\omega t) - (B\omega + Aa) \sin(\omega t)] \frac{d}{dt}e^{-at} \\ &= e^{-at}[-(A\omega - Ba)\omega \sin(\omega t) - (B\omega + Aa)\omega \cos(\omega t)] + \\ &\quad [(A\omega - Ba) \cos(\omega t) - (B\omega + Aa) \sin(\omega t)] \cdot (-ae^{-at}) \\ &= \boxed{e^{-at}[(-A\omega^2 + 2Baw + Aa^2) \sin(\omega t) + (-B\omega^2 - 2Aa\omega + Ba^2) \cos(\omega t)]}. \end{aligned}$$

125. Consider the limit that appears in the definition of the derivative; that is,

$$\lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h}.$$

Using the property that $f(u+v) = f(u)f(v)$ for all choices of u and v , it follows that

$$\lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = \lim_{h \rightarrow 0} \frac{f(x) \cdot f(h) - f(x)}{h} = \lim_{h \rightarrow 0} \frac{f(x)[f(h) - 1]}{h}.$$

Next, given that $f(x) = 1 + xg(x)$,

$$\lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = \lim_{h \rightarrow 0} \frac{f(x)[(1 + hg(h)) - 1]}{h} = \lim_{h \rightarrow 0} \frac{hf(x)g(h)}{h} = f(x) \lim_{h \rightarrow 0} g(h).$$

We were able to pull the factor $f(x)$ outside of the limit because $f(x)$ is a constant with respect to h , the variable associated with the limit. Finally, because $\lim_{x \rightarrow 0} g(x) = 1$,

$$\lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = f(x) \cdot 1 = f(x).$$

Because

$$\lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h}$$

exists and is equal to $f(x)$, it follows that f is differentiable and $f'(x) = f(x)$.

Challenge Problems

126. Let $f(x) = \frac{1}{3x-4} = (3x-4)^{-1}$. Then

$$\begin{aligned}\frac{df}{dx} &= -1(3x-4)^{-1-1} \frac{d}{dx}(3x-4) = -3(3x-4)^{-2} = (-3)^1 \cdot 1! \cdot (3x-4)^{-2} \\ \frac{d^2f}{dx^2} &= (-3)(-2)(1)(3x-4)^{-2-1} \frac{d}{dx}(3x-4) = -(3)^2 \cdot 2! \cdot (3x-4)^{-3} \\ \frac{d^3f}{dx^3} &= (-3)^2(2!)(-3)(3x-4)^{-3-1} \frac{d}{dx}(3x-4) = (-3)^3 \cdot 3! \cdot (3x-4)^{-4},\end{aligned}$$

and so on. Following this pattern, the n th derivative is

$$\boxed{\frac{d^n f}{dx^n} = (-3)^n \cdot n! \cdot (3x-4)^{-n-1}}.$$

127. Repeatedly applying the Chain Rule yields

$$\begin{aligned}\frac{d}{dx} f_1(f_2(f_3(\cdots(f_n(x))\cdots))) \\ &= f'_1(f_2(f_3(\cdots(f_n(x))\cdots))) \frac{d}{dx} f_2(f_3(\cdots(f_n(x))\cdots)) \\ &= f'_1(f_2(f_3(\cdots(f_n(x))\cdots))) f'_2(f_3(\cdots(f_n(x))\cdots)) \frac{d}{dx} f_3(f_4(\cdots(f_n(x))\cdots)) \\ &= f'_1(f_2(f_3(\cdots(f_n(x))\cdots))) f'_2(f_3(\cdots(f_n(x))\cdots)) f'_3(f_4(\cdots(f_n(x))\cdots)) \frac{d}{dx} f_4(f_5(\cdots(f_n(x))\cdots)) \\ &\vdots \\ &= \boxed{f'_1(f_2(f_3(\cdots(f_n(x))\cdots))) f'_2(f_3(\cdots(f_n(x))\cdots)) f'_3(f_4(\cdots(f_n(x))\cdots)) \cdots f'_n(x)}.\end{aligned}$$

128. Consider the limit

$$\lim_{h \rightarrow 0} \frac{f(0+h) - f(0)}{h} = \lim_{h \rightarrow 0} \frac{h^2 \sin \frac{1}{h} - 0}{h} = \lim_{h \rightarrow 0} \left[h \sin \frac{1}{h} \right].$$

Now,

$$\left| \sin \frac{1}{h} \right| \leq 1, \quad \text{so} \quad |h| \left| \sin \frac{1}{h} \right| = \left| h \sin \frac{1}{h} \right| \leq |h| \quad \text{and} \quad -|h| \leq h \sin \frac{1}{h} \leq |h|$$

for all $h \neq 0$. Because

$$\lim_{h \rightarrow 0} (-|h|) = 0 \quad \text{and} \quad \lim_{h \rightarrow 0} |h| = 0,$$

it follows from the Squeeze Theorem that

$$\lim_{h \rightarrow 0} \left[h \sin \frac{1}{h} \right] = 0.$$

Therefore,

$$\lim_{h \rightarrow 0} \frac{f(0+h) - f(0)}{h} = 0.$$

Because

$$\lim_{h \rightarrow 0} \frac{f(0+h) - f(0)}{h}$$

exists and is equal to 0, f is differentiable at $x = 0$ with $f'(0) = 0$. For $x \neq 0$,

$$f'(x) = x^2 \frac{d}{dx} \sin \frac{1}{x} + \sin \frac{1}{x} \frac{d}{dx} x^2 = x^2 \cos \frac{1}{x} \cdot \frac{d}{dx} \left(\frac{1}{x} \right) + 2x \sin \frac{1}{x} = -\cos \frac{1}{x} + 2x \sin \frac{1}{x}.$$

As x approaches 0, the second term in this derivative tends to 0 but the first term just oscillates between -1 and 1 . Therefore, $\lim_{x \rightarrow 0} f'(x)$ does not exist, so that $f'(x)$ is not continuous at 0.

129. For $x \neq 0$, f is the composition of the exponential function e^x , which is differentiable for all x , and the rational function $-1/x^2$, which is differentiable for $x \neq 0$. Therefore, f is differentiable for $x \neq 0$, and

$$f'(x) = \frac{d}{dx} e^{-1/x^2} = e^{-1/x^2} \frac{d}{dx} \left(-\frac{1}{x^2} \right) = \frac{2}{x^3} e^{-1/x^2}.$$

At $x = 0$, consider the limit

$$\lim_{h \rightarrow 0} \frac{f(0+h) - f(0)}{h} = \frac{e^{-1/h^2} - 0}{h} = \lim_{h \rightarrow 0} \frac{e^{-1/h^2}}{h}.$$

To proceed further, consider the function $g(x) = e^x - x$. Note that $g(0) = e^0 - 0 = 1 > 0$. Moreover, $g'(x) = e^x - 1 > 0$ for $x > 0$. Because the rate of change of g is positive for $x > 0$, it follows that $g(x) > g(0)$ for $x > 0$. Thus, for $x > 0$, $e^x - x > 0$, or $e^x > x$. Now, for $x \neq 0$, $1/x^2 > 0$, so

$$e^{1/x^2} > \frac{1}{x^2} \quad \text{or} \quad e^{-1/x^2} < x^2$$

for $x \neq 0$. As $e^{-1/x^2} > 0$ for $x \neq 0$, it follows that

$$\left| e^{-1/x^2} \right| < |x|^2, \quad \text{so that} \quad \left| \frac{e^{-1/x^2}}{x} \right| < |x|,$$

or

$$-|x| < \frac{e^{-1/x^2}}{x} < |x|.$$

Now,

$$\lim_{x \rightarrow 0} (-|x|) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} |x| = 0,$$

so, by the Squeeze Theorem,

$$\lim_{x \rightarrow 0} \frac{e^{-1/x^2}}{x} = 0.$$

It follows that

$$\lim_{h \rightarrow 0} \frac{f(0+h) - f(0)}{h} = 0,$$

which implies that $f'(0)$ exists and is equal to 0. Therefore, f is differentiable on $(-\infty, \infty)$.

130. (a) Yes, the function $f(x) = x^2$ is differentiable at all real numbers x .
- (b) No, the function $g(x) = |x-1|$ is not differentiable at all real numbers x . Because of the presence of the absolute value function, g' does not exist at $x = 1$.
- (c) Because the Chain Rule calculates the derivative of the composition $(f \circ g)(x)$ as $f'(g(x))g'(x)$ and g' does not exist at $x = 1$, the Chain Rule cannot be used to differentiate this composite function for all x .
- (d) Yes, the composite function $(f \circ g)(x) = f(g(x)) = f(|x-1|) = |x-1|^2 = (x-1)^2$ is differentiable for all x . Its derivative is $2(x-1)$.
131. (a) Yes, the function $f(x) = x^4$ is differentiable at all real numbers x .
- (b) No, the function $g(x) = x^{1/3}$ is not differentiable at all real numbers x . The derivative does not exist at $x = 0$.
- (c) Because the Chain Rule calculates the derivative of the composition $(f \circ g)(x)$ as $f'(g(x))g'(x)$ and g' does not exist at $x = 0$, the Chain Rule cannot be used to differentiate this composite function for all x .

- (d) Yes, the composite function $(f \circ g)(x) = f(g(x)) = f(x^{1/3}) = (x^{1/3})^4 = x^{4/3}$ is differentiable for all x . Its derivative is $\frac{4}{3}x^{1/3}$.

132. Let $g(x) = 2e^x$. Then $g(x)$ is defined for all real x , $g'(x) = 2e^x = g(x)$ and $g(x) \neq f(x)$, as desired. In fact, any function of the form ce^x , where c is a real number, can be used as $g(x)$.

133. (a) Let $s(t) = 5 \sin(120\pi t)$. Then

$$v(t) = s'(t) = 5 \cos(120\pi t) \frac{d}{dt}(120\pi t) = 600\pi \cos(120\pi t) \text{ cm/sec}$$

and

$$a(t) = v'(t) = -600\pi \sin(120\pi t) \frac{d}{dt}(120\pi t) = -72000\pi^2 \sin(120\pi t) \text{ cm/sec}^2.$$

At $t = \frac{1}{240}$ seconds, the piston is at the end of its stroke, and the acceleration of the piston is

$$a\left(\frac{1}{240}\right) = -72,000\pi^2 \sin \frac{\pi}{2} \text{ cm/sec}^2 = \boxed{-72,000\pi^2 \text{ cm/sec}^2}.$$

- (b) If the piston has a mass of 1 kg, the force on the piston is

$$F = ma = \boxed{-72,000\pi^2 \text{ kg} \cdot \text{cm/sec}^2}.$$

3.2: Implicit Differentiation; Derivatives of the Inverse Trigonometric Functions

Concepts and Vocabulary

1. True. If f is a one-to-one differentiable function and if $f'(x) > 0$, then f has an inverse function whose derivative is positive.
2. True. $\frac{d}{dx} \tan^{-1} x = \frac{1}{1+x^2}$, where $-\infty < x < \infty$.
3. True. Implicit differentiation is a technique for finding the derivative of an implicitly defined function.
4. $\frac{d}{dx} \sin^{-1} x = \frac{1}{\sqrt{1-x^2}}$, where $-1 < x < 1$.
5. False. If $y^q = x^p$ for integers p and q , then $qy^{q-1} \frac{dy}{dx} = px^{p-1}$.
6. $\frac{d}{dx}(3x^{1/3}) = 3 \cdot \frac{1}{3}x^{-2/3} = \frac{1}{x^{2/3}}$.

Skill Building

7. Assume that y is a differentiable function of x and differentiate both sides of the given equation with respect to x . This yields

$$\begin{aligned} \frac{d}{dx}[x^2 + y^2] &= \frac{d}{dx}4 \\ \frac{d}{dx}x^2 + \frac{d}{dx}y^2 &= 0 \\ 2x + 2y \frac{dy}{dx} &= 0 \\ \frac{dy}{dx} &= \boxed{-\frac{x}{y}}, \end{aligned}$$

provided $y \neq 0$.

8. Assume that y is a differentiable function of x and differentiate both sides of the given equation with respect to x . This yields

$$\begin{aligned} \frac{d}{dx}[y^4 - 4x^2] &= \frac{d}{dx}4 \\ \frac{d}{dx}y^4 - 4 \frac{d}{dx}x^2 &= 0 \\ 4y^3 \frac{dy}{dx} - 8x &= 0 \\ \frac{dy}{dx} &= \boxed{\frac{2x}{y^3}}, \end{aligned}$$

provided $y \neq 0$.

9. Assume that y is a differentiable function of x and differentiate both sides of the given equation with respect to x . This yields

$$\begin{aligned}\frac{d}{dx}e^y &= \frac{d}{dx}\sin x \\ e^y \frac{dy}{dx} &= \cos x \\ \frac{dy}{dx} &= \boxed{\frac{\cos x}{e^y}}.\end{aligned}$$

10. Assume that y is a differentiable function of x and differentiate both sides of the given equation with respect to x . This yields

$$\begin{aligned}\frac{d}{dx}e^y &= \frac{d}{dx}\tan x \\ e^y \frac{dy}{dx} &= \sec^2 x \\ \frac{dy}{dx} &= \boxed{\frac{\sec^2 x}{e^y}}.\end{aligned}$$

11. Assume that y is a differentiable function of x and differentiate both sides of the given equation with respect to x . This yields

$$\begin{aligned}\frac{d}{dx}e^{x+y} &= \frac{d}{dx}y \\ e^{x+y} \frac{d}{dx}(x+y) &= \frac{dy}{dx} \\ e^{x+y} \left(1 + \frac{dy}{dx}\right) &= \frac{dy}{dx} \\ e^{x+y} + e^{x+y} \frac{dy}{dx} &= \frac{dy}{dx} \\ (e^{x+y} - 1) \frac{dy}{dx} &= -e^{x+y} \\ \frac{dy}{dx} &= \boxed{-\frac{e^{x+y}}{e^{x+y} - 1}},\end{aligned}$$

provided $e^{x+y} - 1 \neq 0$, which is equivalent to $x + y \neq 0$.

12. Assume that y is a differentiable function of x and differentiate both sides of the given equation with respect to x . This yields

$$\begin{aligned}\frac{d}{dx}e^{x+y} &= \frac{d}{dx}x^2 \\ e^{x+y} \frac{d}{dx}(x+y) &= 2x \\ e^{x+y} \left(1 + \frac{dy}{dx}\right) &= 2x \\ e^{x+y} + e^{x+y} \frac{dy}{dx} &= 2x \\ \frac{dy}{dx} &= \boxed{\frac{2x - e^{x+y}}{e^{x+y}}}.\end{aligned}$$

13. Assume that y is a differentiable function of x and differentiate both sides of the given equation with respect to x . This yields

$$\begin{aligned}\frac{d}{dx}(x^2y) &= \frac{d}{dx}5 \\ x^2\frac{dy}{dx} + y\frac{d}{dx}x^2 &= 0 \\ x^2\frac{dy}{dx} + 2xy &= 0 \\ \frac{dy}{dx} &= -\frac{2xy}{x^2} = \boxed{-\frac{2y}{x}}.\end{aligned}$$

14. Assume that y is a differentiable function of x and differentiate both sides of the given equation with respect to x . This yields

$$\begin{aligned}\frac{d}{dx}(x^3y) &= \frac{d}{dx}8 \\ x^3\frac{dy}{dx} + y\frac{d}{dx}x^3 &= 0 \\ x^3\frac{dy}{dx} + 3x^2y &= 0 \\ \frac{dy}{dx} &= -\frac{3x^2y}{x^3} = \boxed{-\frac{3y}{x}}.\end{aligned}$$

15. Assume that y is a differentiable function of x and differentiate both sides of the given equation with respect to x . This yields

$$\begin{aligned}\frac{d}{dx}[x^2 - y^2 - xy] &= \frac{d}{dx}2 \\ \frac{d}{dx}x^2 - \frac{d}{dx}y^2 - \frac{d}{dx}(xy) &= 0 \\ 2x - 2y\frac{dy}{dx} - x\frac{dy}{dx} - y\frac{d}{dx}x &= 0 \\ 2x - 2y\frac{dy}{dx} - x\frac{dy}{dx} - y &= 0 \\ -(2y + x)\frac{dy}{dx} &= y - 2x \\ \frac{dy}{dx} &= \boxed{\frac{2x - y}{2y + x}},\end{aligned}$$

provided $2y + x \neq 0$.

16. Assume that y is a differentiable function of x and differentiate both sides of the given equation with

respect to x . This yields

$$\begin{aligned}
 \frac{d}{dx}[x^2 - 4xy + y^2] &= \frac{d}{dx}y \\
 \frac{d}{dx}x^2 - 4\frac{d}{dx}(xy) + \frac{d}{dx}y^2 &= \frac{dy}{dx} \\
 2x - 4\left(x\frac{dy}{dx} + y\frac{d}{dx}x\right) + 2y\frac{dy}{dx} &= \frac{dy}{dx} \\
 2x - 4x\frac{dy}{dx} - 4y + 2y\frac{dy}{dx} &= \frac{dy}{dx} \\
 (2y - 4x - 1)\frac{dy}{dx} &= 4y - 2x \\
 \frac{dy}{dx} &= \boxed{\frac{4y - 2x}{2y - 4x - 1}},
 \end{aligned}$$

provided $2y - 4x - 1 \neq 0$.

17. Assume that y is a differentiable function of x and differentiate both sides of the given equation with respect to x . This yields

$$\begin{aligned}
 \frac{d}{dx}\left(\frac{1}{x} + \frac{1}{y}\right) &= \frac{d}{dx}1 \\
 \frac{d}{dx}\left(\frac{1}{x}\right) + \frac{d}{dx}\left(\frac{1}{y}\right) &= 0 \\
 -\frac{1}{x^2} - \frac{1}{y^2}\frac{dy}{dx} &= 0 \\
 \frac{dy}{dx} &= \boxed{-\frac{y^2}{x^2}}.
 \end{aligned}$$

18. Assume that y is a differentiable function of x and differentiate both sides of the given equation with respect to x . This yields

$$\begin{aligned}
 \frac{d}{dx}\left(\frac{1}{x} - \frac{1}{y}\right) &= \frac{d}{dx}4 \\
 \frac{d}{dx}\left(\frac{1}{x}\right) - \frac{d}{dx}\left(\frac{1}{y}\right) &= 0 \\
 -\frac{1}{x^2} + \frac{1}{y^2}\frac{dy}{dx} &= 0 \\
 \frac{dy}{dx} &= \boxed{\frac{y^2}{x^2}}.
 \end{aligned}$$

19. Assume that y is a differentiable function of x and differentiate both sides of the given equation with

respect to x . This yields

$$\begin{aligned}
 \frac{d}{dx}[x^2 + y^2] &= \frac{d}{dx} \left(\frac{2y}{x} \right) \\
 \frac{d}{dx}x^2 + \frac{d}{dx}y^2 &= \frac{x \cdot 2\frac{dy}{dx} - 2y}{x^2} \\
 2x + 2y\frac{dy}{dx} &= \frac{2}{x}\frac{dy}{dx} - \frac{2y}{x^2} \\
 \left(2y - \frac{2}{x}\right)\frac{dy}{dx} &= -2x - \frac{2y}{x^2} \\
 \frac{2xy - 2}{x}\frac{dy}{dx} &= -\frac{2x^3 + 2y}{x^2} \\
 \frac{dy}{dx} &= -\frac{x^3 + y}{x(xy - 1)} = \boxed{\frac{x^3 + y}{x(1 - xy)}},
 \end{aligned}$$

provided $1 - xy \neq 0$.

20. Assume that y is a differentiable function of x and differentiate both sides of the given equation with respect to x . This yields

$$\begin{aligned}
 \frac{d}{dx}[x^2 + y^2] &= \frac{d}{dx} \left(\frac{2y^2}{x^2} \right) \\
 \frac{d}{dx}x^2 + \frac{d}{dx}y^2 &= \frac{x^2 \cdot 4y\frac{dy}{dx} - 4xy^2}{x^4} \\
 2x + 2y\frac{dy}{dx} &= \frac{4y}{x^2}\frac{dy}{dx} - \frac{4y^2}{x^3} \\
 \left(2y - \frac{4y}{x^2}\right)\frac{dy}{dx} &= -2x - \frac{4y^2}{x^3} \\
 \frac{2x^2y - 4y}{x^2}\frac{dy}{dx} &= -\frac{2x^4 + 4y^2}{x^3} \\
 \frac{dy}{dx} &= \boxed{-\frac{x^4 + 2y^2}{xy(x^2 - 2)}},
 \end{aligned}$$

provided $y \neq 0$.

21. Assume that y is a differentiable function of x and differentiate both sides of the given equation with respect to x . This yields

$$\begin{aligned}
 \frac{d}{dx}[e^x \sin y + e^y \cos x] &= \frac{d}{dx}4 \\
 \frac{d}{dx}[e^x \sin y] + \frac{d}{dx}[e^y \cos x] &= 0 \\
 e^x \frac{d}{dx} \sin y + \sin y \frac{d}{dx}e^x + e^y \frac{d}{dx} \cos x + \cos x \frac{d}{dx}e^y &= 0 \\
 e^x \cos y \frac{dy}{dx} + e^x \sin y - e^y \sin x + e^y \cos x \frac{dy}{dx} &= 0 \\
 (e^x \cos y + e^y \cos x) \frac{dy}{dx} &= e^y \sin x - e^x \sin y \\
 \frac{dy}{dx} &= \boxed{\frac{e^y \sin x - e^x \sin y}{e^x \cos y + e^y \cos x}},
 \end{aligned}$$

provided $e^x \cos y + e^y \cos x \neq 0$.

22. Assume that y is a differentiable function of x and differentiate both sides of the given equation with respect to x . This yields

$$\begin{aligned}
 \frac{d}{dx}[e^y \cos x + e^{-x} \sin y] &= \frac{d}{dx} 10 \\
 \frac{d}{dx}[e^y \cos x] + \frac{d}{dx}[e^{-x} \sin y] &= 0 \\
 e^y \frac{d}{dx} \cos x + \cos x \frac{d}{dx} e^y + e^{-x} \frac{d}{dx} \sin y + \sin y \frac{d}{dx} e^{-x} &= 0 \\
 -e^y \sin x + e^y \cos x \frac{dy}{dx} + e^{-x} \cos y \frac{dy}{dx} - e^{-x} \sin y &= 0 \\
 (e^y \cos x + e^{-x} \cos y) \frac{dy}{dx} &= e^y \sin x + e^{-x} \sin y \\
 \frac{dy}{dx} &= \boxed{\frac{e^y \sin x + e^{-x} \sin y}{e^y \cos x + e^{-x} \cos y}},
 \end{aligned}$$

provided $e^y \cos x + e^{-x} \cos y \neq 0$.

23. Assume that y is a differentiable function of x and differentiate both sides of the given equation with respect to x . This yields

$$\begin{aligned}
 \frac{d}{dx}[(x^2 + y)^3] &= \frac{d}{dx} y \\
 3(x^2 + y)^2 \frac{d}{dx}(x^2 + y) &= \frac{dy}{dx} \\
 3(x^2 + y)^2 \left(\frac{d}{dx} x^2 + \frac{dy}{dx} \right) &= \frac{dy}{dx} \\
 3(x^2 + y)^2 \left(2x + \frac{dy}{dx} \right) &= \frac{dy}{dx} \\
 [3(x^2 + y)^2 - 1] \frac{dy}{dx} &= -6x(x^2 + y)^2 \\
 \frac{dy}{dx} &= \boxed{-\frac{6x(x^2 + y)^2}{3(x^2 + y)^2 - 1}},
 \end{aligned}$$

provided $3(x^2 + y)^2 - 1 \neq 0$.

24. Assume that y is a differentiable function of x and differentiate both sides of the given equation with respect to x . This yields

$$\begin{aligned}
 \frac{d}{dx}[(x + y^2)^3] &= \frac{d}{dx}(3x) \\
 3(x + y^2)^2 \frac{d}{dx}(x + y^2) &= 3 \\
 3(x + y^2)^2 \left(\frac{d}{dx} x + \frac{d}{dx} y^2 \right) &= 3 \\
 3(x + y^2)^2 \left(1 + 2y \frac{dy}{dx} \right) &= 3 \\
 6y(x + y^2)^2 \frac{dy}{dx} &= 3 - 3(x + y^2)^2 \\
 \frac{dy}{dx} &= \boxed{\frac{1 - (x + y^2)^2}{2y(x + y^2)^2}},
 \end{aligned}$$

provided $y(x + y^2) \neq 0$.

25. Assume that y is a differentiable function of x and differentiate both sides of the given equation with respect to x . This yields

$$\begin{aligned}
 \frac{d}{dx}y &= \frac{d}{dx}\tan(x-y) \\
 \frac{dy}{dx} &= \sec^2(x-y) \cdot \frac{d}{dx}(x-y) \\
 \frac{dy}{dx} &= \sec^2(x-y) \cdot \left(\frac{d}{dx}x - \frac{dy}{dx}\right) \\
 \frac{dy}{dx} &= \sec^2(x-y) \cdot \left(1 - \frac{dy}{dx}\right) \\
 (1 + \sec^2(x-y))\frac{dy}{dx} &= \sec^2(x-y) \\
 \frac{dy}{dx} &= \boxed{\frac{\sec^2(x-y)}{1 + \sec^2(x-y)}}.
 \end{aligned}$$

26. Assume that y is a differentiable function of x and differentiate both sides of the given equation with respect to x . This yields

$$\begin{aligned}
 \frac{d}{dx}y &= \frac{d}{dx}\cos(x+y) \\
 \frac{dy}{dx} &= -\sin(x+y) \cdot \frac{d}{dx}(x+y) \\
 \frac{dy}{dx} &= -\sin(x+y) \cdot \left(\frac{d}{dx}x + \frac{dy}{dx}\right) \\
 \frac{dy}{dx} &= -\sin(x+y) \cdot \left(1 + \frac{dy}{dx}\right) \\
 (1 + \sin(x+y))\frac{dy}{dx} &= -\sin(x+y) \\
 \frac{dy}{dx} &= \boxed{-\frac{\sin(x+y)}{1 + \sin(x+y)}},
 \end{aligned}$$

provided $1 + \sin(x+y) \neq 0$.

27. Assume that y is a differentiable function of x and differentiate both sides of the given equation with respect to x . This yields

$$\begin{aligned}
 \frac{d}{dx}y &= \frac{d}{dx}[x \sin y] \\
 \frac{dy}{dx} &= x \frac{d}{dx}\sin y + \sin y \frac{d}{dx}x \\
 \frac{dy}{dx} &= x \cos y \frac{dy}{dx} + \sin y \\
 (1 - x \cos y)\frac{dy}{dx} &= \sin y \\
 \frac{dy}{dx} &= \boxed{\frac{\sin y}{1 - x \cos y}},
 \end{aligned}$$

provided $1 - x \cos y \neq 0$.

28. Assume that y is a differentiable function of x and differentiate both sides of the given equation with

respect to x . This yields

$$\begin{aligned}
 \frac{d}{dx}y &= \frac{d}{dx}[x \cos y] \\
 \frac{dy}{dx} &= x \frac{d}{dx} \cos y + \cos y \frac{d}{dx}x \\
 \frac{dy}{dx} &= -x \sin y \frac{dy}{dx} + \cos y \\
 (1 + x \sin y) \frac{dy}{dx} &= \cos y \\
 \frac{dy}{dx} &= \boxed{\frac{\cos y}{1 + x \sin y}},
 \end{aligned}$$

provided $1 + x \sin y \neq 0$.

29. Assume that y is a differentiable function of x and differentiate both sides of the given equation with respect to x . This yields

$$\begin{aligned}
 \frac{d}{dx}(x^2 y) &= \frac{d}{dx}e^{xy} \\
 x^2 \frac{dy}{dx} + y \frac{d}{dx}x^2 &= e^{xy} \frac{d}{dx}(xy) \\
 x^2 \frac{dy}{dx} + 2xy &= e^{xy} \left(x \frac{dy}{dx} + y \frac{d}{dx}x \right) \\
 x^2 \frac{dy}{dx} + 2xy &= xe^{xy} \frac{dy}{dx} + ye^{xy} \\
 (x^2 - xe^{xy}) \frac{dy}{dx} &= ye^{xy} - 2xy \\
 \frac{dy}{dx} &= \boxed{\frac{ye^{xy} - 2xy}{x^2 - xe^{xy}}},
 \end{aligned}$$

provided $x^2 - xe^{xy} \neq 0$.

30. Assume that y is a differentiable function of x and differentiate both sides of the given equation with respect to x . This yields

$$\begin{aligned}
 \frac{d}{dx}(ye^x) &= \frac{d}{dx}(y - x) \\
 y \frac{d}{dx}e^x + e^x \frac{dy}{dx} &= \frac{dy}{dx} - \frac{d}{dx}x \\
 ye^x + e^x \frac{dy}{dx} &= \frac{dy}{dx} - 1 \\
 (e^x - 1) \frac{dy}{dx} &= -(1 + ye^x) \\
 \frac{dy}{dx} &= \boxed{-\frac{1 + ye^x}{e^x - 1}}.
 \end{aligned}$$

31. Let $y = x^{2/3} + 4$. Then $y' = \frac{2}{3}x^{-1/3} = \boxed{\frac{2}{3x^{1/3}}}$.

32. Let $y = x^{1/3} - 1$. Then $y' = \frac{1}{3}x^{-2/3} = \boxed{\frac{1}{3x^{2/3}}}$.

33. Let $y = \sqrt[3]{x^2} = x^{2/3}$. Then $y' = \frac{2}{3}x^{-1/3} = \boxed{\frac{2}{3x^{1/3}}}$.

34. Let $y = \sqrt[4]{x^5} = x^{5/4}$. Then $y' = \boxed{\frac{5}{4}x^{1/4}}$.

35. Let $y = \sqrt[3]{x} - \frac{1}{\sqrt[3]{x}} = x^{1/3} - x^{-1/3}$. Then $y' = \frac{1}{3}x^{-2/3} + \frac{1}{3}x^{-4/3} = \boxed{\frac{1}{3x^{2/3}} + \frac{1}{3x^{4/3}}}$.

36. Let $y = \sqrt{x} + \frac{1}{\sqrt{x}} = x^{1/2} + x^{-1/2}$. Then $y' = \frac{1}{2}x^{-1/2} - \frac{1}{2}x^{-3/2} = \boxed{\frac{1}{2x^{1/2}} - \frac{1}{2x^{3/2}}}$.

37. Let $y = (x^3 - 1)^{1/2}$. Then

$$y' = \frac{1}{2}(x^3 - 1)^{-1/2} \frac{d}{dx}(x^3 - 1) = \frac{1}{2}(x^3 - 1)^{-1/2}(3x^2) = \boxed{\frac{3x^2}{2(x^3 - 1)^{1/2}}}.$$

38. Let $y = (x^2 - 1)^{1/3}$. Then

$$y' = \frac{1}{3}(x^2 - 1)^{-2/3} \frac{d}{dx}(x^2 - 1) = \frac{1}{3}(x^2 - 1)^{-2/3}(2x) = \boxed{\frac{2x}{3(x^2 - 1)^{2/3}}}.$$

39. Let $y = x\sqrt{x^2 - 1}$. Then

$$\begin{aligned} y' &= x \frac{d}{dx} \sqrt{x^2 - 1} + \sqrt{x^2 - 1} \frac{d}{dx} x = x \cdot \frac{1}{2}(x^2 - 1)^{-1/2} \frac{d}{dx}(x^2 - 1) + \sqrt{x^2 - 1} \\ &= \frac{x(2x)}{2(x^2 - 1)^{1/2}} + (x^2 - 1)^{1/2} = \boxed{\frac{x^2}{(x^2 - 1)^{1/2}} + (x^2 - 1)^{1/2}}. \end{aligned}$$

40. Let $y = x\sqrt{x^3 + 1}$. Then

$$\begin{aligned} y' &= x \frac{d}{dx} \sqrt{x^3 + 1} + \sqrt{x^3 + 1} \frac{d}{dx} x = x \cdot \frac{1}{2}(x^3 + 1)^{-1/2} \frac{d}{dx}(x^3 + 1) + \sqrt{x^3 + 1} \\ &= \frac{x(3x^2)}{2(x^3 + 1)^{1/2}} + (x^3 + 1)^{1/2} = \boxed{\frac{3x^3}{2(x^3 + 1)^{1/2}} + (x^3 + 1)^{1/2}}. \end{aligned}$$

41. Let $y = e^{\sqrt{x^2 - 9}}$. Then

$$y' = e^{\sqrt{x^2 - 9}} \frac{d}{dx} \sqrt{x^2 - 9} = e^{\sqrt{x^2 - 9}} \cdot \frac{1}{2}(x^2 - 9)^{-1/2} \frac{d}{dx}(x^2 - 9) = e^{(x^2 - 9)^{1/2}} \frac{2x}{2(x^2 - 9)^{1/2}} = \boxed{\frac{xe^{(x^2 - 9)^{1/2}}}{(x^2 - 9)^{1/2}}}.$$

42. Note that $\sqrt{e^x} = (e^x)^{1/2} = e^{x/2}$. Therefore, $y' = \boxed{\frac{1}{2}e^{x/2}}$.

43. Let $y = (x^2 \cos x)^{3/2}$. Then

$$\begin{aligned} y' &= \frac{3}{2}(x^2 \cos x)^{1/2} \frac{d}{dx}(x^2 \cos x) = \frac{3}{2}(x^2 \cos x)^{1/2} \left(x^2 \frac{d}{dx} \cos x + \cos x \frac{d}{dx} x^2 \right) \\ &= \boxed{\frac{3}{2}(x^2 \cos x)^{1/2} (-x^2 \sin x + 2x \cos x)}. \end{aligned}$$

44. Let $y = (x^2 \sin x)^{3/2}$. Then

$$\begin{aligned} y' &= \frac{3}{2}(x^2 \sin x)^{1/2} \frac{d}{dx}(x^2 \sin x) = \frac{3}{2}(x^2 \sin x)^{1/2} \left(x^2 \frac{d}{dx} \sin x + \sin x \frac{d}{dx} x^2 \right) \\ &= \boxed{\frac{3}{2}(x^2 \sin x)^{1/2} (x^2 \cos x + 2x \sin x)}. \end{aligned}$$

45. Let $y = (x^2 - 3)^{3/2}(6x + 1)^{5/3}$. Then

$$\begin{aligned}
 y' &= (x^2 - 3)^{3/2} \frac{d}{dx} (6x + 1)^{5/3} + (6x + 1)^{5/3} \frac{d}{dx} (x^2 - 3)^{3/2} \\
 &= (x^2 - 3)^{3/2} \cdot \frac{5}{3} (6x + 1)^{2/3} \frac{d}{dx} (6x + 1) + (6x + 1)^{5/3} \cdot \frac{3}{2} (x^2 - 3)^{1/2} \frac{d}{dx} (x^2 - 3) \\
 &= 10(x^2 - 3)^{3/2}(6x + 1)^{2/3} + 3x(6x + 1)^{5/3}(x^2 - 3)^{1/2} \\
 &= (x^2 - 3)^{1/2}(6x + 1)^{2/3}(10(x^2 - 3) + 3x(6x + 1)) \\
 &= \boxed{(x^2 - 3)^{1/2}(6x + 1)^{2/3}(28x^2 + 3x - 30)}.
 \end{aligned}$$

46. Let $y = \frac{(2x^3 - 1)^{4/3}}{(3x + 4)^{5/2}}$. Then

$$\begin{aligned}
 y' &= \frac{(3x + 4)^{5/2} \frac{d}{dx} (2x^3 - 1)^{4/3} - (2x^3 - 1)^{4/3} \frac{d}{dx} (3x + 4)^{5/2}}{[(3x + 4)^{5/2}]^2} \\
 &= \frac{(3x + 4)^{5/2} \cdot \frac{4}{3} (2x^3 - 1)^{1/3} \frac{d}{dx} (2x^3 - 1) - (2x^3 - 1)^{4/3} \cdot \frac{5}{2} (3x + 4)^{3/2} \frac{d}{dx} (3x + 4)}{(3x + 4)^5} \\
 &= \frac{8x^2(2x^3 - 1)^{1/3}(3x + 4)^{5/2} - \frac{15}{2}(2x^3 - 1)^{4/3}(3x + 4)^{3/2}}{(3x + 4)^5} \\
 &= \frac{(2x^3 - 1)^{1/3}(3x + 4)^{3/2} (8x^2(3x + 4) - \frac{15}{2}(2x^3 - 1))}{(3x + 4)^5} \\
 &= \boxed{\frac{(2x^3 - 1)^{1/3}(9x^3 + 32x^2 + \frac{15}{2})}{(3x + 4)^{7/2}}}.
 \end{aligned}$$

47. Let $y = \sin^{-1}(4x)$. Then $y' = \frac{1}{\sqrt{1 - (4x)^2}} \frac{d}{dx} (4x) = \boxed{\frac{4}{\sqrt{1 - 16x^2}}}.$

48. Let $y = \cos^{-1} x^2$. Then $y' = -\frac{1}{\sqrt{1 - (x^2)^2}} \frac{d}{dx} x^2 = \boxed{-\frac{2x}{\sqrt{1 - x^4}}}.$

49. Let $y = \sec^{-1}(3x)$. Then $y' = \frac{1}{3x\sqrt{(3x)^2 - 1}} \frac{d}{dx} (3x) = \boxed{\frac{1}{x\sqrt{9x^2 - 1}}}.$

50. Let $y = \tan^{-1} \left(\frac{1}{x} \right)$. Then $y' = \frac{1}{1 + (\frac{1}{x})^2} \frac{d}{dx} \left(\frac{1}{x} \right) = \frac{1}{1 + \frac{1}{x^2}} \left(-\frac{1}{x^2} \right) = \boxed{-\frac{1}{x^2 + 1}}.$

51. Let $y = \sin^{-1} e^x$. Then $y' = \frac{1}{\sqrt{1 - (e^x)^2}} \frac{d}{dx} e^x = \boxed{\frac{e^x}{\sqrt{1 - e^{2x}}}}.$

52. Let $y = \sin^{-1}(1 - x^2)$. Then

$$y' = \frac{1}{\sqrt{1 - (1 - x^2)^2}} \frac{d}{dx} (1 - x^2) = \frac{-2x}{\sqrt{1 - 1 + 2x^2 - x^4}} = -\frac{2x}{\sqrt{2x^2 - x^4}} = \boxed{-\frac{2x}{|x|\sqrt{2 - x^2}}}.$$

53. Let $y = x(\sin^{-1} x)$. Then $y' = x \frac{d}{dx} \sin^{-1} x + \sin^{-1} x \frac{d}{dx} x = \boxed{\frac{x}{\sqrt{1 - x^2}} + \sin^{-1} x}.$

54. Let $y = x \tan^{-1}(x+1)$. Then

$$\begin{aligned} y' &= x \frac{d}{dx} \tan^{-1}(x+1) + \tan^{-1}(x+1) \frac{d}{dx} x = \frac{x}{1+(x+1)^2} \frac{d}{dx} (x+1) + \tan^{-1}(x+1) \\ &= \boxed{\frac{x}{x^2+2x+2} + \tan^{-1}(x+1)}. \end{aligned}$$

55. Let $y = \tan^{-1}(\sin x)$. Then $y' = \frac{1}{1+\sin^2 x} \frac{d}{dx} \sin x = \boxed{\frac{\cos x}{1+\sin^2 x}}$.

56. Let $y = \sin(\tan^{-1} x)$. Then $y' = \cos(\tan^{-1} x) \frac{d}{dx} \tan^{-1} x = \boxed{\frac{\cos(\tan^{-1} x)}{1+x^2}}$.

57. Let $x^2 + y^2 = 4$. Then

$$\begin{aligned} \frac{d}{dx} [x^2 + y^2] &= \frac{d}{dx} 4 \\ \frac{d}{dx} x^2 + \frac{d}{dx} y^2 &= 0 \\ 2x + 2y \frac{dy}{dx} &= 0 \\ y' = \frac{dy}{dx} &= \boxed{-\frac{x}{y}}, \end{aligned}$$

provided $y \neq 0$. Next,

$$y'' = \frac{d}{dx} \left(-\frac{x}{y} \right) = -\frac{y \frac{d}{dx} x - x \frac{dy}{dx}}{y^2} = -\frac{y - x \left(-\frac{x}{y} \right)}{y^2} = \boxed{-\frac{y^2 + x^2}{y^3}},$$

provided $y \neq 0$. Using the original equation, $x^2 + y^2 = 4$, the second derivative can be simplified to

$$y'' = -\frac{4}{y^3}.$$

58. Let $x^2 - y^2 = 1$. Then

$$\begin{aligned} \frac{d}{dx} [x^2 - y^2] &= \frac{d}{dx} 1 \\ \frac{d}{dx} x^2 - \frac{d}{dx} y^2 &= 0 \\ 2x - 2y \frac{dy}{dx} &= 0 \\ y' = \frac{dy}{dx} &= \boxed{\frac{x}{y}}, \end{aligned}$$

provided $y \neq 0$. Next,

$$y'' = \frac{d}{dx} \left(\frac{x}{y} \right) = \frac{y \frac{d}{dx} x - x \frac{dy}{dx}}{y^2} = \frac{y - x \left(\frac{x}{y} \right)}{y^2} = \boxed{\frac{y^2 - x^2}{y^3}},$$

provided $y \neq 0$. Using the original equation, $x^2 - y^2 = 1$, the second derivative can be simplified to

$$y'' = -\frac{1}{y^3}.$$

59. Let $xy^2 + yx^2 = 2$. Then

$$\begin{aligned}
 \frac{d}{dx}[xy^2 + yx^2] &= \frac{d}{dx}2 \\
 \frac{d}{dx}(xy^2) + \frac{d}{dx}yx^2 &= 0 \\
 x\frac{d}{dx}y^2 + y^2\frac{d}{dx}x + y\frac{d}{dx}x^2 + x^2\frac{dy}{dx} &= 0 \\
 2xy\frac{dy}{dx} + y^2 + 2xy + x^2\frac{dy}{dx} &= 0 \\
 (2xy + x^2)\frac{dy}{dx} &= -(2xy + y^2) \\
 y' = \frac{dy}{dx} &= \boxed{-\frac{2xy + y^2}{2xy + x^2}},
 \end{aligned}$$

provided $2xy + x^2 \neq 0$. Next,

$$\begin{aligned}
 y'' &= -\frac{d}{dx}\left(\frac{2xy + y^2}{2xy + x^2}\right) = -\frac{(2xy + x^2)\frac{d}{dx}(2xy + y^2) - (2xy + y^2)\frac{d}{dx}(2xy + x^2)}{(2xy + x^2)^2} \\
 &= -\frac{(2xy + x^2)\left(2x\frac{dy}{dx} + 2y + 2y\frac{dy}{dx}\right) - (2xy + y^2)\left(2x\frac{dy}{dx} + 2y + 2x\right)}{(2xy + x^2)^2} \\
 &= -\frac{4xy^2 + 2x^2y - 4xy^2 - 4x^2y - 2y^3 - 2xy^2 + (4x^2y + 4xy^2 + 2x^3 + 2x^2y - 4x^2y - 2xy^2)\frac{dy}{dx}}{(2xy + x^2)^2} \\
 &= -\frac{-2(x^2y + xy^2 + y^3) + 2(x^2y + xy^2 + x^3)\frac{dy}{dx}}{(2xy + x^2)^2} = \frac{2(x^2 + xy + y^2)\left[y - x\left(-\frac{2xy + y^2}{2xy + x^2}\right)\right]}{(2xy + x^2)^2} \\
 &= -\frac{2(x^2 + xy + y^2)(2xy^2 + x^2y + 2x^2y + xy^2)}{(2xy + x^2)^3} = \frac{6(x^2 + xy + y^2)(xy^2 + x^2y)}{(2xy + x^2)^3} \\
 &= \boxed{\frac{6xy(x + y)(x^2 + xy + y^2)}{(2xy + x^2)^3}}.
 \end{aligned}$$

provided $2xy + x^2 \neq 0$. Using the original equation, $xy^2 + yx^2 = 2$, the second derivative can be simplified to

$$y'' = \frac{6(2)(x^2 + xy + y^2)}{(2xy + x^2)^3} = \frac{12(x^2 + xy + y^2)}{(2xy + x^2)^3}.$$

60. Let $4xy = x^2 + y^2$. Then

$$\begin{aligned}
 \frac{d}{dx}(4xy) &= \frac{d}{dx}[x^2 + y^2] \\
 4x\frac{dy}{dx} + 4y\frac{d}{dx}x &= \frac{d}{dx}x^2 + \frac{d}{dx}y^2 \\
 4x\frac{dy}{dx} + 4y &= 2x + 2y\frac{dy}{dx} \\
 (4x - 2y)\frac{dy}{dx} &= 2x - 4y \\
 y' = \frac{dy}{dx} &= \boxed{\frac{x - 2y}{2x - y}}.
 \end{aligned}$$

provided $2x - y \neq 0$. Next,

$$\begin{aligned}
 y'' &= \frac{d}{dx} \left(\frac{x - 2y}{2x - y} \right) = \frac{(2x - y) \frac{d}{dx}(x - 2y) - (x - 2y) \frac{d}{dx}(2x - y)}{(2x - y)^2} \\
 &= \frac{(2x - y) \left(1 - 2 \frac{dy}{dx} \right) - (x - 2y) \left(2 - \frac{dy}{dx} \right)}{(2x - y)^2} \\
 &= \frac{2x - y - 2x + 4y + (2y - 4x + x - 2y) \frac{dy}{dx}}{(2x - y)^2} \\
 &= \frac{3y - 3x \frac{x - 2y}{2x - y}}{(2x - y)^2} = \frac{3y(2x - y) - 3x(x - 2y)}{(2x - y)^3} \\
 &= \frac{6xy - 3y^2 - 3x^2 + 6xy}{(2x - y)^3} = \boxed{\frac{3(4xy - x^2 - y^2)}{(2x - y)^3}},
 \end{aligned}$$

provided $2x - y \neq 0$. Using the original equation, $4xy = x^2 + y^2$, the second derivative can be simplified to

$$y'' = \frac{3(0)}{(2x - y)^3} = 0.$$

61. Let $y = \sqrt{x^2 + 1}$. Then

$$y' = \frac{1}{2}(x^2 + 1)^{-1/2} \frac{d}{dx}(x^2 + 1) = \boxed{\frac{x}{(x^2 + 1)^{1/2}}},$$

and

$$\begin{aligned}
 y'' &= \frac{\sqrt{x^2 + 1} \frac{d}{dx}x - x \frac{d}{dx}\sqrt{x^2 + 1}}{(\sqrt{x^2 + 1})^2} = \frac{\sqrt{x^2 + 1} - x \cdot \frac{1}{2}(x^2 + 1)^{-1/2} \frac{d}{dx}(x^2 + 1)}{x^2 + 1} \\
 &= \frac{\sqrt{x^2 + 1} - \frac{x^2}{\sqrt{x^2 + 1}}}{x^2 + 1} = \frac{(x^2 + 1) - x^2}{(x^2 + 1)^{3/2}} = \boxed{\frac{1}{(x^2 + 1)^{3/2}}}.
 \end{aligned}$$

62. Let $y = \sqrt{4 - x^2}$. Then

$$y' = \frac{1}{2}(4 - x^2)^{-1/2} \frac{d}{dx}(4 - x^2) = \boxed{-\frac{x}{(4 - x^2)^{1/2}}},$$

and

$$\begin{aligned}
 y'' &= -\frac{\sqrt{4 - x^2} \frac{d}{dx}x - x \frac{d}{dx}\sqrt{4 - x^2}}{(\sqrt{4 - x^2})^2} = -\frac{\sqrt{4 - x^2} - x \cdot \frac{1}{2}(4 - x^2)^{-1/2} \frac{d}{dx}(4 - x^2)}{4 - x^2} \\
 &= -\frac{\sqrt{4 - x^2} + \frac{x^2}{\sqrt{4 - x^2}}}{4 - x^2} = -\frac{(4 - x^2) + x^2}{(4 - x^2)^{3/2}} = \boxed{-\frac{4}{(4 - x^2)^{3/2}}}.
 \end{aligned}$$

63. (a) Let $x^2 + y^2 = 5$. Then

$$\begin{aligned}
 \frac{d}{dx}[x^2 + y^2] &= \frac{d}{dx}5 \\
 \frac{d}{dx}x^2 + \frac{d}{dx}y^2 &= 0 \\
 2x + 2y \frac{dy}{dx} &= 0 \\
 \frac{dy}{dx} &= -\frac{x}{y}.
 \end{aligned}$$

Therefore, the slope of the tangent line to the graph of the given equation at the point $(1, 2)$ is

$$m_{\text{tan}} = \boxed{-\frac{1}{2}}.$$

(b) The equation of the tangent line is

$$y - 2 = -\frac{1}{2}(x - 1) \quad \text{or} \quad \boxed{y = -\frac{x}{2} + \frac{5}{2}}.$$

(c) The figure below displays the graph of the equation $x^2 + y^2 = 5$ as the solid curve and the tangent line at $(1, 2)$ as the dashed curve.

64. (a) Let $(x - 3)^2 + (y + 4)^2 = 25$. Then

$$\begin{aligned} \frac{d}{dx}[(x - 3)^2 + (y + 4)^2] &= \frac{d}{dx}25 \\ \frac{d}{dx}(x - 3)^2 + \frac{d}{dx}(y + 4)^2 &= 0 \\ 2(x - 3)\frac{d}{dx}(x - 3) + 2(y + 4)\frac{d}{dx}(y + 4) &= 0 \\ 2(x - 3) + 2(y + 4)\frac{dy}{dx} &= 0 \\ \frac{dy}{dx} &= -\frac{x - 3}{y + 4}. \end{aligned}$$

Therefore, the slope of the tangent line to the graph of the given equation at the point $(0, 0)$ is

$$m_{\text{tan}} = -\frac{0 - 3}{0 + 4} = \boxed{\frac{3}{4}}.$$

(b) The equation of the tangent line is

$$y - 0 = \frac{3}{4}(x - 0) \quad \text{or} \quad \boxed{y = \frac{3}{4}x}.$$

(c) The figure below displays the graph of the equation $(x - 3)^2 + (y + 4)^2 = 25$ as the solid curve and the tangent line at $(0, 0)$ as the dashed curve.

65. (a) Let $x^2 - y^2 = 8$. Then

$$\begin{aligned}\frac{d}{dx}[x^2 - y^2] &= \frac{d}{dx}8 \\ \frac{d}{dx}x^2 - \frac{d}{dx}y^2 &= 0 \\ 2x - 2y\frac{dy}{dx} &= 0 \\ \frac{dy}{dx} &= \frac{x}{y}.\end{aligned}$$

Therefore, the slope of the tangent line to the graph of the given equation at the point $(3, 1)$ is

$$m_{\text{tan}} = \frac{3}{1} = \boxed{3}.$$

- (b) The equation of the tangent line is

$$y - 1 = 3(x - 3) \quad \text{or} \quad \boxed{y = 3x - 8}.$$

- (c) The figure below displays the graph of the equation $x^2 - y^2 = 8$ as the solid curve and the tangent line at $(3, 1)$ as the dashed curve.

66. (a) Let $y^2 - 3x^2 = 6$. Then

$$\begin{aligned}\frac{d}{dx}[y^2 - 3x^2] &= \frac{d}{dx}6 \\ \frac{d}{dx}y^2 - 3\frac{d}{dx}x^2 &= 0 \\ 2y\frac{dy}{dx} - 6x &= 0 \\ \frac{dy}{dx} &= \frac{3x}{y}.\end{aligned}$$

Therefore, the slope of the tangent line to the graph of the given equation at the point $(1, -3)$ is

$$m_{\text{tan}} = \frac{3(1)}{-3} = \boxed{-1}.$$

(b) The equation of the tangent line is

$$y - (-3) = -1(x - 1) \quad \text{or} \quad \boxed{y = -x - 2}.$$

(c) The figure below displays the graph of the equation $y^2 - 3x^2 = 6$ as the solid curve and the tangent line at $(1, -3)$ as the dashed curve.

67. (a) Let $\frac{x^2}{4} + \frac{y^2}{3} = 1$. Then

$$\begin{aligned} \frac{d}{dx} \left[\frac{x^2}{4} + \frac{y^2}{3} \right] &= \frac{d}{dx} 1 \\ \frac{d}{dx} \left(\frac{x^2}{4} \right) + \frac{d}{dx} \left(\frac{y^2}{3} \right) &= 0 \\ \frac{1}{2}x + \frac{2}{3}y \frac{dy}{dx} &= 0 \\ \frac{dy}{dx} &= -\frac{3x}{4y}. \end{aligned}$$

Therefore, the slope of the tangent line to the graph of the given equation at the point $\left(-1, \frac{3}{2}\right)$ is

$$m_{\text{tan}} = -\frac{3(-1)}{4(3/2)} = \boxed{\frac{1}{2}}.$$

(b) The equation of the tangent line is

$$y - \frac{3}{2} = \frac{1}{2}(x + 1) \quad \text{or} \quad \boxed{y = \frac{x}{2} + 2}.$$

(c) The figure below displays the graph of the equation $\frac{x^2}{4} + \frac{y^2}{3} = 1$ as the solid curve and the tangent line at $\left(-1, \frac{3}{2}\right)$ as the dashed curve.

68. (a) Let $x^2 + \frac{y^2}{4} = 1$. Then

$$\begin{aligned}\frac{d}{dx} \left[x^2 + \frac{y^2}{4} \right] &= \frac{d}{dx} 1 \\ \frac{d}{dx} x^2 + \frac{d}{dx} \left(\frac{y^2}{4} \right) &= 0 \\ 2x + \frac{1}{2} y \frac{dy}{dx} &= 0 \\ \frac{dy}{dx} &= -\frac{4x}{y}.\end{aligned}$$

Therefore, the slope of the tangent line to the graph of the given equation at the point $\left(\frac{1}{2}, \sqrt{3}\right)$ is

$$m_{\text{tan}} = -\frac{4(1/2)}{\sqrt{3}} = \boxed{-\frac{2}{\sqrt{3}}}.$$

- (b) The equation of the tangent line is

$$y - \sqrt{3} = -\frac{2}{\sqrt{3}} \left(x - \frac{1}{2} \right) \quad \text{or} \quad \boxed{y = -\frac{2}{\sqrt{3}}x + \sqrt{3} + \frac{1}{\sqrt{3}}}.$$

- (c) The figure below displays the graph of the equation $x^2 + \frac{y^2}{4} = 1$ as the solid curve and the tangent line at $\left(\frac{1}{2}, \sqrt{3}\right)$ as the dashed curve.

69. Let $3x^2y + 2y^3 = 5x^2$. Then

$$\begin{aligned}\frac{d}{dx}[3x^2y + 2y^3] &= \frac{d}{dx}(5x^2) \\ \frac{d}{dx}(3x^2y) + \frac{d}{dx}(2y^3) &= 10x \\ 3x^2\frac{dy}{dx} + y\frac{d}{dx}(3x^2) + 6y^2\frac{dy}{dx} &= 10x \\ (3x^2 + 6y^2)\frac{dy}{dx} + 6xy &= 10x \\ \frac{dy}{dx} &= \frac{10x - 6xy}{3x^2 + 6y^2}\end{aligned}$$

and, at the point $(-1, 1)$,

$$\frac{dy}{dx} = \frac{10(-1) - 6(-1)(1)}{3(-1)^2 + 6(1)^2} = \boxed{-\frac{4}{9}}.$$

Next,

$$\begin{aligned}\frac{d^2y}{dx^2} &= \frac{d}{dx}\left(\frac{10x - 6xy}{3x^2 + 6y^2}\right) = \frac{(3x^2 + 6y^2)\frac{d}{dx}(10x - 6xy) - (10x - 6xy)\frac{d}{dx}(3x^2 + 6y^2)}{(3x^2 + 6y^2)^2} \\ &= \frac{(3x^2 + 6y^2)\left(10 - 6x\frac{dy}{dx} - 6y\right) - (10x - 6xy)\left(6x + 12y\frac{dy}{dx}\right)}{(3x^2 + 6y^2)^2},\end{aligned}$$

and, at the point $(-1, 1)$,

$$\begin{aligned}\frac{d^2y}{dx^2} &= \frac{(3 + 6)\left(10 + 6\left(-\frac{4}{9}\right) - 6\right) - (-10 + 6)\left(-6 + 12\left(-\frac{4}{9}\right)\right)}{(3 + 6)^2} \\ &= \frac{9 \cdot \frac{4}{3} - (-4) \cdot \left(-\frac{34}{3}\right)}{9^2} = \boxed{-\frac{100}{243}}.\end{aligned}$$

70. Let $4x^3 + 2y^3 = x + y$. Then

$$\begin{aligned}\frac{d}{dx}[4x^3 + 2y^3] &= \frac{d}{dx}[x + y] \\ 12x^2 + 6y^2\frac{dy}{dx} &= 1 + \frac{dy}{dx} \\ (6y^2 - 1)\frac{dy}{dx} &= 1 - 12x^2 \\ \frac{dy}{dx} &= \frac{1 - 12x^2}{6y^2 - 1}\end{aligned}$$

and, at the point $(0, 0)$,

$$\frac{dy}{dx} = \frac{1 - 12(0)^2}{6(0)^2 - 1} = \frac{1}{-1} = \boxed{-1}.$$

Next,

$$\begin{aligned}\frac{d^2y}{dx^2} &= \frac{d}{dx}\left(\frac{1 - 12x^2}{6y^2 - 1}\right) = \frac{(6y^2 - 1)\frac{d}{dx}(1 - 12x^2) - (1 - 12x^2)\frac{d}{dx}(6y^2 - 1)}{(6y^2 - 1)^2} \\ &= \frac{-24x(6y^2 - 1) - 12y(1 - 12x^2)\frac{dy}{dx}}{(6y^2 - 1)^2},\end{aligned}$$

and, at the point $(0, 0)$,

$$\frac{d^2y}{dx^2} = \frac{-24(0)(6(0)^2 - 1) - 12(0)(1 - 12(0)^2)(-1)}{(6(0)^2 - 1)^2} = \frac{0}{1} = \boxed{0}.$$

71. Because f and g are inverse functions,

$$g'(4) = \frac{1}{f'(g(4))} = \frac{1}{f'(0)} = \frac{1}{-2} = \boxed{-\frac{1}{2}}.$$

72. Because f and g are inverse functions,

$$g'(-2) = \frac{1}{f'(g(-2))} = \frac{1}{f'(1)} = \boxed{\frac{1}{4}}.$$

73. Because f and g are inverse functions,

$$f'(-2) = \frac{1}{g'(f(-2))} = \frac{1}{g'(3)} = \frac{1}{1/2} = \boxed{2}.$$

74. Because f and g are inverse functions,

$$f'(0) = \frac{1}{g'(f(0))} = \frac{1}{g'(-1)} = \frac{1}{-1/3} = \boxed{-3}.$$

75. Let $f(x) = x^3 + 2x$. First note that $f(0) = 0$, $f(1) = 3$, and $f'(x) = 3x^2 + 2$. Because g is the inverse function of f , it follows that $g(0) = 0$, $g(3) = 1$,

$$g'(0) = \frac{1}{f'(g(0))} = \frac{1}{f'(0)} = \frac{1}{3(0)^2 + 2} = \boxed{\frac{1}{2}},$$

and

$$g'(3) = \frac{1}{f'(g(3))} = \frac{1}{f'(1)} = \frac{1}{3(1)^2 + 2} = \boxed{\frac{1}{5}}.$$

76. Let $f(x) = 2x^3 + x - 3$. First note that $f(0) = -3$, $f(1) = 0$, and $f'(x) = 6x^2 + 1$. Because g is the inverse function of f , it follows that $g(-3) = 0$, $g(0) = 1$,

$$g'(-3) = \frac{1}{f'(g(-3))} = \frac{1}{f'(0)} = \frac{1}{6(0)^2 + 1} = \frac{1}{1} = \boxed{1},$$

and

$$g'(0) = \frac{1}{f'(g(0))} = \frac{1}{f'(1)} = \frac{1}{6(1)^2 + 1} = \boxed{\frac{1}{7}}.$$

Applications and Extensions

77. Let $y = |3x| = 3|x| = 3\sqrt{x^2}$. Then

$$y' = 3 \cdot \frac{1}{2}(x^2)^{-1/2} \frac{d}{dx} x^2 = \frac{3x}{\sqrt{x^2}} = \boxed{\frac{3x}{|x|}}.$$

78. Let $y = |x^5| = \sqrt{(x^5)^2} = \sqrt{x^{10}}$. Then

$$y' = \frac{1}{2}(x^{10})^{-1/2} \frac{d}{dx} x^{10} = \frac{5x^9}{\sqrt{x^{10}}} = \boxed{\frac{5x^9}{|x^5|}}.$$

79. Let $y = |2x - 1| = \sqrt{(2x - 1)^2}$. Then

$$y' = \frac{1}{2}[(2x - 1)^2]^{-1/2} \frac{d}{dx}(2x - 1)^2 = \frac{2x - 1}{\sqrt{(2x - 1)^2}} \frac{d}{dx}(2x - 1) = \boxed{\frac{2(2x - 1)}{|2x - 1|}}.$$

80. Let $y = |5 - x^2| = \sqrt{(5 - x^2)^2}$. Then

$$y' = \frac{1}{2}[(5 - x^2)^2]^{-1/2} \frac{d}{dx}(5 - x^2)^2 = \frac{5 - x^2}{\sqrt{(5 - x^2)^2}} \frac{d}{dx}(5 - x^2) = \boxed{-\frac{2x(5 - x^2)}{|5 - x^2|}}.$$

81. Let $y = |\cos x| = \sqrt{\cos^2 x}$. Then

$$y' = \frac{1}{2}(\cos^2 x)^{-1/2} \frac{d}{dx} \cos^2 x = \frac{\cos x}{\sqrt{\cos^2 x}} \frac{d}{dx} \cos x = \boxed{-\frac{\cos x \sin x}{|\cos x|}}.$$

82. Let $y = |\sin x| = \sqrt{\sin^2 x}$. Then

$$y' = \frac{1}{2}(\sin^2 x)^{-1/2} \frac{d}{dx} \sin^2 x = \frac{\sin x}{\sqrt{\sin^2 x}} \frac{d}{dx} \sin x = \boxed{\frac{\sin x \cos x}{|\sin x|}}.$$

83. Let $y = \sin |x| = \sin \sqrt{x^2}$. Then

$$y' = \cos \sqrt{x^2} \frac{d}{dx} \sqrt{x^2} = \cos |x| \cdot \frac{1}{2}(x^2)^{-1/2} \frac{d}{dx} x^2 = \cos |x| \cdot \frac{x}{\sqrt{x^2}} = \boxed{\cos |x| \cdot \frac{x}{|x|}}.$$

84. Let $|x| + |y| = 1$ or $\sqrt{x^2} + \sqrt{y^2} = 1$. Then

$$\begin{aligned} \frac{d}{dx}[\sqrt{x^2} + \sqrt{y^2}] &= \frac{d}{dx} 1 \\ \frac{d}{dx} \sqrt{x^2} + \frac{d}{dx} \sqrt{y^2} &= 0 \\ \frac{1}{2}(x^2)^{-1/2} \frac{d}{dx} x^2 + \frac{1}{2}(y^2)^{-1/2} \frac{d}{dx} y^2 &= 0 \\ \frac{x}{\sqrt{x^2}} + \frac{y}{\sqrt{y^2}} \frac{dy}{dx} &= 0 \\ \frac{x}{|x|} + \frac{y}{|y|} \frac{dy}{dx} &= 0 \\ \frac{dy}{dx} &= \boxed{-\frac{x/|x|}{y/|y|}}, \end{aligned}$$

provided $y \neq 0$.

85. Let $x^{2/3} + y^{2/3} = 5$. Then

$$\begin{aligned} \frac{d}{dx}[x^{2/3} + y^{2/3}] &= \frac{d}{dx} 5 \\ \frac{d}{dx} x^{2/3} + \frac{d}{dx} y^{2/3} &= 0 \\ \frac{2}{3} x^{-1/3} + \frac{2}{3} y^{-1/3} \frac{dy}{dx} &= 0 \\ \frac{dy}{dx} &= -\frac{x^{-1/3}}{y^{-1/3}} = -\frac{y^{1/3}}{x^{1/3}}. \end{aligned}$$

The slope of the tangent line to the hypocycloid at the point $(1, 8)$ is therefore

$$m_{\text{tan}} = -\frac{8^{1/3}}{1^{1/3}} = -2,$$

so the equation of the tangent line is

$$y - 8 = -2(x - 1) \quad \text{or} \quad \boxed{y = -2x + 10}.$$

86. The line $x + 16y = 5$ has a slope of $-\frac{1}{16}$, while the slope of the tangent line to the graph of $y = \frac{1}{\sqrt{x}} = x^{-1/2}$ at the point (x, y) is

$$y' = -\frac{1}{2}x^{-3/2}.$$

The tangent line to the graph of $y = \frac{1}{\sqrt{x}}$ will therefore be parallel to the line $x + 16y = 5$ when

$$-\frac{1}{2}x^{-3/2} = -\frac{1}{16} \quad \text{or} \quad x^{3/2} = 8.$$

The solution of this last equation is $x = 4$, so the tangent line to the graph of $y = \frac{1}{\sqrt{x}}$ at the point

$\boxed{\left(4, \frac{1}{2}\right)}$ is parallel to the line $x + 16y = 5$.

87. Let $(x^2 + y^2 + 2x)^2 = 4(x^2 + y^2)$. Then

$$\begin{aligned} \frac{d}{dx}(x^2 + y^2 + 2x)^2 &= \frac{d}{dx}4(x^2 + y^2) \\ 2(x^2 + y^2 + 2x)\frac{d}{dx}(x^2 + y^2 + 2x) &= \frac{d}{dx}(4x^2) + \frac{d}{dx}(4y^2) \\ 2(x^2 + y^2 + 2x)\left(\frac{d}{dx}x^2 + \frac{d}{dx}y^2 + \frac{d}{dx}(2x)\right) &= 8x + 8y\frac{dy}{dx} \\ 2(x^2 + y^2 + 2x)\left(2x + 2y\frac{dy}{dx} + 2\right) &= 8x + 8y\frac{dy}{dx} \\ (x+1)(x^2 + y^2 + 2x) + y(x^2 + y^2 + 2x)\frac{dy}{dx} &= 2x + 2y\frac{dy}{dx} \\ y(x^2 + y^2 + 2x - 2)\frac{dy}{dx} &= 2x - (x+1)(x^2 + y^2 + 2x) \\ \frac{dy}{dx} &= \frac{2x - (x+1)(x^2 + y^2 + 2x)}{y(x^2 + y^2 + 2x - 2)}. \end{aligned}$$

- (a) The graph of the cardioid will have a horizontal tangent line when the numerator of the derivative is equal to zero but the denominator is not equal to zero. Now, $2x - (x+1)(x^2 + y^2 + 2x) = 0$ when $x^2 + y^2 + 2x = \frac{2x}{x+1}$. Substituting $\frac{2x}{x+1}$ for $x^2 + y^2 + 2x$ in the left-hand side of the cardioid equation yields $x^2 + y^2 = \frac{x^2}{(x+1)^2}$. Then,

$$2x = \frac{2x}{x+1} - \frac{x^2}{(x+1)^2} = \frac{2x(x+1) - x^2}{(x+1)^2} = \frac{x^2 + 2x}{(x+1)^2}.$$

Clearing fractions and collecting like terms leads to $2x^3 + 3x^2 = x^2(2x + 3) = 0$, so either $x = 0$ or $x = -\frac{3}{2}$.

- If $x = 0$, the numerator of the derivative reduces to $-y^2$, so y must be 0 for the numerator of the derivative to be 0. However, at the point $(0, 0)$, both the numerator and denominator of the derivative are 0. The tools needed to determine whether or not the derivative exists at the origin have not yet been covered, so we will ignore the origin for now.
- If $x = -\frac{3}{2}$, then

$$\left(-\frac{3}{2}\right)^2 + y^2 = \frac{(-3/2)^2}{(-3/2 + 1)^2} \quad \text{or} \quad y^2 = \frac{27}{4}.$$

Thus, $y = \pm \frac{3\sqrt{3}}{2}$. The denominator of the derivative is not 0 at the points $\left(-\frac{3}{2}, \pm \frac{3\sqrt{3}}{2}\right)$, so the graph of the cardioid has a horizontal tangent line at each.

In summary, the graph of the cardioid has a horizontal tangent line at the two points

$$\boxed{\left(-\frac{3}{2}, \frac{3\sqrt{3}}{2}\right) \quad \text{and} \quad \left(-\frac{3}{2}, -\frac{3\sqrt{3}}{2}\right)}.$$

- (b) The graph of the cardioid will have a vertical tangent line when the denominator of the derivative is equal to zero but the numerator is not equal to zero. Now, $y(x^2 + y^2 + 2x - 2) = 0$ when $y = 0$ or when $x^2 + y^2 + 2x - 2 = 0$.

- If $y = 0$, then the cardioid equation reduces to $(x^2 + 2x)^2 = 4x^2$ or $x^4 + 4x^3 = 0$. Thus, $x = 0$ or $x = -4$. At the point $(0, 0)$, both the numerator and denominator of the derivative are 0. As noted above, the tools needed to determine whether or not the derivative exists at the origin have not yet been covered, so we will ignore the origin for now. At the point $(-4, 0)$, the numerator of the derivative is not zero, so the graph has a vertical tangent line at that point.
- If $x^2 + y^2 + 2x - 2 = 0$, then $x^2 + y^2 + 2x = 2$ and the cardioid equation yields $x^2 + y^2 = 1$. Subtracting $x^2 + y^2 = 1$ from $x^2 + y^2 + 2x = 2$, it follows that $2x = 1$, or $x = \frac{1}{2}$. Substituting this value into $x^2 + y^2 = 1$ then gives $y^2 = \frac{3}{4}$, or $y = \pm \frac{\sqrt{3}}{2}$. When $x^2 + y^2 + 2x = 2$, the numerator of the derivative is equal to -2 , so the graph has a vertical tangent line at both $\left(\frac{1}{2}, \pm \frac{\sqrt{3}}{2}\right)$.

In summary, the graph of the cardioid has a vertical tangent line at the three points

$$\boxed{(-4, 0), \quad \left(\frac{1}{2}, \frac{\sqrt{3}}{2}\right), \quad \text{and} \quad \left(\frac{1}{2}, -\frac{\sqrt{3}}{2}\right)}.$$

88. Let $(x^2 + y^2 + y)^2 = x^2 + y^2$. Then

$$\begin{aligned}
 \frac{d}{dx}(x^2 + y^2 + y)^2 &= \frac{d}{dx}(x^2 + y^2) \\
 2(x^2 + y^2 + y) \frac{d}{dx}(x^2 + y^2 + y) &= \frac{d}{dx}x^2 + \frac{d}{dx}y^2 \\
 2(x^2 + y^2 + y) \left(\frac{d}{dx}x^2 + \frac{d}{dx}y^2 + \frac{dy}{dx} \right) &= 2x + 2y \frac{dy}{dx} \\
 2(x^2 + y^2 + y) \left(2x + (2y + 1) \frac{dy}{dx} \right) &= 2x + 2y \frac{dy}{dx} \\
 2x(x^2 + y^2 + y) + (2y + 1)(x^2 + y^2 + y) \frac{dy}{dx} &= x + y \frac{dy}{dx} \\
 [(2y + 1)(x^2 + y^2 + y) - y] \frac{dy}{dx} &= x[1 - 2(x^2 + y^2 + y)] \\
 \frac{dy}{dx} &= \frac{x[1 - 2(x^2 + y^2 + y)]}{(2y + 1)(x^2 + y^2 + y) - y}.
 \end{aligned}$$

(a) The graph of the cardioid will have a horizontal tangent line when the numerator of the derivative is equal to zero but the denominator is not equal to zero. Now, $x[1 - 2(x^2 + y^2 + y)] = 0$ when $x = 0$ or when $x^2 + y^2 + y = \frac{1}{2}$.

- If $x = 0$, then the cardioid equation reduces to $(y^2 + y)^2 = y^2$, or $y^4 + 2y^2 = 0$. Thus $y = 0$ or $y = -2$. At the point $(0, 0)$, both the numerator and denominator of the derivative are 0. The tools needed to determine whether or not the derivative exists at the origin have not yet been covered, so we will ignore the origin for now. At the point $(0, -2)$, the denominator of the derivative is not zero, so the graph has a horizontal tangent line.
- If $x^2 + y^2 + y = \frac{1}{2}$, then the cardioid equation yields $x^2 + y^2 = \frac{1}{4}$. Subtracting the latter equation from the former, it follows that $y = \frac{1}{4}$. Substituting this value into either of the earlier equations yields $x^2 = \frac{3}{16}$, so that $x = \pm \frac{\sqrt{3}}{4}$. When $x^2 + y^2 + y = \frac{1}{2}$, the denominator of the derivative is equal to $\frac{1}{2}$, so the graph has a horizontal tangent line at both $\left(\pm \frac{\sqrt{3}}{4}, \frac{1}{4}\right)$.

In summary, the graph of the cardioid has a horizontal tangent line at the three points

$$\boxed{(0, -2), \quad \left(\frac{\sqrt{3}}{4}, \frac{1}{4}\right), \quad \text{and} \quad \left(-\frac{\sqrt{3}}{4}, \frac{1}{4}\right)}.$$

(b) The graph of the cardioid will have a vertical tangent line when the denominator of the derivative is equal to zero but the numerator is not equal to zero. Now, $(2y + 1)(x^2 + y^2 + y) - y = 0$ when $x^2 + y^2 + y = \frac{y}{2y + 1}$. Substituting $\frac{y}{2y + 1}$ for $x^2 + y^2 + y$ in the left-hand side of the cardioid equation yields $x^2 + y^2 = \frac{y^2}{(2y + 1)^2}$. Then,

$$y = \frac{y}{2y + 1} - \frac{y^2}{(2y + 1)^2} = \frac{y(2y + 1) - y^2}{(2y + 1)^2} = \frac{y^2 + y}{(2y + 1)^2}.$$

Clearing fractions and collecting like terms leads to $4y^3 + 3y^2 = y^2(4y + 3) = 0$, so either $y = 0$ or $y = -\frac{3}{4}$.

- If $y = 0$, the denominator of the derivative reduces to x^2 , so x must be 0 for the denominator of the derivative to be 0. As noted earlier, both the numerator and denominator of the

derivative are 0 at the point $(0,0)$, and the tools needed to determine whether or not the derivative exists at the origin have not yet been covered, so we will ignore the origin for now.

- If $y = -\frac{3}{4}$, then

$$x^2 + \left(-\frac{3}{4}\right)^2 = \frac{(-3/4)^2}{(-3/2 + 1)^2} \quad \text{or} \quad x^2 = \frac{27}{16}.$$

Thus, $x = \pm \frac{3\sqrt{3}}{4}$. The numerator of the derivative is not 0 at the points $\left(\pm \frac{3\sqrt{3}}{4}, -\frac{3}{4}\right)$, so the graph of the cardioid has a vertical tangent line at each.

In summary, the graph of the cardioid has a vertical tangent line at the two points

$$\left(\frac{3\sqrt{3}}{4}, -\frac{3}{4}\right) \quad \text{and} \quad \left(-\frac{3\sqrt{3}}{4}, -\frac{3}{4}\right).$$

- (c) The figure below displays the graph of the cardioid as the solid curve and the horizontal and vertical tangent lines as dashed curves.

89. (a) Let $x + xy + 2y^2 = 6$. Then

$$\begin{aligned} \frac{d}{dx}[x + xy + 2y^2] &= \frac{d}{dx}6 \\ \frac{d}{dx}x + \frac{d}{dx}(xy) + \frac{d}{dx}(2y^2) &= 0 \\ 1 + x\frac{dy}{dx} + y\frac{d}{dx}x + 4y\frac{dy}{dx} &= 0 \\ 1 + y + (x + 4y)\frac{dy}{dx} &= 0 \\ \frac{dy}{dx} &= \frac{-y-1}{x+4y}. \end{aligned}$$

- (b) The slope of the tangent line to the graph at the point $(2,1)$ is

$$m_{\text{tan}} = -\frac{1+1}{2+4(1)} = -\frac{1}{3},$$

so the equation of the tangent line is

$$y - 1 = -\frac{1}{3}(x - 2) \quad \text{or} \quad y = -\frac{1}{3}x + \frac{5}{3}.$$

(c) Solving

$$-\frac{1+y}{x+4y} = -\frac{1}{3}$$

yields $3+3y = x+4y$ or $x = 3-y$. Substituting this relationship into the equation $x+xy+2y^2 = 6$ then yields

$$3-y+(3-y)y+2y^2 = 6$$

$$3-y+3y-y^2+2y^2 = 6$$

$$y^2+2y-3 = 0$$

$$(y+3)(y-1) = 0.$$

Then, $y = 1$, corresponding to the previously known point $(2, 1)$, or $y = -3$, corresponding to the point $(6, -3)$. The equation of the tangent line at the point $(6, -3)$ is

$$y - (-3) = -\frac{1}{3}(x - 6) \quad \text{or} \quad y = -\frac{1}{3}x - 1.$$

(d) The figure below displays the graph of $x+xy+2y^2 = 6$ as the solid curve and the tangent lines found in parts (b) and (c) as the dashed curves.

90. Let $(x^2 + y^2)^2 = x^2 - y^2$. Then

$$\frac{d}{dx}(x^2 + y^2)^2 = \frac{d}{dx}(x^2 - y^2)$$

$$2(x^2 + y^2) \frac{d}{dx}(x^2 + y^2) = \frac{d}{dx}x^2 - \frac{d}{dx}y^2$$

$$2(x^2 + y^2) \left(\frac{d}{dx}x^2 + \frac{d}{dx}y^2 \right) = 2x - 2y \frac{dy}{dx}$$

$$(x^2 + y^2) \left(2x + 2y \frac{dy}{dx} \right) = x - y \frac{dy}{dx}$$

$$2x(x^2 + y^2) + 2y(x^2 + y^2) \frac{dy}{dx} = x - y \frac{dy}{dx}$$

$$y[2(x^2 + y^2) + 1] \frac{dy}{dx} = x[1 - 2(x^2 + y^2)]$$

$$\frac{dy}{dx} = \frac{x[1 - 2(x^2 + y^2)]}{y[2(x^2 + y^2) + 1]}.$$

The graph of the lemniscate will have a horizontal tangent line when the numerator of the derivative is equal to zero but the denominator is not equal to zero. Now, $x[1 - 2(x^2 + y^2)] = 0$ when $x = 0$ or when $x^2 + y^2 = \frac{1}{2}$.

- If $x = 0$, then the lemniscate equation reduces to $y^4 = -y^2$. The only solution to this equation is $y = 0$. At the point $(0, 0)$, both the numerator and the denominator of the derivative are equal to 0, suggesting that the graph of the lemniscate might not have a horizontal tangent line at the origin. This is confirmed in the graph in the text.
- If $x^2 + y^2 = \frac{1}{2}$, then the lemniscate equation yields $x^2 - y^2 = \frac{1}{4}$. Adding the equations $x^2 + y^2 = \frac{1}{2}$ and $x^2 - y^2 = \frac{1}{4}$, it follows that $2x^2 = \frac{3}{4}$ so that $x = \pm \frac{\sqrt{6}}{4}$. Subtracting the two equations yields $2y^2 = \frac{1}{4}$ so that $y = \pm \frac{\sqrt{2}}{4}$. Also, note that when $x^2 + y^2 = \frac{1}{2}$, the denominator of the derivative is equal to $2y$, which is not 0 for the y -values just calculated.

Thus, the graph of the lemniscate has a horizontal tangent line at the four points

$$\left(\frac{\sqrt{6}}{4}, \frac{\sqrt{2}}{4} \right), \left(-\frac{\sqrt{6}}{4}, \frac{\sqrt{2}}{4} \right), \left(\frac{\sqrt{6}}{4}, -\frac{\sqrt{2}}{4} \right), \text{ and } \left(-\frac{\sqrt{6}}{4}, -\frac{\sqrt{2}}{4} \right).$$

91. (a) Let $y = \sin^{-1} \frac{x}{2}$. Then

$$y' = \frac{1}{\sqrt{1 - (x/2)^2}} \frac{d}{dx} \left(\frac{x}{2} \right) = \frac{2}{\sqrt{4 - x^2}} \cdot \frac{1}{2} = \frac{1}{\sqrt{4 - x^2}}.$$

The slope of the tangent line to the graph at the origin is then

$$m_{\text{tan}} = \frac{1}{\sqrt{4 - 0^2}} = \frac{1}{2},$$

so the equation of the tangent line is

$$y - 0 = \frac{1}{2}(x - 0) \quad \text{or} \quad \boxed{y = \frac{1}{2}x}.$$

- (b) The figure below displays the graph of $y = \sin^{-1} \frac{x}{2}$ as the solid curve, and the graph of the tangent line at the origin as the dashed curve.

92. Let $P + \frac{a}{V^2} = \frac{C}{V-b}$, where C , a , and b are constants. Then

$$\begin{aligned}\frac{d}{dP} \left(P + \frac{a}{V^2} \right) &= \frac{d}{dP} \left(\frac{C}{V-b} \right) \\ \frac{d}{dP} P + \frac{d}{dP} \left(\frac{a}{V^2} \right) &= -\frac{C}{(V-b)^2} \frac{d}{dP} (V-b) \\ 1 - \frac{2a}{V^3} \frac{dV}{dP} &= -\frac{C}{(V-b)^2} \frac{dV}{dP} \\ 1 &= \left(\frac{2a}{V^3} - \frac{C}{(V-b)^2} \right) \frac{dV}{dP} \\ \boxed{\left(\frac{2a}{V^3} - \frac{C}{(V-b)^2} \right)^{-1}} &= \frac{dV}{dP}.\end{aligned}$$

93. Let $m(v^2 - v_0^2) = k(s_0^2 - s^2)$. Then

$$\begin{aligned}\frac{d}{dt}[m(v^2 - v_0^2)] &= \frac{d}{dt}[k(s_0^2 - s^2)] \\ \frac{d}{dt}(mv^2) - \frac{d}{dt}(mv_0^2) &= \frac{d}{dt}ks_0^2 - \frac{d}{dt}(ks^2) \\ 2mv \frac{dv}{dt} - 0 &= 0 - 2ks \frac{ds}{dt} \\ mva &= -ksv \\ ma &= -ks,\end{aligned}$$

where in moving from the next to the last line to the last line, the fact that $v > 0$ was used.

94. (a) Let

$$P(t) = \frac{300}{1 + \frac{1}{6}\sqrt{t}} + 100 = 300 \left(1 + \frac{1}{6}\sqrt{t} \right)^{-1} + 100.$$

Then

$$\begin{aligned}P'(t) &= -300 \left(1 + \frac{1}{6}\sqrt{t} \right)^{-2} \frac{d}{dt} \left(1 + \frac{1}{6}\sqrt{t} \right) = -300 \left(1 + \frac{1}{6}\sqrt{t} \right)^{-2} \frac{1}{12} t^{-1/2} \\ &= \boxed{-\frac{25}{\sqrt{t}} \left(1 + \frac{1}{6}\sqrt{t} \right)^{-2}}.\end{aligned}$$

- (b) Using the result from part (a), $P'(0)$ is undefined,

$$P'(16) = -\frac{25}{\sqrt{16}} \left(1 + \frac{1}{6}\sqrt{16} \right)^{-2} = -\frac{25}{4} \left(\frac{5}{3} \right)^{-2} = -\frac{25}{4} \cdot \frac{9}{25} = -\frac{9}{4} = \boxed{-2.25 \text{ dollars/month}},$$

and

$$P'(49) = -\frac{25}{\sqrt{49}} \left(1 + \frac{1}{6}\sqrt{49} \right)^{-2} = -\frac{25}{7} \left(\frac{13}{6} \right)^{-2} = -\frac{25}{7} \cdot \frac{36}{169} = -\frac{900}{1183} \approx \boxed{-0.76 \text{ dollars/month}}.$$

Thus, 16 months from now, the price of a tablet will be decreasing at the rate of \$2.25 per month, while 49 months from now, the price of a tablet will be decreasing at the rate of \$0.76 per month.

- (c) The figure below displays the graph of $P'(t)$. The graph appears to have a vertical asymptote at $t = 0$ and is always negative but increasing. This supports the answers in part (b), where it was found that $P'(49)$ was greater than $P'(16)$.

95. Let $z = x^{0.5}y^{0.4}$ and suppose z is held constant. Then

$$\begin{aligned}
 \frac{d}{dx}z &= \frac{d}{dx}[x^{0.5}y^{0.4}] \\
 0 &= x^{0.5}\frac{d}{dx}y^{0.4} + y^{0.4}\frac{d}{dx}x^{0.5} \\
 0 &= 0.4x^{0.5}y^{-0.6}\frac{dy}{dx} + 0.5y^{0.4}x^{-0.5} \\
 -0.4x^{0.5}y^{-0.6}\frac{dy}{dx} &= 0.5y^{0.4}x^{-0.5} \\
 \frac{dy}{dx} &= -\frac{0.5y^{0.4}x^{-0.5}}{0.4x^{0.5}y^{-0.6}} = -\frac{5y}{4x}.
 \end{aligned}$$

96. (a) Let $T = f(n) = Cn\sqrt{n-b}$, where C and b are constants. Then the rate of change in time with respect to the number of words to be memorized is

$$\begin{aligned}
 f'(n) &= \frac{d}{dn}[Cn\sqrt{n-b}] = Cn\frac{d}{dn}\sqrt{n-b} + \sqrt{n-b}\frac{d}{dn}(Cn) \\
 &= \frac{1}{2}Cn(n-b)^{-1/2}\frac{d}{dn}(n-b) + C\sqrt{n-b} \\
 &= \boxed{\frac{Cn}{2\sqrt{n-b}} + C\sqrt{n-b}}.
 \end{aligned}$$

(b) Let $C = 2$ and $b = 2$. Then

$$f'(10) = \frac{2(10)}{2\sqrt{10-2}} + 2\sqrt{10-2} = \frac{10}{\sqrt{8}} + 2\sqrt{8} = \frac{13\sqrt{2}}{2} \approx \boxed{9.2 \text{ minutes/word}}$$

and

$$f'(30) = \frac{2(30)}{2\sqrt{30-2}} + 2\sqrt{30-2} = \frac{30}{\sqrt{28}} + 2\sqrt{28} = \frac{43\sqrt{7}}{7} \approx \boxed{16.3 \text{ minutes/word}}.$$

(c) Answers will vary. One possible response is that $f'(30) > f'(10)$ implies it takes more time to memorize an additional word added to a longer list of words than it does to memorize an additional word added to a shorter list of words.

97. (a) Let $x^3 + y^3 = 2xy$. Then

$$\begin{aligned}\frac{d}{dx}[x^3 + y^3] &= \frac{d}{dx}(2xy) \\ \frac{d}{dx}x^3 + \frac{d}{dx}y^3 &= 2x\frac{dy}{dx} + y\frac{d}{dx}(2x) \\ 3x^2 + 3y^2\frac{dy}{dx} &= 2x\frac{dy}{dx} + 2y \\ (3y^2 - 2x)\frac{dy}{dx} &= 2y - 3x^2 \\ y' = \frac{dy}{dx} &= \frac{2y - 3x^2}{3y^2 - 2x} = \boxed{\frac{3x^2 - 2y}{2x - 3y^2}}.\end{aligned}$$

- (b) The slope of the line tangent to the graph at the point $(1, 1)$ is

$$m_{\tan} = \frac{2(1) - 3(1)^2}{3(1)^2 - 2(1)} = \frac{-1}{1} = -1,$$

so the equation of the tangent line is

$$y - 1 = -1(x - 1) \quad \text{or} \quad \boxed{y = -x + 2}.$$

- (c) The tangent line to the graph of the Folium of Descartes will be horizontal when the numerator of the derivative is equal to zero but the denominator is not equal to zero. Now, $2y - 3x^2 = 0$ when $y = \frac{3}{2}x^2$. Substituting this expression into the equation for the Folium of Descartes yields

$$x^3 + \frac{27}{8}x^6 = 3x^3 \quad \text{or} \quad x^3 \left(\frac{27}{8}x^3 - 2 \right) = 0.$$

Thus, $x^3 = 0$ or $x^3 = \frac{16}{27}$, and finally, $x = 0$ or $x = \left(\frac{16}{27}\right)^{1/3} = \frac{2^{4/3}}{3}$.

- If $x = 0$, then $y = \frac{3}{2}x^2 = 0$. At the point $(0,0)$, both the numerator and the denominator of the derivative are equal to 0. The tools needed to determine whether or not the derivative exists at the origin have not yet been covered, so we will ignore the origin for now.
- If $x = \frac{2^{4/3}}{3}$, then $y = \frac{3}{2}x^2 = \frac{3}{2}\left(\frac{2^{4/3}}{3}\right)^2 = \frac{2^{5/3}}{3}$. The denominator of the derivative is not

zero at the point $\left(\frac{2^{4/3}}{3}, \frac{2^{5/3}}{3}\right)$, so the Folium of Descartes has a horizontal tangent line at this point.

- (d) The figure below displays the graph of the Folium of Descartes as the solid curve and the tangent lines from parts (b) and (c) as dashed curves.

98. Let n be an even positive integer. Then the slope of the tangent line to the graph of $y = \sqrt[n]{x}$ at the point $(1, 1)$ is

$$y'(1) = \frac{1}{n}(1)^{1/n-1} = \frac{1}{n},$$

while the slope of the tangent line to the graph of $y = x^n$ at the point $(-1, 1)$ is

$$y'(-1) = n(-1)^{n-1} = -n.$$

Because these slopes are negative reciprocals of one another, the two lines are perpendicular.

99. Let $y = \sqrt{25 - x^2}$. Then

$$y' = \frac{1}{2}(25 - x^2)^{-1/2} \frac{d}{dx}(25 - x^2) = \frac{1}{2\sqrt{25 - x^2}} \cdot (-2x) = -\frac{x}{\sqrt{25 - x^2}}.$$

The tangent line to the graph of $y = \sqrt{25 - x^2}$ at the point (x_0, y_0) has slope

$$m_{\text{tan}} = -\frac{x_0}{\sqrt{25 - x_0^2}}.$$

For the tangent line to be parallel to the line $y = x - 1$, the slope of the tangent line must equal 1. Solving the equation

$$-\frac{x_0}{\sqrt{25 - x_0^2}} = 1$$

yields

$$-x_0 = \sqrt{25 - x_0^2} \quad \text{so that} \quad x_0^2 = 25 - x_0^2 \quad \text{and} \quad x_0 = \pm \frac{5\sqrt{2}}{2}.$$

The positive value for x_0 is extraneous because the slope of the tangent line at this location is -1 , so the only point on the graph of $y = \sqrt{25 - x^2}$ at which the tangent line is parallel to the line $y = x - 1$ is

$$\left(-\frac{5\sqrt{2}}{2}, \frac{5\sqrt{2}}{2} \right).$$

100. Consider the equation $x + y = e^{x+y}$. The implicit differentiation calculations, and the conclusions drawn from them, that are presented in the problem statement hold for all points (x, y) whose coordinates satisfy the original implicit equation. So, let's suppose the coordinates of the point (x, y) satisfy the equation $x + y = e^{x+y}$. Further, suppose that $x + y = c$ for some real number c . Then, $c = e^c$. Now, consider the figure below, which displays the graphs of the function $f(c) = e^c$ (the solid curve) and $g(c) = c$ (the dashed curve). The two graphs do not intersect, which means that there is no real number c such that $f(c) = g(c)$, or $e^c = c$. Thus, the equation $x + y = e^{x+y}$ is not satisfied by any ordered pair (x, y) .

101. Let $x^n y^m + x^m y^n = k$, where k , m , and n are constants. Then

$$\begin{aligned}\frac{d}{dx}(x^n y^m + x^m y^n) &= \frac{d}{dx}k \\ \frac{d}{dx}(x^n y^m) + \frac{d}{dx}(x^m y^n) &= 0 \\ x^n \frac{d}{dx}y^m + y^m \frac{d}{dx}x^n + x^m \frac{d}{dx}y^n + y^n \frac{d}{dx}x^m &= 0 \\ mx^n y^{m-1} \frac{dy}{dx} + nx^{n-1} y^m + nx^m y^{n-1} \frac{dy}{dx} + mx^{m-1} y^n &= 0,\end{aligned}$$

so that

$$(mx^n y^{m-1} + nx^m y^{n-1}) \frac{dy}{dx} = -(nx^{n-1} y^m + mx^{m-1} y^n)$$

and

$$\begin{aligned}\frac{dy}{dx} &= -\frac{nx^{n-1} y^m + mx^{m-1} y^n}{mx^n y^{m-1} + nx^m y^{n-1}} \cdot \frac{xy}{xy} \\ &= -\frac{y(nx^n y^m + mx^m y^n)}{x(mx^n y^m + nx^m y^n)} = -\frac{x^m y^m \cdot y(nx^{n-m} + my^{n-m})}{x^m y^m \cdot x(mx^{n-m} + ny^{n-m})} \\ &= -\frac{y(nx^{n-m} + my^{n-m})}{x(mx^{n-m} + ny^{n-m})} = -\frac{y(nx^r + my^r)}{x(mx^r + ny^r)},\end{aligned}$$

where $r = n - m$.

102. Let $g(x) = \cos^{-1}(\cos x)$. Then

$$g'(x) = -\frac{1}{\sqrt{1 - \cos^2 x}} \frac{d}{dx} \cos x = -\frac{1}{\sqrt{\sin^2 x}} \cdot (-\sin x) = \frac{\sin x}{|\sin x|}.$$

103. $\frac{d}{dx} \tan^{-1}(\cot x) = \frac{1}{1 + \cot^2 x} \frac{d}{dx} \cot x = \frac{1}{\csc^2 x} \cdot (-\csc^2 x) = -1$.

104. For all real numbers x ,

$$\frac{d}{dx} \cot^{-1} x = -\frac{1}{1 + x^2},$$

while for $x \neq 0$,

$$\frac{d}{dx} \tan^{-1} \frac{1}{x} = \frac{1}{1 + (1/x)^2} \frac{d}{dx} \left(\frac{1}{x} \right) = \frac{x^2}{1 + x^2} \cdot \left(-\frac{1}{x^2} \right) = -\frac{1}{1 + x^2}.$$

Thus, for all $x \neq 0$,

$$\frac{d}{dx} \cot^{-1} x = \frac{d}{dx} \tan^{-1} \frac{1}{x}.$$

105. Let $y = \sin^{-1} x + \cos^{-1} x$. Then

$$y' = \frac{1}{\sqrt{1 - x^2}} - \frac{1}{\sqrt{1 - x^2}} = 0.$$

Thus, $y(x)$ is a constant function. Because

$$y(0) = \sin^{-1} 0 + \cos^{-1} 0 = 0 + \frac{\pi}{2} = \frac{\pi}{2},$$

it follows that

$$\sin^{-1} x + \cos^{-1} x = \frac{\pi}{2}.$$

106. Let $y = \tan^{-1} x + \cot^{-1} x$. Then

$$y' = \frac{1}{1+x^2} - \frac{1}{1+x^2} = 0.$$

Thus, $y(x)$ is a constant function. Because

$$y(1) = \tan^{-1} 1 + \cot^{-1} 1 = \frac{\pi}{4} + \frac{\pi}{4} = \frac{\pi}{2},$$

it follows that

$$\tan^{-1} x + \cot^{-1} x = \frac{\pi}{2}.$$

107. Consider the equation $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$. Then

$$\begin{aligned} \frac{d}{dx} \left(\frac{x^2}{a^2} + \frac{y^2}{b^2} \right) &= \frac{d}{dx} 1 \\ \frac{d}{dx} \left(\frac{x^2}{a^2} \right) + \frac{d}{dx} \left(\frac{y^2}{b^2} \right) &= 0 \\ \frac{2x}{a^2} + \frac{2y}{b^2} \frac{dy}{dx} &= 0 \\ \frac{dy}{dx} &= -\frac{b^2 x}{a^2 y}. \end{aligned}$$

The slope of the tangent line to the graph of the ellipse at (x_0, y_0) is then

$$m_{\tan} = -\frac{b^2 x_0}{a^2 y_0},$$

so the equation of the tangent line is

$$y - y_0 = -\frac{b^2 x_0}{a^2 y_0}(x - x_0) \quad \text{or} \quad b^2 x x_0 + a^2 y y_0 = b^2 x_0^2 + a^2 y_0^2.$$

Dividing by $a^2 b^2$ then yields

$$\frac{x x_0}{a^2} + \frac{y y_0}{b^2} = \frac{x_0^2}{a^2} + \frac{y_0^2}{b^2} = 1,$$

because (x_0, y_0) is a point on the graph of the ellipse.

108. Let $x^{2/3} + y^{2/3} = a^{2/3}$, where $a > 0$ is a constant. Then

$$\begin{aligned} \frac{d}{dx}(x^{2/3} + y^{2/3}) &= \frac{d}{dx} a^{2/3} \\ \frac{2}{3} x^{-1/3} + \frac{2}{3} y^{-1/3} \frac{dy}{dx} &= 0 \\ \frac{dy}{dx} &= -\frac{x^{-1/3}}{y^{-1/3}} = -\frac{y^{1/3}}{x^{1/3}}. \end{aligned}$$

Thus, the slope of the tangent line to the graph of a hypocycloid is $-\frac{y^{1/3}}{x^{1/3}}$ at any point for which $x \neq 0$.

109. Let $P = (x_0, y_0)$ be a point on the circle $x^2 + y^2 = R^2$ with $x_0 \neq 0$ and $y_0 \neq 0$. The slope of the segment $\overline{OP}$, where O is the center of the circle, is y_0/x_0 . Applying implicit differentiation to the

equation of the circle yields

$$\begin{aligned}\frac{d}{dx}(x^2 + y^2) &= \frac{d}{dx}R^2 \\ \frac{d}{dx}x^2 + \frac{d}{dx}y^2 &= 0 \\ 2x + 2y\frac{dy}{dx} &= 0 \\ \frac{dy}{dx} &= -\frac{x}{y}.\end{aligned}$$

The slope of the tangent line to the graph of the circle at the point $P = (x_0, y_0)$ is then

$$m_{\text{tan}} = -\frac{x_0}{y_0}.$$

The slope of the segment $\overline{OP}$ and the slope of the tangent line are negative reciprocals of one another, which means that the segment $\overline{OP}$ and the tangent line are perpendicular.

Now, what if $x_0 = 0$ or $y_0 = 0$. If $x_0 = 0$, then $y_0 = \pm R$. The segment $\overline{OP}$ is vertical while the tangent line is horizontal, so the segment $\overline{OP}$ and the tangent line are perpendicular. On the other hand, if $y_0 = 0$, then $x_0 = \pm R$. The segment $\overline{OP}$ is now horizontal while the tangent line is vertical, so the segment $\overline{OP}$ and the tangent line are again perpendicular.

Challenge Problems

110. As the line parallel to the secant line containing points A and B is moved upward, it will last touch the graph of f when it coincides with a tangent line. Because the secant line through points A and B has slope

$$m_{\text{sec}} = \frac{2-1}{5-2} = \frac{1}{3},$$

the tangent line must also have this slope. Therefore the x -coordinate of the last point on the graph of f before the secant loses contact with the graph must satisfy

$$f'(x) = \frac{1}{2}(x-1)^{-1/2} \frac{d}{dx}(x-1) = \frac{1}{2\sqrt{x-1}} = \frac{1}{3}.$$

Solving this equation for x yields

$$\sqrt{x-1} = \frac{3}{2} \quad \text{so that} \quad x = \frac{9}{4} + 1 = \frac{13}{4}.$$

The y -coordinate of the required point is then

$$f\left(\frac{13}{4}\right) = \sqrt{\frac{13}{4} - 1} = \sqrt{\frac{9}{4}} = \frac{3}{2}.$$

Thus, the last point on the graph of f before the line parallel to the secant line AB loses contact with the graph of f is

$$\boxed{\left(\frac{13}{4}, \frac{3}{2}\right)}.$$

111. (a) For the curve $xy = c_1$, implicit differentiation yields

$$x\frac{dy}{dx} + y = 0 \quad \text{or} \quad \frac{dy}{dx} = -\frac{y}{x};$$

for the curve $-x^2 + y^2 = c_2$, implicit differentiation yields

$$-2x + 2y \frac{dy}{dx} = 0 \quad \text{or} \quad \frac{dy}{dx} = \frac{x}{y}.$$

Suppose the point (x_0, y_0) lies on both curves. At this point, the slope of the tangent line to the curve $xy = c_1$ is $-y_0/x_0$, while the slope of the tangent line to the curve $-x^2 + y^2 = c_2$ is x_0/y_0 . Because these slopes are negative reciprocals of one another, the two tangent lines are perpendicular. Therefore, the graphs of $xy = c_1$ and $-x^2 + y^2 = c_2$ are orthogonal.

- (b) The figure below displays the graphs of $xy = c_1$ with $c_1 = 1, 2$, and 3 as the solid curves and the graphs of $-x^2 + y^2 = c_2$ with $c_2 = 1, 9$, and 25 as the dashed curves. The value of both c_1 and c_2 increase as the graph moves further from the origin.

112. The parabolas $y^2 = 2ax + a^2$ and $y^2 = a^2 - 2ax$ intersect when

$$2ax + a^2 = a^2 - 2ax \quad \text{or when} \quad x = 0.$$

Substituting $x = 0$ into either parabola equation yields $y^2 = a^2$, so that $y = \pm a$. Therefore, the parabolas $y^2 = 2ax + a^2$ and $y^2 = a^2 - 2ax$ intersect at the points $(0, \pm a)$. For the parabola $y^2 = 2ax + a^2$, implicit differentiation yields

$$2y \frac{dy}{dx} = 2a \quad \text{or} \quad \frac{dy}{dx} = \frac{a}{y};$$

for the parabola $y^2 = a^2 - 2ax$, implicit differentiation yields

$$2y \frac{dy}{dx} = -2a \quad \text{or} \quad \frac{dy}{dx} = -\frac{a}{y}.$$

At the point $(0, a)$, the slopes of the tangent lines to the two parabolas are 1 and -1 , respectively, while at the point $(0, -a)$, the slopes of the tangent lines to the two parabolas are -1 and 1, respectively. These slopes are negative reciprocals of one another for any $a > 0$, so the graphs of the two parabolas $y^2 = 2ax + a^2$ and $y^2 = a^2 - 2ax$ are orthogonal for any $\boxed{a > 0}$.

113. Let p and $q > 0$ be integers. The functions $f(x) = x^p$ and $g(x) = x^{1/q} = \sqrt[q]{x}$ are differentiable on their domains, so the composite function $h(x) = f(g(x)) = (x^{1/q})^p = x^{p/q}$ is also differentiable on its domain.

114. Let y be an algebraic function of x and suppose

$$P_0(x)y^n + P_1(x)y^{n-1} + \cdots + P_{n-1}(x)y + P_n(x) = 0.$$

By implicit differentiation,

$$P_0(x) \cdot ny^{n-1}y' + y^n P_0'(x) + P_1(x) \cdot (n-1)y^{n-2}y' + y^{n-1}P_1'(x) + \cdots \\ + P_{n-1}(x) \cdot y' + yP_{n-1}'(x) + P_n'(x) = 0,$$

or

$$y' = -\frac{y^n P_0'(x) + y^{n-1}P_1'(x) + \cdots + yP_{n-1}'(x) + P_n'(x)}{nP_0(x)y^{n-1} + (n-1)P_1(x)y^{n-2} + \cdots + P_{n-1}(x)}.$$

115. Note that $x^{p/q} = (x^{1/q})^p$. Therefore,

$$\begin{aligned} \frac{d}{dx}x^{p/q} &= p(x^{1/q})^{p-1} \cdot \frac{d}{dx}x^{1/q} = p(x^{1/q})^{p-1} \cdot \frac{1}{q}x^{(1/q)-1} \\ &= \frac{p}{q}x^{(p/q)-(1/q)+(1/q)-1} = \frac{p}{q}x^{(p/q)-1}. \end{aligned}$$

116. (a) Let $y = \cot^{-1}x - \tan^{-1}\frac{1}{x}$. By Problem 104,

$$\frac{dy}{dx} = \frac{d}{dx}\cot^{-1}x - \frac{d}{dx}\tan^{-1}\frac{1}{x} = 0$$

for all $x \neq 0$. Thus, on the intervals $(-\infty, 0)$ and $(0, \infty)$, $y = \cot^{-1}x - \tan^{-1}\frac{1}{x}$ must be a constant function, but the constants can be different on the two intervals. For $x = -1$,

$$y = \cot^{-1}(-1) - \tan^{-1}(-1) = \frac{3\pi}{4} - \left(-\frac{\pi}{4}\right) = \pi,$$

while for $x = 1$,

$$y = \cot^{-1}1 - \tan^{-1}1 = \frac{\pi}{4} - \frac{\pi}{4} = 0.$$

Thus,

$$\cot^{-1}x = \begin{cases} \tan^{-1}\frac{1}{x}, & x > 0 \\ \tan^{-1}\frac{1}{x} + \pi, & x < 0. \end{cases}$$

(b) The function $y = \cot^{-1}x - \tan^{-1}\frac{1}{x}$ is discontinuous at $x = 0$.

3.3: Derivatives of Logarithmic Functions

Concepts and Vocabulary

1. $\frac{d}{dx} \ln x = \boxed{\frac{1}{x}}$ for $x > 0$.
2. $\boxed{\text{True}}$. $\frac{d}{dx} x^e = ex^{e-1}$ because e is a constant so x^e is a power function.
3. $\boxed{\text{False}}$. $\frac{d}{dx} \ln[x \sin^2 x] = \frac{d}{dx} \ln x + \frac{d}{dx} \ln \sin^2 x$.
4. $\boxed{\text{False}}$. $\frac{d}{dx} \ln \pi = 0$ because $\ln \pi$ is a constant.
5. $\frac{d}{dx} \ln |x| = \boxed{\frac{1}{x}}$ for all $x \neq 0$.
6. $\lim_{n \rightarrow \infty} \left(1 + \frac{1}{n}\right)^n = \boxed{e}$.

Skill Building

7. Let $y = 5 \ln x$. Then $y' = \boxed{\frac{5}{x}}$.
8. Let $y = -3 \ln x$. Then $y' = \boxed{-\frac{3}{x}}$.
9. Let $y = \log_2 u$. Then $y' = \boxed{\frac{1}{u \ln 2}}$.
10. Let $y = \log_3 u$. Then $y' = \boxed{\frac{1}{u \ln 3}}$.
11. Let $y = (\cos x)(\ln x)$. Then

$$y' = \cos x \frac{d}{dx} \ln x + \ln x \frac{d}{dx} \cos x = \boxed{\frac{1}{x} \cos x - (\sin x)(\ln x)}.$$
12. Let $y = (\sin x)(\ln x)$. Then

$$y' = \sin x \frac{d}{dx} \ln x + \ln x \frac{d}{dx} \sin x = \boxed{\frac{1}{x} \sin x + (\cos x)(\ln x)}.$$
13. Let $y = \ln(3x)$. Then $y' = \frac{1}{3x} \frac{d}{dx}(3x) = \frac{3}{3x} = \boxed{\frac{1}{x}}$.
14. Let $y = \ln \frac{x}{2}$. Then $y' = \frac{2}{x} \frac{d}{dx} \left(\frac{x}{2}\right) = \frac{2}{2x} = \boxed{\frac{1}{x}}$.
15. Let $y = \ln(e^t - e^{-t})$. Then

$$\begin{aligned} y' &= \frac{1}{e^t - e^{-t}} \frac{d}{dt}(e^t - e^{-t}) = \frac{1}{e^t - e^{-t}} \left(\frac{d}{dt} e^t - \frac{d}{dt} e^{-t} \right) \\ &= \frac{1}{e^t - e^{-t}} \left(e^t - e^{-t} \frac{d}{dt}(-t) \right) = \boxed{\frac{e^t + e^{-t}}{e^t - e^{-t}}}. \end{aligned}$$

16. Let $y = \ln(e^{at} + e^{-at})$. Then

$$\begin{aligned} y' &= \frac{1}{e^{at} + e^{-at}} \frac{d}{dt}(e^{at} + e^{-at}) = \frac{1}{e^{at} + e^{-at}} \left(\frac{d}{dt}e^{at} + \frac{d}{dt}e^{-at} \right) \\ &= \frac{1}{e^{at} + e^{-at}} \left(e^{at} \frac{d}{dt}(at) + e^{-at} \frac{d}{dt}(-at) \right) = \boxed{\frac{ae^{at} - ae^{-at}}{e^{at} + e^{-at}}}. \end{aligned}$$

17. Let $y = x \ln(x^2 + 4)$. Then

$$\begin{aligned} y' &= x \frac{d}{dx} \ln(x^2 + 4) + \ln(x^2 + 4) \frac{d}{dx} x = x \cdot \frac{1}{x^2 + 4} \frac{d}{dx}(x^2 + 4) + \ln(x^2 + 4) \\ &= \frac{x}{x^2 + 4} \cdot 2x + \ln(x^2 + 4) = \boxed{\frac{2x^2}{x^2 + 4} + \ln(x^2 + 4)}. \end{aligned}$$

18. Let $y = x \ln(x^2 + 5x + 1)$. Then

$$\begin{aligned} y' &= x \frac{d}{dx} \ln(x^2 + 5x + 1) + \ln(x^2 + 5x + 1) \frac{d}{dx} x \\ &= x \cdot \frac{1}{x^2 + 5x + 1} \frac{d}{dx}(x^2 + 5x + 1) + \ln(x^2 + 5x + 1) \\ &= \frac{x}{x^2 + 5x + 1} \cdot (2x + 5) + \ln(x^2 + 5x + 1) = \boxed{\frac{2x^2 + 5x}{x^2 + 5x + 1} + \ln(x^2 + 5x + 1)}. \end{aligned}$$

19. Let $y = v \ln \sqrt{v^2 + 1} = \frac{1}{2} v \ln(v^2 + 1)$. Then

$$\begin{aligned} y' &= \frac{1}{2} v \frac{d}{dv} \ln(v^2 + 1) + \ln(v^2 + 1) \frac{d}{dv} \left(\frac{1}{2} v \right) = \frac{1}{2} v \cdot \frac{1}{v^2 + 1} \frac{d}{dv}(v^2 + 1) + \frac{1}{2} \ln(v^2 + 1) \\ &= \frac{v}{2(v^2 + 1)} \cdot 2v + \ln \sqrt{v^2 + 1} = \boxed{\frac{v^2}{v^2 + 1} + \ln \sqrt{v^2 + 1}}. \end{aligned}$$

20. Let $y = v \ln \sqrt[3]{3v + 1} = \frac{1}{3} v \ln(3v + 1)$. Then

$$\begin{aligned} y' &= \frac{1}{3} v \frac{d}{dv} \ln(3v + 1) + \ln(3v + 1) \frac{d}{dv} \left(\frac{1}{3} v \right) = \frac{1}{3} v \cdot \frac{1}{3v + 1} \frac{d}{dv}(3v + 1) + \frac{1}{3} \ln(3v + 1) \\ &= \frac{v}{3(3v + 1)} \cdot 3 + \ln \sqrt[3]{3v + 1} = \boxed{\frac{v}{3v + 1} + \ln \sqrt[3]{3v + 1}}. \end{aligned}$$

21. Let $y = \frac{1}{2} \ln \frac{1+x}{1-x} = \frac{1}{2} (\ln(1+x) - \ln(1-x))$. Then

$$\begin{aligned} y' &= \frac{1}{2} \left(\frac{1}{1+x} \frac{d}{dx}(1+x) - \frac{1}{1-x} \frac{d}{dx}(1-x) \right) = \frac{1}{2} \left(\frac{1}{1+x} + \frac{1}{1-x} \right) \\ &= \frac{1}{2} \cdot \frac{(1-x) + (1+x)}{1-x^2} = \frac{1}{2} \cdot \frac{2}{1-x^2} = \boxed{\frac{1}{1-x^2}}. \end{aligned}$$

22. Let $y = \frac{1}{2} \ln \frac{1+x^2}{1-x^2} = \frac{1}{2} (\ln(1+x^2) - \ln(1-x^2))$. Then

$$\begin{aligned} y' &= \frac{1}{2} \left(\frac{1}{1+x^2} \frac{d}{dx}(1+x^2) - \frac{1}{1-x^2} \frac{d}{dx}(1-x^2) \right) = \frac{1}{2} \left(\frac{2x}{1+x^2} + \frac{2x}{1-x^2} \right) \\ &= x \cdot \frac{(1-x^2) + (1+x^2)}{1-x^4} = \boxed{\frac{2x}{1-x^4}}. \end{aligned}$$

23. Let $y = \ln(\ln x)$. Then $y' = \frac{1}{\ln x} \frac{d}{dx} \ln x = \boxed{\frac{1}{x \ln x}}$.

24. Let $y = \ln\left(\ln \frac{1}{x}\right) = \ln(-\ln x)$. Then

$$y' = \frac{1}{-\ln x} \frac{d}{dx} (-\ln x) = \boxed{\frac{1}{x \ln x}}.$$

25. Let $y = \ln \frac{x}{\sqrt{x^2+1}} = \ln x - \ln \sqrt{x^2+1} = \ln x - \frac{1}{2} \ln(x^2+1)$. Then

$$y' = \frac{1}{x} - \frac{1}{2} \cdot \frac{1}{x^2+1} \frac{d}{dx} (x^2+1) = \frac{1}{x} - \frac{1}{2(x^2+1)} \cdot 2x = \frac{1}{x} - \frac{x}{x^2+1} = \boxed{\frac{1}{x(x^2+1)}}.$$

26. Let $y = \ln \frac{4x^3}{\sqrt{x^2+4}} = \ln 4 + \ln x^3 - \ln \sqrt{x^2+4} = \ln 4 + 3 \ln x - \frac{1}{2} \ln(x^2+4)$. Then

$$y' = 0 + \frac{3}{x} - \frac{1}{2} \cdot \frac{1}{x^2+4} \frac{d}{dx} (x^2+4) = \frac{3}{x} - \frac{1}{2(x^2+4)} \cdot 2x = \boxed{\frac{3}{x} - \frac{x}{x^2+4}}.$$

27. Let

$$y = \ln \frac{(x^2+1)^2}{x\sqrt{x^2-1}} = \ln(x^2+1)^2 - \ln x - \ln \sqrt{x^2-1} = 2 \ln(x^2+1) - \ln x - \frac{1}{2} \ln(x^2-1).$$

Then

$$y' = \frac{2}{x^2+1} \frac{d}{dx} (x^2+1) - \frac{1}{x} - \frac{1}{2(x^2-1)} \frac{d}{dx} (x^2-1) = \boxed{\frac{4x}{x^2+1} - \frac{1}{x} - \frac{x}{x^2-1}}.$$

28. Let

$$y = \ln \frac{x\sqrt{3x-1}}{(x^2+1)^3} = \ln x + \ln \sqrt{3x-1} - \ln(x^2+1)^3 = \ln x + \frac{1}{2} \ln(3x-1) - 3 \ln(x^2+1).$$

Then

$$y' = \frac{1}{x} + \frac{1}{2(3x-1)} \frac{d}{dx} (3x-1) - \frac{3}{x^2+1} \frac{d}{dx} (x^2+1) = \boxed{\frac{1}{x} + \frac{3}{2(3x-1)} - \frac{6x}{x^2+1}}.$$

29. Let $y = \ln(\sin \theta)$. Then $y' = \frac{1}{\sin \theta} \frac{d}{d\theta} \sin \theta = \frac{\cos \theta}{\sin \theta} = \boxed{\cot \theta}$.

30. Let $y = \ln(\cos \theta)$. Then $y' = \frac{1}{\cos \theta} \frac{d}{d\theta} \cos \theta = -\frac{\sin \theta}{\cos \theta} = \boxed{-\tan \theta}$.

31. Let $y = \ln(x + \sqrt{x^2+4})$. Then

$$\begin{aligned} y' &= \frac{1}{x + \sqrt{x^2+4}} \frac{d}{dx} (x + \sqrt{x^2+4}) = \frac{1}{x + \sqrt{x^2+4}} \left(1 + \frac{1}{2}(x^2+4)^{-1/2} \frac{d}{dx} (x^2+4) \right) \\ &= \frac{1}{x + \sqrt{x^2+4}} \left(1 + \frac{1}{2\sqrt{x^2+4}} \cdot 2x \right) = \frac{1}{x + \sqrt{x^2+4}} \left(1 + \frac{x}{\sqrt{x^2+4}} \right) \\ &= \frac{1}{x + \sqrt{x^2+4}} \cdot \frac{x + \sqrt{x^2+4}}{\sqrt{x^2+4}} = \boxed{\frac{1}{\sqrt{x^2+4}}}. \end{aligned}$$

32. Let $y = \ln(\sqrt{x+1} + \sqrt{x})$. Then

$$\begin{aligned} y' &= \frac{1}{\sqrt{x+1} + \sqrt{x}} \frac{d}{dx}(\sqrt{x+1} + \sqrt{x}) = \frac{1}{\sqrt{x+1} + \sqrt{x}} \left(\frac{1}{2}(x+1)^{-1/2} \frac{d}{dx}(x+1) + \frac{1}{2}x^{-1/2} \right) \\ &= \frac{1}{\sqrt{x+1} + \sqrt{x}} \left(\frac{1}{2\sqrt{x+1}} + \frac{1}{2\sqrt{x}} \right) = \frac{1}{\sqrt{x+1} + \sqrt{x}} \cdot \frac{\sqrt{x+1} + \sqrt{x}}{2\sqrt{x+1}\sqrt{x}} \\ &= \boxed{\frac{1}{2\sqrt{x+1}\sqrt{x}}}. \end{aligned}$$

33. Let $y = \log_2(1+x^2)$. Then $y' = \frac{1}{(1+x^2)\ln 2} \frac{d}{dx}(1+x^2) = \boxed{\frac{2x}{(1+x^2)\ln 2}}$.

34. Let $y = \log_2(x^2-1)$. Then $y' = \frac{1}{(x^2-1)\ln 2} \frac{d}{dx}(x^2-1) = \boxed{\frac{2x}{(x^2-1)\ln 2}}$.

35. Let $y = \tan^{-1}(\ln x)$. Then $y' = \frac{1}{1+(\ln x)^2} \frac{d}{dx} \ln x = \boxed{\frac{1}{x(1+(\ln x)^2)}}$.

36. Let $y = \sin^{-1}(\ln x)$. Then $y' = \frac{1}{\sqrt{1-(\ln x)^2}} \frac{d}{dx} \ln x = \boxed{\frac{1}{x\sqrt{1-(\ln x)^2}}}$.

37. Let $y = \ln(\tan^{-1} t)$. Then $y' = \frac{1}{\tan^{-1} t} \frac{d}{dt} \tan^{-1} t = \boxed{\frac{1}{\tan^{-1} t} \cdot \frac{1}{1+t^2}}$.

38. Let $y = \ln(\sin^{-1} t)$. Then $y' = \frac{1}{\sin^{-1} t} \frac{d}{dt} \sin^{-1} t = \boxed{\frac{1}{\sin^{-1} t} \cdot \frac{1}{\sqrt{1-t^2}}}$.

39. Let $y = (\ln x)^{1/2}$. Then $y' = \frac{1}{2}(\ln x)^{-1/2} \frac{d}{dx} \ln x = \boxed{\frac{1}{2x(\ln x)^{1/2}}}$.

40. Let $y = (\ln x)^{-1/2}$. Then $y' = -\frac{1}{2}(\ln x)^{-3/2} \frac{d}{dx} \ln x = \boxed{-\frac{1}{2x(\ln x)^{3/2}}}$.

41. Let $y = \sin(\ln \theta)$. Then $y' = \cos(\ln \theta) \frac{d}{d\theta} \ln \theta = \boxed{\cos(\ln \theta) \cdot \frac{1}{\theta}}$.

42. Let $y = \cos(\ln \theta)$. Then $y' = -\sin(\ln \theta) \frac{d}{d\theta} \ln \theta = \boxed{-\sin(\ln \theta) \cdot \frac{1}{\theta}}$.

43. Let $y = x \ln \sqrt{\cos(2x)} = \frac{1}{2}x \ln(\cos(2x))$. Then

$$\begin{aligned} y' &= \frac{1}{2}x \frac{d}{dx} \ln(\cos(2x)) + \ln(\cos(2x)) \frac{d}{dx} \left(\frac{1}{2}x \right) = \frac{1}{2}x \cdot \frac{1}{\cos(2x)} \frac{d}{dx} \cos(2x) + \frac{1}{2} \ln(\cos(2x)) \\ &= \frac{x}{2\cos(2x)} \cdot (-\sin(2x)) \frac{d}{dx}(2x) + \ln \sqrt{\cos(2x)} \\ &= -\frac{x \sin(2x)}{\cos(2x)} + \ln \sqrt{\cos(2x)} = \boxed{-x \tan(2x) + \ln \sqrt{\cos(2x)}}. \end{aligned}$$

44. Let $y = x^2 \ln \sqrt{\sin(2x)} = \frac{1}{2}x^2 \ln(\sin(2x))$. Then

$$\begin{aligned}
 y' &= \frac{1}{2}x^2 \frac{d}{dx} \ln(\sin(2x)) + \ln(\sin(2x)) \frac{d}{dx} \left(\frac{1}{2}x^2 \right) = \frac{1}{2}x^2 \cdot \frac{1}{\sin(2x)} \frac{d}{dx} \sin(2x) + x \ln(\sin(2x)) \\
 &= \frac{x^2}{2 \sin(2x)} \cdot \cos(2x) \frac{d}{dx} (2x) + x \ln(\sin(2x)) \\
 &= \frac{x^2 \cos(2x)}{\sin(2x)} + x \ln(\sin(2x)) = \boxed{x^2 \cot(2x) + x \ln(\sin(2x))}.
 \end{aligned}$$

45. Let $x \ln y + y \ln x = 2$. Then

$$\begin{aligned}
 \frac{d}{dx} (x \ln y + y \ln x) &= \frac{d}{dx} 2 \\
 \frac{d}{dx} (x \ln y) + \frac{d}{dx} (y \ln x) &= 0 \\
 \frac{x}{y} \frac{dy}{dx} + \ln y + \frac{y}{x} + \ln x \frac{dy}{dx} &= 0 \\
 \left(\frac{x}{y} + \ln x \right) \frac{dy}{dx} &= - \left(\frac{y}{x} + \ln y \right) \\
 \frac{dy}{dx} &= - \frac{\frac{y}{x} + \ln y}{\frac{x}{y} + \ln x} = \boxed{- \frac{y^2 + xy \ln y}{x^2 + xy \ln x}}.
 \end{aligned}$$

46. Let $\frac{\ln y}{x} + \frac{\ln x}{y} = 2$. Then

$$\begin{aligned}
 \frac{d}{dx} \left(\frac{\ln y}{x} + \frac{\ln x}{y} \right) &= \frac{d}{dx} 2 \\
 \frac{d}{dx} \left(\frac{\ln y}{x} \right) + \frac{d}{dx} \left(\frac{\ln x}{y} \right) &= 0 \\
 \frac{\frac{x}{y} \frac{dy}{dx} - \ln y}{x^2} + \frac{\frac{y}{x} - \ln x \frac{dy}{dx}}{y^2} &= 0 \\
 xy \frac{dy}{dx} - y^2 \ln y + xy - x^2 \ln x \frac{dy}{dx} &= 0 \\
 \frac{dy}{dx} &= \boxed{\frac{y^2 \ln y - xy}{xy - x^2 \ln x}}.
 \end{aligned}$$

47. Let $\ln(x^2 + y^2) = x + y$. Then

$$\begin{aligned}
 \frac{d}{dx} \ln(x^2 + y^2) &= \frac{d}{dx} (x + y) \\
 \frac{1}{x^2 + y^2} \frac{d}{dx} (x^2 + y^2) &= 1 + \frac{dy}{dx} \\
 \frac{1}{x^2 + y^2} \left(2x + 2y \frac{dy}{dx} \right) &= 1 + \frac{dy}{dx} \\
 2x + 2y \frac{dy}{dx} &= x^2 + y^2 + (x^2 + y^2) \frac{dy}{dx} \\
 \frac{dy}{dx} &= \boxed{\frac{x^2 + y^2 - 2x}{2y - x^2 - y^2}}.
 \end{aligned}$$

48. Let $\ln(x^2 - y^2) = x - y$. Then

$$\begin{aligned}\frac{d}{dx} \ln(x^2 - y^2) &= \frac{d}{dx}(x - y) \\ \frac{1}{x^2 - y^2} \frac{d}{dx}(x^2 - y^2) &= 1 - \frac{dy}{dx} \\ \frac{1}{x^2 - y^2} \left(2x - 2y \frac{dy}{dx} \right) &= 1 - \frac{dy}{dx} \\ 2x - 2y \frac{dy}{dx} &= x^2 - y^2 - (x^2 - y^2) \frac{dy}{dx} \\ \frac{dy}{dx} &= \boxed{\frac{x^2 - y^2 - 2x}{x^2 - y^2 - 2y}}.\end{aligned}$$

49. Let $\ln \frac{y}{x} = y$ or $\ln y - \ln x = y$. Then

$$\begin{aligned}\frac{d}{dx}(\ln y - \ln x) &= \frac{dy}{dx} \\ \frac{1}{y} \frac{dy}{dx} - \frac{1}{x} &= \frac{dy}{dx} \\ x \frac{dy}{dx} - y &= xy \frac{dy}{dx} \\ \frac{dy}{dx} &= \frac{y}{x - xy} = \boxed{\frac{y}{x(1 - y)}}.\end{aligned}$$

50. Let $\ln \frac{y}{x} - \ln \frac{x}{y} = 1$ or $2 \ln y - 2 \ln x = 1$. Then

$$\begin{aligned}\frac{d}{dx}(2 \ln y - 2 \ln x) &= \frac{d}{dx} 1 \\ \frac{2}{y} \frac{dy}{dx} - \frac{2}{x} &= 0 \\ \frac{dy}{dx} &= \boxed{\frac{y}{x}}.\end{aligned}$$

51. Let $y = (x^2 + 1)^2(2x^3 - 1)^4$. Then

$$\ln y = \ln[(x^2 + 1)^2(2x^3 - 1)^4] = \ln[(x^2 + 1)^2] + \ln[(2x^3 - 1)^4] = 2 \ln(x^2 + 1) + 4 \ln(2x^3 - 1),$$

and

$$\frac{d}{dx} \ln y = \frac{d}{dx} [2 \ln(x^2 + 1) + 4 \ln(2x^3 - 1)].$$

This yields

$$\begin{aligned}\frac{1}{y} \frac{dy}{dx} &= \frac{2}{x^2 + 1} \frac{d}{dx}(x^2 + 1) + \frac{4}{2x^3 - 1} \frac{d}{dx}(2x^3 - 1) \\ &= \frac{2}{x^2 + 1} \cdot 2x + \frac{4}{2x^3 - 1} \cdot 6x^2 = \frac{4x}{x^2 + 1} + \frac{24x^2}{2x^3 - 1},\end{aligned}$$

so that

$$\frac{dy}{dx} = y \left(\frac{4x}{x^2 + 1} + \frac{24x^2}{2x^3 - 1} \right) = \boxed{(x^2 + 1)^2(2x^3 - 1)^4 \left(\frac{4x}{x^2 + 1} + \frac{24x^2}{2x^3 - 1} \right)}.$$

52. Let $y = (3x^2 + 4)^3(x^2 + 1)^4$. Then

$$\ln y = \ln[(3x^2 + 4)^3(x^2 + 1)^4] = \ln[(3x^2 + 4)^3] + \ln[(x^2 + 1)^4] = 3 \ln(3x^2 + 4) + 4 \ln(x^2 + 1),$$

and

$$\frac{d}{dx} \ln y = \frac{d}{dx} [3 \ln(3x^2 + 4) + 4 \ln(x^2 + 1)].$$

This yields

$$\begin{aligned} \frac{1}{y} \frac{dy}{dx} &= \frac{3}{3x^2 + 4} \frac{d}{dx} (3x^2 + 4) + \frac{4}{x^2 + 1} \frac{d}{dx} (x^2 + 1) \\ &= \frac{3}{3x^2 + 4} \cdot 6x + \frac{4}{x^2 + 1} \cdot 2x = \frac{18x}{3x^2 + 4} + \frac{8x}{x^2 + 1}, \end{aligned}$$

so that

$$\frac{dy}{dx} = y \left(\frac{18x}{3x^2 + 4} + \frac{8x}{x^2 + 1} \right) = \boxed{(3x^2 + 4)^3(x^2 + 1)^4 \left(\frac{18x}{3x^2 + 4} + \frac{8x}{x^2 + 1} \right)}.$$

53. Let $y = \frac{x^2(x^3 + 1)}{\sqrt{x^2 + 1}}$. Then

$$\ln y = \ln \left[\frac{x^2(x^3 + 1)}{\sqrt{x^2 + 1}} \right] = \ln x^2 + \ln(x^3 + 1) - \ln \sqrt{x^2 + 1} = 2 \ln x + \ln(x^3 + 1) - \frac{1}{2} \ln(x^2 + 1),$$

and

$$\frac{d}{dx} \ln y = \frac{d}{dx} \left[2 \ln x + \ln(x^3 + 1) - \frac{1}{2} \ln(x^2 + 1) \right].$$

This yields

$$\begin{aligned} \frac{1}{y} \frac{dy}{dx} &= \frac{2}{x} + \frac{1}{x^3 + 1} \frac{d}{dx} (x^3 + 1) - \frac{1}{2(x^2 + 1)} \frac{d}{dx} (x^2 + 1) \\ &= \frac{2}{x} + \frac{1}{x^3 + 1} \cdot 3x^2 - \frac{1}{2(x^2 + 1)} \cdot 2x = \frac{2}{x} + \frac{3x^2}{x^3 + 1} - \frac{x}{x^2 + 1}, \end{aligned}$$

so that

$$\frac{dy}{dx} = y \left(\frac{2}{x} + \frac{3x^2}{x^3 + 1} - \frac{x}{x^2 + 1} \right) = \boxed{\frac{x^2(x^3 + 1)}{\sqrt{x^2 + 1}} \left(\frac{2}{x} + \frac{3x^2}{x^3 + 1} - \frac{x}{x^2 + 1} \right)}.$$

54. Let $y = \frac{\sqrt{x}(x^3 + 2)^2}{\sqrt[3]{3x + 4}}$. Then

$$\ln y = \ln \left[\frac{\sqrt{x}(x^3 + 2)^2}{\sqrt[3]{3x + 4}} \right] = \ln \sqrt{x} + \ln(x^3 + 2)^2 - \ln \sqrt[3]{3x + 4} = \frac{1}{2} \ln x + 2 \ln(x^3 + 2) - \frac{1}{3} \ln(3x + 4),$$

and

$$\frac{d}{dx} \ln y = \frac{d}{dx} \left[\frac{1}{2} \ln x + 2 \ln(x^3 + 2) - \frac{1}{3} \ln(3x + 4) \right].$$

This yields

$$\begin{aligned} \frac{1}{y} \frac{dy}{dx} &= \frac{1}{2x} + \frac{2}{x^3 + 2} \frac{d}{dx} (x^3 + 2) - \frac{1}{3(3x + 4)} \frac{d}{dx} (3x + 4) \\ &= \frac{1}{2x} + \frac{2}{x^3 + 2} \cdot 3x^2 - \frac{1}{3(3x + 4)} \cdot 3 = \frac{1}{2x} + \frac{6x^2}{x^3 + 2} - \frac{1}{3x + 4}, \end{aligned}$$

so that

$$\frac{dy}{dx} = y \left(\frac{1}{2x} + \frac{6x^2}{x^3 + 2} - \frac{1}{3x + 4} \right) = \boxed{\frac{\sqrt{x}(x^3 + 2)^2}{\sqrt[3]{3x + 4}} \left(\frac{1}{2x} + \frac{6x^2}{x^3 + 2} - \frac{1}{3x + 4} \right)}.$$

55. Let $y = \frac{x \cos x}{(x^2 + 1)^3 \sin x}$. Then

$$\begin{aligned}\ln y &= \ln \left[\frac{x \cos x}{(x^2 + 1)^3 \sin x} \right] = \ln x + \ln \cos x - \ln(x^2 + 1)^3 - \ln \sin x \\ &= \ln x + \ln \cos x - 3 \ln(x^2 + 1) - \ln \sin x,\end{aligned}$$

and

$$\frac{d}{dx} \ln y = \frac{d}{dx} (\ln x + \ln \cos x - 3 \ln(x^2 + 1) - \ln \sin x).$$

This yields

$$\begin{aligned}\frac{1}{y} \frac{dy}{dx} &= \frac{1}{x} + \frac{1}{\cos x} \frac{d}{dx} \cos x - \frac{3}{x^2 + 1} \frac{d}{dx} (x^2 + 1) - \frac{1}{\sin x} \frac{d}{dx} \sin x \\ &= \frac{1}{x} + \frac{1}{\cos x} \cdot (-\sin x) - \frac{3}{x^2 + 1} \cdot 2x - \frac{1}{\sin x} \cdot \cos x = \frac{1}{x} - \tan x - \frac{6x}{x^2 + 1} - \cot x,\end{aligned}$$

so that

$$\frac{dy}{dx} = y \left(\frac{1}{x} - \tan x - \frac{6x}{x^2 + 1} - \cot x \right) = \boxed{\frac{x \cos x}{(x^2 + 1)^3 \sin x} \left(\frac{1}{x} - \tan x - \frac{6x}{x^2 + 1} - \cot x \right)}.$$

56. Let $y = \frac{x \sin x}{(1 + e^x)^3 \cos x}$. Then

$$\begin{aligned}\ln y &= \ln \left[\frac{x \sin x}{(1 + e^x)^3 \cos x} \right] = \ln x + \ln \sin x - \ln(1 + e^x)^3 - \ln \cos x \\ &= \ln x + \ln \sin x - 3 \ln(1 + e^x) - \ln \cos x,\end{aligned}$$

and

$$\frac{d}{dx} \ln y = \frac{d}{dx} (\ln x + \ln \sin x - 3 \ln(1 + e^x) - \ln \cos x).$$

This yields

$$\begin{aligned}\frac{1}{y} \frac{dy}{dx} &= \frac{1}{x} + \frac{1}{\sin x} \frac{d}{dx} \sin x - \frac{3}{1 + e^x} \frac{d}{dx} (1 + e^x) - \frac{1}{\cos x} \frac{d}{dx} \cos x \\ &= \frac{1}{x} + \frac{1}{\sin x} \cdot \cos x - \frac{3}{1 + e^x} \cdot e^x - \frac{1}{\cos x} \cdot (-\sin x) = \frac{1}{x} + \cot x - \frac{3e^x}{1 + e^x} + \tan x,\end{aligned}$$

so that

$$\frac{dy}{dx} = y \left(\frac{1}{x} + \cot x - \frac{3e^x}{1 + e^x} + \tan x \right) = \boxed{\frac{x \sin x}{(1 + e^x)^3 \cos x} \left(\frac{1}{x} + \cot x - \frac{3e^x}{1 + e^x} + \tan x \right)}.$$

57. Let $y = (3x)^x$. Then

$$\ln y = \ln[(3x)^x] = x \ln(3x) = x (\ln 3 + \ln x),$$

and

$$\frac{d}{dx} \ln y = \frac{d}{dx} [x (\ln 3 + \ln x)].$$

This yields

$$\frac{1}{y} \frac{dy}{dx} = x \frac{d}{dx} (\ln 3 + \ln x) + (\ln 3 + \ln x) \frac{d}{dx} x = x \cdot \frac{1}{x} + \ln 3 + \ln x = 1 + \ln(3x),$$

so that

$$\frac{dy}{dx} = y(1 + \ln(3x)) = \boxed{(3x)^x (1 + \ln(3x))}.$$

58. Let $y = (x - 1)^x$. Then

$$\ln y = \ln[(x - 1)^x] = x \ln(x - 1),$$

and

$$\frac{d}{dx} \ln y = \frac{d}{dx} [x \ln(x - 1)].$$

This yields

$$\frac{1}{y} \frac{dy}{dx} = x \frac{d}{dx} \ln(x - 1) + \ln(x - 1) \frac{d}{dx} x = x \cdot \frac{1}{x - 1} + \ln(x - 1) = \frac{x}{x - 1} + \ln(x - 1),$$

so that

$$\frac{dy}{dx} = y \left(\frac{x}{x - 1} + \ln(x - 1) \right) = \boxed{(x - 1)^x \left(\frac{x}{x - 1} + \ln(x - 1) \right)}.$$

59. Let $y = x^{\ln x}$. Then

$$\ln y = \ln(x^{\ln x}) = \ln x \cdot \ln x = (\ln x)^2,$$

and

$$\frac{d}{dx} \ln y = \frac{d}{dx} (\ln x)^2.$$

This yields

$$\frac{1}{y} \frac{dy}{dx} = 2 \ln x \frac{d}{dx} \ln x = \frac{2 \ln x}{x},$$

so that

$$\frac{dy}{dx} = y \frac{2 \ln x}{x} = x^{\ln x} \frac{2 \ln x}{x} = \boxed{2x^{\ln x} \frac{\ln x}{x}}.$$

60. Let $y = (2x)^{\ln x}$. Then

$$\ln y = \ln[(2x)^{\ln x}] = \ln x \cdot \ln(2x) = \ln x \cdot (\ln x + \ln 2) = (\ln x)^2 + \ln 2 \ln x,$$

and

$$\frac{d}{dx} \ln y = \frac{d}{dx} [(\ln x)^2 + \ln 2 \ln x].$$

This yields

$$\frac{1}{y} \frac{dy}{dx} = 2 \ln x \frac{d}{dx} \ln x + \frac{\ln 2}{x} = \frac{2 \ln x}{x} + \frac{\ln 2}{x} = \frac{2 \ln x + \ln 2}{x},$$

so that

$$\frac{dy}{dx} = y \frac{2 \ln x + \ln 2}{x} = \boxed{(2x)^{\ln x} \frac{2 \ln x + \ln 2}{x}}.$$

61. Let $y = x^{x^2}$. Then

$$\ln y = \ln x^{x^2} = x^2 \ln x,$$

and

$$\frac{d}{dx} \ln y = \frac{d}{dx} (x^2 \ln x).$$

This yields

$$\frac{1}{y} \frac{dy}{dx} = x^2 \frac{d}{dx} \ln x + \ln x \frac{d}{dx} x^2 = x^2 \cdot \frac{1}{x} + 2x \ln x = x + 2x \ln x,$$

so that

$$\frac{dy}{dx} = y(x + 2x \ln x) = \boxed{x^{x^2} (x + 2x \ln x)}.$$

62. Let $y = (3x)^{\sqrt{x}}$. Then

$$\ln y = \ln[(3x)^{\sqrt{x}}] = \sqrt{x} \ln(3x),$$

and

$$\frac{d}{dx} \ln y = \frac{d}{dx} [\sqrt{x} \ln(3x)].$$

This yields

$$\frac{1}{y} \frac{dy}{dx} = \sqrt{x} \frac{d}{dx} \ln(3x) + \ln(3x) \frac{d}{dx} \sqrt{x} = \frac{\sqrt{x}}{3x} \frac{d}{dx} (3x) + \frac{1}{2} x^{-1/2} \ln(3x) = \frac{\sqrt{x}}{x} + \frac{\ln(3x)}{2\sqrt{x}} = \frac{1}{\sqrt{x}} + \frac{\ln(3x)}{2\sqrt{x}},$$

so that

$$\frac{dy}{dx} = y \left(\frac{1}{\sqrt{x}} + \frac{\ln(3x)}{2\sqrt{x}} \right) = \boxed{(3x)^{\sqrt{x}} \frac{2 + \ln(3x)}{2\sqrt{x}}}.$$

63. Let $y = x^{e^x}$. Then

$$\ln y = \ln(x^{e^x}) = e^x \ln x,$$

and

$$\frac{d}{dx} \ln y = \frac{d}{dx} (e^x \ln x).$$

This yields

$$\frac{1}{y} \frac{dy}{dx} = e^x \frac{d}{dx} \ln x + \ln x \frac{d}{dx} e^x = \frac{e^x}{x} + e^x \ln x,$$

so that

$$\frac{dy}{dx} = y \left(\frac{e^x}{x} + e^x \ln x \right) = \boxed{x^{e^x} \left(\frac{e^x}{x} + e^x \ln x \right)}.$$

64. Let $y = (x^2 + 1)^{e^x}$. Then

$$\ln y = \ln[(x^2 + 1)^{e^x}] = e^x \ln(x^2 + 1),$$

and

$$\frac{d}{dx} \ln y = \frac{d}{dx} [e^x \ln(x^2 + 1)].$$

This yields

$$\begin{aligned} \frac{1}{y} \frac{dy}{dx} &= e^x \frac{d}{dx} \ln(x^2 + 1) + \ln(x^2 + 1) \frac{d}{dx} e^x \\ &= \frac{e^x}{x^2 + 1} \frac{d}{dx} (x^2 + 1) + e^x \ln(x^2 + 1) = \frac{2xe^x}{x^2 + 1} + e^x \ln(x^2 + 1), \end{aligned}$$

so that

$$\frac{dy}{dx} = y \left(\frac{2xe^x}{x^2 + 1} + e^x \ln(x^2 + 1) \right) = \boxed{(x^2 + 1)^{e^x} \left(\frac{2xe^x}{x^2 + 1} + e^x \ln(x^2 + 1) \right)}.$$

65. Let $y = x^{\sin x}$. Then

$$\ln y = \ln[x^{\sin x}] = \sin x \ln x,$$

and

$$\frac{d}{dx} \ln y = \frac{d}{dx} (\sin x \ln x).$$

This yields

$$\frac{1}{y} \frac{dy}{dx} = \sin x \frac{d}{dx} \ln x + \ln x \frac{d}{dx} \sin x = \frac{\sin x}{x} + \cos x \ln x,$$

so that

$$\frac{dy}{dx} = y \left(\frac{\sin x}{x} + \cos x \ln x \right) = \boxed{x^{\sin x} \left(\frac{\sin x}{x} + \cos x \ln x \right)}.$$

66. Let $y = x^{\cos x}$. Then

$$\ln y = \ln[x^{\cos x}] = \cos x \ln x,$$

and

$$\frac{d}{dx} \ln y = \frac{d}{dx} (\cos x \ln x).$$

This yields

$$\frac{1}{y} \frac{dy}{dx} = \cos x \frac{d}{dx} \ln x + \ln x \frac{d}{dx} \cos x = \frac{\cos x}{x} - \sin x \ln x,$$

so that

$$\frac{dy}{dx} = y \left(\frac{\cos x}{x} - \sin x \ln x \right) = \boxed{x^{\cos x} \left(\frac{\cos x}{x} - \sin x \ln x \right)}.$$

67. Let $y = (\sin x)^x$. Then

$$\ln y = \ln[(\sin x)^x] = x \ln(\sin x),$$

and

$$\frac{d}{dx} \ln y = \frac{d}{dx} [x \ln(\sin x)].$$

This yields

$$\begin{aligned} \frac{1}{y} \frac{dy}{dx} &= x \frac{d}{dx} \ln(\sin x) + \ln(\sin x) \frac{d}{dx} x = \frac{x}{\sin x} \frac{d}{dx} \sin x + \ln(\sin x) \\ &= \frac{x}{\sin x} \cdot \cos x + \ln(\sin x) = x \cot x + \ln(\sin x), \end{aligned}$$

so that

$$\frac{dy}{dx} = y(x \cot x + \ln(\sin x)) = \boxed{(\sin x)^x (x \cot x + \ln(\sin x))}.$$

68. Let $y = (\cos x)^x$. Then

$$\ln y = \ln[(\cos x)^x] = x \ln(\cos x),$$

and

$$\frac{d}{dx} \ln y = \frac{d}{dx} [x \ln(\cos x)].$$

This yields

$$\begin{aligned} \frac{1}{y} \frac{dy}{dx} &= x \frac{d}{dx} \ln(\cos x) + \ln(\cos x) \frac{d}{dx} x = \frac{x}{\cos x} \frac{d}{dx} \cos x + \ln(\cos x) \\ &= \frac{x}{\cos x} \cdot (-\sin x) + \ln(\cos x) = -x \tan x + \ln(\cos x), \end{aligned}$$

so that

$$\frac{dy}{dx} = y(-x \tan x + \ln(\cos x)) = \boxed{(\cos x)^x (-x \tan x + \ln(\cos x))}.$$

69. Let $y = (\sin x)^{\cos x}$. Then

$$\ln y = \ln[(\sin x)^{\cos x}] = \cos x \ln(\sin x),$$

and

$$\frac{d}{dx} \ln y = \frac{d}{dx} [\cos x \ln(\sin x)].$$

This yields

$$\frac{1}{y} \frac{dy}{dx} = \cos x \frac{d}{dx} \ln(\sin x) + \ln(\sin x) \frac{d}{dx} \cos x = \frac{\cos x}{\sin x} \frac{d}{dx} \sin x - \sin x \ln(\sin x) = \cos x \cot x - \sin x \ln(\sin x),$$

so that

$$\frac{dy}{dx} = y(\cos x \cot x - \sin x \ln(\sin x)) = \boxed{(\sin x)^{\cos x} (\cos x \cot x - \sin x \ln(\sin x))}.$$

70. Let $y = (\sin x)^{\tan x}$. Then

$$\ln y = \ln[(\sin x)^{\tan x}] = \tan x \ln(\sin x),$$

and

$$\frac{d}{dx} \ln y = \frac{d}{dx} [\tan x \ln(\sin x)].$$

This yields

$$\begin{aligned} \frac{1}{y} \frac{dy}{dx} &= \tan x \frac{d}{dx} \ln(\sin x) + \ln(\sin x) \frac{d}{dx} \tan x = \frac{\tan x}{\sin x} \frac{d}{dx} \sin x + \sec^2 x \ln(\sin x) \\ &= \frac{1}{\cos x} \cdot \cos x + \sec^2 x \ln(\sin x) = 1 + \sec^2 x \ln(\sin x), \end{aligned}$$

so that

$$\frac{dy}{dx} = y(1 + \sec^2 x \ln(\sin x)) = \boxed{(\sin x)^{\tan x} (1 + \sec^2 x \ln(\sin x))}.$$

71. Let $x^y = 4$. Then

$$\ln(x^y) = y \ln x = \ln 4,$$

and

$$\frac{d}{dx} (y \ln x) = \frac{d}{dx} \ln 4.$$

This yields

$$\begin{aligned} y \cdot \frac{1}{x} + \ln x \cdot \frac{dy}{dx} &= 0 \\ \ln x \cdot \frac{dy}{dx} &= -\frac{y}{x} \\ \frac{dy}{dx} &= \boxed{-\frac{y}{x \ln x}}. \end{aligned}$$

Here, we can solve for y explicitly as

$$y = \frac{\ln 4}{\ln x},$$

so the derivative can also be expressed explicitly in terms of x :

$$\frac{dy}{dx} = -\frac{\frac{\ln 4}{\ln x}}{x \ln x} = -\frac{\ln 4}{x(\ln x)^2}.$$

72. Let $y^x = 10$. Then

$$\ln(y^x) = \ln 10 \quad \text{or} \quad x \ln y = \ln 10.$$

By implicit differentiation it follows that

$$\begin{aligned} \frac{d}{dx} (x \ln y) &= \frac{d}{dx} \ln 10 \\ x \frac{d}{dx} \ln y + \ln y \frac{d}{dx} x &= 0 \\ \frac{x}{y} \frac{dy}{dx} + \ln y &= 0 \\ \frac{dy}{dx} &= \boxed{-\frac{y \ln y}{x}}. \end{aligned}$$

73. Let $f(x) = \ln(5x)$. Then

$$f'(x) = \frac{1}{5x} \frac{d}{dx}(5x) = \frac{1}{5x} \cdot 5 = \frac{1}{x},$$

and the slope of the tangent line at the point $\left(\frac{1}{5}, 0\right)$ is

$$m_{\text{sec}} = f'\left(\frac{1}{5}\right) = \frac{1}{1/5} = 5.$$

The equation of the tangent line is then

$$y - 0 = 5\left(x - \frac{1}{5}\right) \quad \text{or} \quad \boxed{y = 5x - 1}.$$

74. Let $f(x) = x \ln x$. Then

$$f'(x) = x \frac{d}{dx} \ln x + \ln x \frac{d}{dx} x = x \cdot \frac{1}{x} + \ln x = 1 + \ln x,$$

and the slope of the tangent line at the point $(1, 0)$ is

$$m_{\text{tan}} = f'(1) = 1 + \ln 1 = 1 + 0 = 1.$$

The equation of the tangent line is then

$$y - 0 = 1(x - 1) \quad \text{or} \quad \boxed{y = x - 1}.$$

75. Let $y = \frac{x^2 \sqrt{3x-2}}{(x-1)^2}$. Then

$$\ln y = \ln \left[\frac{x^2 \sqrt{3x-2}}{(x-1)^2} \right] = \ln x^2 + \ln \sqrt{3x-2} - \ln(x-1)^2 = 2 \ln x + \frac{1}{2} \ln(3x-2) - 2 \ln(x-1),$$

and

$$\frac{d}{dx} \ln y = \frac{d}{dx} \left(2 \ln x + \frac{1}{2} \ln(3x-2) - 2 \ln(x-1) \right).$$

This yields

$$\begin{aligned} \frac{1}{y} \frac{dy}{dx} &= \frac{2}{x} + \frac{1}{2(3x-2)} \frac{d}{dx}(3x-2) - \frac{2}{x-1} \frac{d}{dx}(x-1) \\ &= \frac{2}{x} + \frac{1}{2(3x-2)} \cdot 3 - \frac{2}{x-1} \cdot 1 = \frac{2}{x} + \frac{3}{2(3x-2)} - \frac{2}{x-1}, \end{aligned}$$

so that

$$\frac{dy}{dx} = y \left(\frac{2}{x} + \frac{3}{2(3x-2)} - \frac{2}{x-1} \right) = \frac{x^2 \sqrt{3x-2}}{(x-1)^2} \left(\frac{2}{x} + \frac{3}{2(3x-2)} - \frac{2}{x-1} \right).$$

The slope of the tangent line at the point $(2, 8)$ is

$$m_{\text{tan}} = \frac{4\sqrt{4}}{1} \left(\frac{2}{2} + \frac{3}{2(4)} - \frac{2}{1} \right) = 8 \left(-\frac{5}{8} \right) = -5,$$

and the equation of the tangent line is

$$y - 8 = -5(x - 2) \quad \text{or} \quad \boxed{y = -5x + 18}.$$

76. Let $y = \frac{x(\sqrt[3]{x} + 1)^2}{\sqrt{x+1}}$. Then

$$\ln y = \ln \left[\frac{x(\sqrt[3]{x} + 1)^2}{\sqrt{x+1}} \right] = \ln x + \ln(\sqrt[3]{x} + 1)^2 - \ln \sqrt{x+1} = \ln x + 2 \ln(\sqrt[3]{x} + 1) - \frac{1}{2} \ln(x+1),$$

and

$$\frac{d}{dx} \ln y = \frac{d}{dx} \left(\ln x + 2 \ln(\sqrt[3]{x} + 1) - \frac{1}{2} \ln(x+1) \right).$$

This yields

$$\begin{aligned} \frac{1}{y} \frac{dy}{dx} &= \frac{1}{x} + \frac{2}{\sqrt[3]{x} + 1} \frac{d}{dx}(\sqrt[3]{x} + 1) - \frac{1}{2(x+1)} \frac{d}{dx}(x+1) \\ &= \frac{1}{x} + \frac{2}{\sqrt[3]{x} + 1} \cdot \frac{1}{3} x^{-2/3} - \frac{1}{2(x+1)} \cdot 1 = \frac{1}{x} + \frac{2}{3\sqrt[3]{x^2}(\sqrt[3]{x} + 1)} - \frac{1}{2(x+1)}, \end{aligned}$$

so that

$$\frac{dy}{dx} = y \left(\frac{1}{x} + \frac{2}{3\sqrt[3]{x^2}(\sqrt[3]{x} + 1)} - \frac{1}{2(x+1)} \right) = \frac{x(\sqrt[3]{x} + 1)^2}{\sqrt{x+1}} \left(\frac{1}{x} + \frac{2}{3\sqrt[3]{x^2}(\sqrt[3]{x} + 1)} - \frac{1}{2(x+1)} \right).$$

The slope of the tangent line at the point (8, 24) is

$$m_{\tan} = \frac{8(3)^2}{3} \left(\frac{1}{8} + \frac{2}{3(4)(3)} - \frac{1}{2(9)} \right) = 24 \cdot \frac{1}{8} = 3,$$

and the equation of the tangent line is

$$y - 24 = 3(x - 8) \quad \text{or} \quad \boxed{y = 3x}.$$

77. $\lim_{n \rightarrow \infty} \left(1 + \frac{1}{n} \right)^{2n} = \left[\lim_{n \rightarrow \infty} \left(1 + \frac{1}{n} \right)^n \right]^2 = \boxed{e^2}.$

78. $\lim_{n \rightarrow \infty} \left(1 + \frac{1}{n} \right)^{n/2} = \sqrt{\lim_{n \rightarrow \infty} \left(1 + \frac{1}{n} \right)^n} = \boxed{\sqrt{e}}.$

79. First write

$$\lim_{n \rightarrow \infty} \left(1 + \frac{1}{3n} \right)^n = \lim_{n \rightarrow \infty} \left(1 + \frac{1}{3n} \right)^{3n/3} = \sqrt[3]{\lim_{n \rightarrow \infty} \left(1 + \frac{1}{3n} \right)^{3n}}.$$

Now, let $k = 3n$. As $n \rightarrow \infty$, $k \rightarrow \infty$ as well, so

$$\lim_{n \rightarrow \infty} \left(1 + \frac{1}{3n} \right)^n = \sqrt[3]{\lim_{n \rightarrow \infty} \left(1 + \frac{1}{3n} \right)^{3n}} = \sqrt[3]{\lim_{k \rightarrow \infty} \left(1 + \frac{1}{k} \right)^k} = \sqrt[3]{e} = \boxed{e^{1/3}}.$$

80. First write

$$\lim_{n \rightarrow \infty} \left(1 + \frac{4}{n} \right)^n = \lim_{n \rightarrow \infty} \left(1 + \frac{1}{n/4} \right)^{4n/4} = \left[\lim_{n \rightarrow \infty} \left(1 + \frac{1}{n/4} \right)^{n/4} \right]^4.$$

Now, let $k = n/4$. As $n \rightarrow \infty$, $k \rightarrow \infty$ as well, so

$$\lim_{n \rightarrow \infty} \left(1 + \frac{4}{n} \right)^n = \left[\lim_{n \rightarrow \infty} \left(1 + \frac{1}{n/4} \right)^{n/4} \right]^4 = \left[\lim_{k \rightarrow \infty} \left(1 + \frac{1}{k} \right)^k \right]^4 = \boxed{e^4}.$$

Applications and Extensions

81. Let $f(x) = x^9 \ln x$. Then

$$\begin{aligned}\frac{df}{dx} &= x^9 \cdot \frac{1}{x} + \ln x \cdot 9x^8 = x^8 + 9x^8 \ln x \\ \frac{d^2 f}{dx^2} &= 8x^7 + 9x^8 \cdot \frac{1}{x} + \ln x \cdot 72x^7 = 17x^7 + 72x^7 \ln x \\ \frac{d^3 f}{dx^3} &= 119x^6 + 72x^7 \cdot \frac{1}{x} + \ln x \cdot 504x^6 = 191x^6 + 504x^6 \ln x,\end{aligned}$$

and so on. Note that with each derivative, the exponent on x decreases by one. By the ninth derivative, the exponent on x will be $9 - 9 = 0$; in other words, the ninth derivative will be of the form $c + d \ln x$, for some constants c and d . Then, the tenth derivative will be d/x . To identify the constant d , note that the multiplier on the natural logarithm term is 9 for the first derivative, $72 = 9(8)$ for the second derivative, $504 = 9(8)(7)$ for the third derivative, and so on. By the ninth derivative, the multiplier on the natural logarithm term will then be $9(8)(7) \cdots (2)(1) = 9!$. Finally,

$$\frac{d^{10}}{dx^{10}}(x^9 \ln x) = \boxed{\frac{9!}{x} = \frac{362880}{x}}.$$

82. Let $f(x) = \ln(x - 1)$. Then

$$\begin{aligned}f'(x) &= \frac{1}{x-1} \frac{d}{dx}(x-1) = \frac{1}{x-1} = (x-1)^{-1}; \\ f''(x) &= -(x-1)^{-2} \frac{d}{dx}(x-1) = -(x-1)^{-2}; \\ f'''(x) &= 2(x-1)^{-3} \frac{d}{dx}(x-1) = 2(x-1)^{-3}; \\ f^{(4)}(x) &= -6(x-1)^{-4} \frac{d}{dx}(x-1) = -6(x-1)^{-4};\end{aligned}$$

and so on. Note the elements in the pattern: the power on $x - 1$ in each derivative is the negative of the order of the derivative; the sign on the derivative alternates starting with positive on the first derivative; and the coefficients, 1, 1, 2, 6, are respectively $0!$, $1!$, $2!$, and $3!$. Thus

$$f^{(n)}(x) = \boxed{(-1)^{n-1}(n-1)!(x-1)^{-n}}.$$

83. Let $y = \ln(x^2 + y^2)$. Then

$$\begin{aligned}\frac{dy}{dx} &= \frac{d}{dx} \ln(x^2 + y^2) \\ \frac{dy}{dx} &= \frac{1}{x^2 + y^2} \frac{d}{dx}(x^2 + y^2) \\ \frac{dy}{dx} &= \frac{1}{x^2 + y^2} \left(2x + 2y \frac{dy}{dx} \right) \\ \left(1 - \frac{2y}{x^2 + y^2} \right) \frac{dy}{dx} &= \frac{2x}{x^2 + y^2} \\ \frac{dy}{dx} &= \frac{2x}{x^2 + y^2 - 2y}.\end{aligned}$$

Therefore, at the point $(1, 0)$,

$$\frac{dy}{dx} = \frac{2}{1 + 0 - 0} = \boxed{2}.$$

84. Let $f(x) = \tan\left(\ln x - \frac{1}{\ln x}\right)$. Then

$$\begin{aligned} f'(x) &= \sec^2\left(\ln x - \frac{1}{\ln x}\right) \frac{d}{dx}\left(\ln x - \frac{1}{\ln x}\right) \\ &= \sec^2\left(\ln x - \frac{1}{\ln x}\right) \cdot \left(\frac{1}{x} + \frac{1}{(\ln x)^2} \frac{d}{dx} \ln x\right) = \left(\frac{1}{x} + \frac{1}{x(\ln x)^2}\right) \sec^2\left(\ln x - \frac{1}{\ln x}\right), \end{aligned}$$

so

$$f'(e) = \left(\frac{1}{e} + \frac{1}{e(\ln e)^2}\right) \sec^2\left(\ln e - \frac{1}{\ln e}\right) = \left(\frac{1}{e} + \frac{1}{e}\right) \sec^2\left(1 - \frac{1}{1}\right) = \frac{2}{e} \sec^2 0 = \boxed{\frac{2}{e}}.$$

85. Let $x > 0$, and consider the function $y = x^x = e^{\ln x^x} = e^{x \ln x}$. Then

$$y' = e^{x \ln x} \frac{d}{dx}(x \ln x) = x^x \left(x \cdot \frac{1}{x} + \ln x \cdot 1\right) = \boxed{x^x(1 + \ln x)}.$$

86. Let $x > 0$ and $k > 0$ be a constant. Consider the function $y = \ln(kx) = \ln k + \ln x$. Then $y' = 0 + \frac{1}{x} = \frac{1}{x}$.

87. Let $y = x \tan^{-1} \frac{x}{a} - \frac{1}{2} a \ln(x^2 + a^2)$. Then

$$\begin{aligned} y' &= x \frac{d}{dx} \tan^{-1} \frac{x}{a} + \tan^{-1} \frac{x}{a} - \frac{a}{2(x^2 + a^2)} \frac{d}{dx}(x^2 + a^2) \\ &= x \frac{1}{1 + (x/a)^2} \frac{d}{dx} \left(\frac{x}{a}\right) + \tan^{-1} \frac{x}{a} - \frac{ax}{x^2 + a^2} \\ &= \frac{ax}{a^2 + x^2} + \tan^{-1} \frac{x}{a} - \frac{ax}{x^2 + a^2} = \boxed{\tan^{-1} \frac{x}{a}}. \end{aligned}$$

88. Let $y = x \sin^{-1} \frac{x}{a} + a \ln \sqrt{a^2 - x^2} = x \sin^{-1} \frac{x}{a} + \frac{1}{2} a \ln(a^2 - x^2)$. Then

$$\begin{aligned} y' &= x \frac{d}{dx} \sin^{-1} \frac{x}{a} + \sin^{-1} \frac{x}{a} + \frac{a}{2(a^2 - x^2)} \frac{d}{dx}(a^2 - x^2) \\ &= x \frac{1}{\sqrt{1 - (x/a)^2}} \frac{d}{dx} \left(\frac{x}{a}\right) + \sin^{-1} \frac{x}{a} - \frac{ax}{a^2 - x^2} \\ &= \boxed{\frac{x}{\sqrt{a^2 - x^2}} + \sin^{-1} \frac{x}{a} - \frac{ax}{a^2 - x^2}}. \end{aligned}$$

89. (a) First write

$$\lim_{n \rightarrow \infty} \left(1 + \frac{r}{n}\right)^{nt} = \lim_{n \rightarrow \infty} \left(1 + \frac{1}{n/r}\right)^{rnt/r} = \left[\lim_{n \rightarrow \infty} \left(1 + \frac{1}{n/r}\right)^{n/r}\right]^{rt}.$$

Now, let $k = n/r$. As $n \rightarrow \infty$, $k \rightarrow \infty$ as well, so

$$\lim_{n \rightarrow \infty} \left(1 + \frac{r}{n}\right)^{nt} = \left[\lim_{n \rightarrow \infty} \left(1 + \frac{1}{n/r}\right)^{n/r}\right]^{rt} = \left[\lim_{k \rightarrow \infty} \left(1 + \frac{1}{k}\right)^k\right]^{rt} = e^{rt}.$$

Thus

$$A = \lim_{n \rightarrow \infty} P \left(1 + \frac{r}{n}\right)^{nt} = Pe^{rt}.$$

- (b) With $P = \$5000$, $r = 0.02$, and $t = 10$ years,

$$A = 5000e^{0.02(10)} = 5000e^{0.2} \approx 6107.01,$$

so the investment is worth roughly $\boxed{\$6107.01}$ after 10 years.

- (c) With $P = \$10,000$ and $r = 0.024$, the investment will double to $\$20,000$ when t satisfies

$$20000 = 10000e^{0.024t} \quad \text{or} \quad e^{0.024t} = \frac{20000}{10000} = 2.$$

Thus, $0.024t = \ln 2$, or

$$t = \frac{1}{0.024} \ln 2 \approx \boxed{28.881 \text{ years}}.$$

- (d) With $A = Pe^{rt}$, then

$$\frac{dA}{dt} = Pe^{rt} \frac{d}{dt}(rt) = r(Pe^{rt}) = rA.$$

90. (a) With $P = \$2000$ and $r = 0.03$, $\boxed{A = 2000e^{0.03t}}$.

- (b) At maturity, $t = 10$ years, so

$$A = 2000e^{0.03(10)} = 2000e^{0.3} \approx 2699.72,$$

and the CD is worth roughly $\boxed{\$2699.72}$.

- (c) With $A = 2000e^{0.03t}$,

$$\frac{dA}{dt} = 2000e^{0.03t} \frac{d}{dt}(0.03t) = 60e^{0.03t}.$$

At $t = 3$, the rate of change of the amount A is

$$\frac{dA}{dt} = 60e^{0.03(3)} = 60e^{0.09} \approx 65.65,$$

or $\boxed{\text{roughly } \$65.65 \text{ per year}}$. At $t = 5$, the rate of change of the amount A is

$$\frac{dA}{dt} = 60e^{0.03(5)} = 60e^{0.15} \approx 69.71,$$

or $\boxed{\text{roughly } \$69.71 \text{ per year}}$. Finally, at $t = 8$, the rate of change of the amount A is

$$\frac{dA}{dt} = 60e^{0.03(8)} = 60e^{0.24} \approx 76.27,$$

or $\boxed{\text{roughly } \$76.27 \text{ per year}}$.

- (d) The rate at which the value of the CD increases is increasing in time. This is how compound interest works: interest is paid not only on the original deposit but also on any previously earned interest. Thus, as the value of the CD increases, the rate at which it increases also increases.

91. (a) With $I_0 = 10^{-12}$ and $I(x) = \frac{P}{4\pi x^2}$,

$$\begin{aligned} L(x) &= 10 \log \frac{I(x)}{I_0} = 10(\log I(x) - \log I_0) = 10 \left(\log \frac{P}{4\pi x^2} - \log I_0 \right) \\ &= 10 (\log P - \log(4\pi x^2) - \log I_0) \\ &= 10(\log P - \log(4\pi) - \log I_0) - 20 \log x. \end{aligned}$$

Thus

$$\frac{dL}{dx} = -\frac{20}{x \ln 10} \quad \text{and} \quad \frac{dL}{dx} = -\frac{20}{2 \ln 10} = \boxed{-\frac{10}{\ln 10} \frac{\text{dB}}{\text{m}}}.$$

- (b) The negative sign in the rate of change in part (a) indicates that the loudness of the sound decreases as the distance from the source of the sound increases.

92. Using the properties of the natural logarithm function, $\ln x + \ln y = \ln(xy)$. Thus,

$$\ln x + \ln y = 2x \quad \text{is equivalent to} \quad \ln(xy) = 2x,$$

and then exponentiating both sides of this last equation yields $xy = e^{2x}$, or

$$y = \frac{e^{2x}}{x}.$$

Thus,

$$y' = \frac{x \frac{d}{dx} e^{2x} - e^{2x} \frac{d}{dx} x}{x^2} = \frac{2xe^{2x} - e^{2x}}{x^2} = \frac{e^{2x}}{x} \cdot \frac{2x - 1}{x} = \boxed{\frac{y(2x - 1)}{x}},$$

which matches the derivative calculated in Example 1(c).

93. Let $\ln T = kt$, where k is a constant. Then

$$\begin{aligned} \frac{d}{dt} \ln T &= \frac{d}{dt}(kt) \\ \frac{1}{T} \frac{dT}{dt} &= k \\ \frac{dT}{dt} &= kT. \end{aligned}$$

94. The figure below displays a graph of $y = \left(1 + \frac{1}{x}\right)^x$ and a graph of $y = e$. The graph of $y = \left(1 + \frac{1}{x}\right)^x$ appears to have a horizontal asymptote of $y = e$, supporting the definition that

$$\lim_{n \rightarrow \infty} \left(1 + \frac{1}{n}\right)^n = e.$$

95. Let $y = |[u(x)]^a| = |u(x)|^a$. Then

$$\ln y = \ln |u(x)|^a = a \ln |u(x)|,$$

so that

$$\frac{d}{dx} \ln y = \frac{d}{dx} [a \ln |u(x)|] \quad \text{and} \quad \frac{1}{y} \frac{dy}{dx} = \frac{a}{u(x)} u'(x).$$

Thus,

$$\frac{dy}{dx} = \frac{a}{u(x)} u'(x) \cdot y = \frac{a}{u(x)} u'(x) |u(x)|^a,$$

or

$$\frac{d}{dx} |u(x)|^a = a \frac{|u(x)|^a}{u(x)} u'(x).$$

When $u(x) > 0$, $|u(x)|^a = [u(x)]^a$, and

$$\frac{d}{dx} [u(x)]^a = a \frac{[u(x)]^a}{u(x)} u'(x) = a [u(x)]^{a-1} u'(x).$$

On the other hand, when $u(x) < 0$, $|u(x)|^a = [-u(x)]^a = (-1)^a [u(x)]^a$, so

$$\frac{d}{dx} \{(-1)^a [u(x)]^a\} = a \frac{(-1)^a [u(x)]^a}{u(x)} u'(x) = (-1)^a a [u(x)]^{a-1} u'(x),$$

or

$$\frac{d}{dx} [u(x)]^a = a [u(x)]^{a-1} u'(x).$$

96. Let $f(x) = -\frac{1}{2}x^2 + k$ and $g(x) = \ln(bx) + c$, where $b > 0$ and k and c are constants. Then

$$f'(x) = -x \quad \text{and} \quad g'(x) = \frac{1}{bx} \cdot b = \frac{1}{x}.$$

Thus, for any fixed $x \neq 0$, the slope of the tangent line to the graph of f is the negative reciprocal of the slope of the tangent line to the graph of g ; in other words, the tangent lines to the graphs of the family of parabolas given by $f(x)$ are always perpendicular to the tangent lines to the graphs of the family of natural logarithms given by $g(x)$.

Challenge Problems

97. Let

$$f(x) = 2x - \ln(3 + 6e^x + 3e^{2x}) = 2x - \ln[3(1 + e^x)^2] = 2x - \ln 3 - 2\ln(1 + e^x)$$

and $g(x) = -2\ln(1 + e^{-x})$. First, note that both functions have a domain of all real numbers. Next,

$$f'(x) = 2 - \frac{2}{1 + e^x} \cdot e^x = \frac{2(1 + e^x) - 2e^x}{1 + e^x} = \frac{2}{1 + e^x}$$

and

$$g'(x) = -\frac{2}{1 + e^{-x}} \cdot (-e^{-x}) = \frac{2e^{-x}}{1 + e^{-x}} = \frac{2}{1 + e^x}.$$

Thus, $f'(x) = g'(x)$ for all real numbers x , so there exists a constant C such that $f(x) = g(x) + C$ for all real numbers x .

98. Let $f(x) > 0$ and $y = f(x)^{g(x)}$. Then

$$\ln y = g(x) \ln f(x),$$

so

$$\begin{aligned} \frac{d}{dx} \ln y &= \frac{d}{dx} [g(x) \ln f(x)] \\ \frac{1}{y} \frac{dy}{dx} &= g(x) \frac{1}{f(x)} \cdot f'(x) + g'(x) \ln f(x) \\ &= \frac{g(x)}{f(x)} f'(x) + g'(x) \ln f(x), \end{aligned}$$

and

$$\begin{aligned}\frac{d}{dx}f(x)^{g(x)} &= f(x)^{g(x)} \left(\frac{g(x)}{f(x)} f'(x) + g'(x) \ln f(x) \right) \\ &= g(x)f(x)^{g(x)-1}f'(x) + f(x)^{g(x)}g'(x)\ln f(x).\end{aligned}$$

3.4: Differentials; Linear Approximations; Newton's Method

Concepts and Vocabulary

1. If $y = f(x)$ is a differentiable function, the differential $dy = \boxed{(d) f'(x)dx}$.
2. A linear approximation of a differentiable function f near x_0 is given by the function

$$L(x) = \boxed{f(x_0) + f'(x_0) \cdot (x - x_0)}.$$

3. $\boxed{\text{True}}$. The difference $|\Delta y - dy|$ measures the departure of the graph of $y = f(x)$ from the graph of the tangent line to f .
4. If Q is a quantity to be measured and ΔQ is the error made in measuring Q , then the relative error in the measurement is given by the ratio

$$\boxed{\frac{|\Delta Q|}{Q(x_0)}}.$$

5. $\boxed{\text{True}}$. Newton's Method uses tangent lines to the graph of f to approximate the zeros of f .
6. $\boxed{\text{True}}$. Before using Newton's Method, we need a first approximation for the zero.

Skill Building

7. Let $y = f(x) = x^3 - 2x + 1$. Then

$$dy = f'(x) dx = \boxed{(3x^2 - 2) dx}.$$

8. Let $y = f(x) = e^x + 2x - 1$. Then

$$dy = f'(x) dx = \boxed{(e^x + 2) dx}.$$

9. Let $y = f(x) = 4(x^2 + 1)^{3/2}$. Then

$$f'(x) = 4 \cdot \frac{3}{2}(x^2 + 1)^{1/2} \frac{d}{dx}(x^2 + 1) = 6(x^2 + 1)^{1/2} \cdot 2x = 12x(x^2 + 1)^{1/2},$$

and

$$dy = f'(x) dx = \boxed{12x(x^2 + 1)^{1/2} dx}.$$

10. Let $y = f(x) = \sqrt{x^2 - 1}$. Then

$$f'(x) = \frac{1}{2}(x^2 - 1)^{-1/2} \frac{d}{dx}(x^2 - 1) = \frac{1}{2\sqrt{x^2 - 1}} \cdot 2x = \frac{x}{\sqrt{x^2 - 1}},$$

and

$$dy = f'(x) dx = \boxed{\frac{x}{\sqrt{x^2 - 1}} dx}.$$

11. Let $y = f(x) = 3 \sin(2x) + x$. Then

$$f'(x) = 3 \cos(2x) \frac{d}{dx}(2x) + 1 = 3 \cos(2x) \cdot 2 + 1 = 6 \cos(2x) + 1,$$

and

$$dy = f'(x) dx = \boxed{(6 \cos(2x) + 1) dx}.$$

12. Let $y = f(x) = \cos^2(3x) - x$. Then

$$\begin{aligned} f'(x) &= 2 \cos(3x) \frac{d}{dx} \cos(3x) - 1 = -2 \cos(3x) \sin(3x) \frac{d}{dx}(3x) - 1 \\ &= -2 \cos(3x) \sin(3x) \cdot 3 - 1 = -6 \cos(3x) \sin(3x) - 1, \end{aligned}$$

and

$$dy = f'(x) dx = \boxed{-(6 \cos(3x) \sin(3x) + 1) dx}.$$

13. Let $y = f(x) = e^{-x}$. Then

$$f'(x) = e^{-x} \frac{d}{dx}(-x) = -e^{-x},$$

and

$$dy = f'(x) dx = \boxed{-e^{-x} dx}.$$

14. Let $y = f(x) = e^{\sin x}$. Then

$$f'(x) = e^{\sin x} \frac{d}{dx} \sin x = \cos x e^{\sin x},$$

and

$$dy = f'(x) dx = \boxed{\cos x e^{\sin x} dx}.$$

15. Let $y = f(x) = xe^x$. Then

$$f'(x) = x \frac{d}{dx} e^x + e^x \frac{d}{dx} x = xe^x + e^x,$$

and

$$dy = f'(x) dx = \boxed{(xe^x + e^x) dx}.$$

16. Let $y = f(x) = \frac{e^{-x}}{x}$. Then

$$f'(x) = \frac{x \frac{d}{dx} e^{-x} - e^{-x} \frac{d}{dx} x}{x^2} = \frac{xe^{-x} \frac{d}{dx}(-x) - e^{-x}}{x^2} = -\frac{e^{-x}(x+1)}{x^2},$$

and

$$dy = f'(x) dx = \boxed{-\frac{e^{-x}(x+1)}{x^2} dx}.$$

17. Let $f(x) = e^x$.

(a) $dy = f'(x) dx = \boxed{e^x dx}.$

(b) i. With $x = 1$ and $\Delta x = dx = 0.5$,

$$dy = e^1(0.5) = \boxed{\frac{1}{2}e \approx 1.359141},$$

and

$$\Delta y = f(1 + 0.5) - f(1) = \boxed{e^{1.5} - e \approx 1.763407}.$$

ii. With $x = 1$ and $\Delta x = dx = 0.1$,

$$dy = e^1(0.1) = \boxed{\frac{1}{10}e \approx 0.271828},$$

and

$$\Delta y = f(1 + 0.1) - f(1) = \boxed{e^{1.1} - e \approx 0.285884}.$$

iii. With $x = 1$ and $\Delta x = dx = 0.01$,

$$dy = e^1(0.01) = \boxed{\frac{1}{100}e \approx 0.027183},$$

and

$$\Delta y = f(1 + 0.01) - f(1) = \boxed{e^{1.01} - e \approx 0.027319}.$$

(c) i. With $x = 1$ and $\Delta x = dx = 0.5$,

$$|\Delta y - dy| \approx \boxed{|1.763407 - 1.359141| = 0.404266}.$$

ii. With $x = 1$ and $\Delta x = dx = 0.1$,

$$|\Delta y - dy| \approx \boxed{|0.285884 - 0.271828| = 0.014056}.$$

iii. With $x = 1$ and $\Delta x = dx = 0.01$,

$$|\Delta y - dy| \approx \boxed{|0.027319 - 0.027183| = 0.000136}.$$

18. Let $f(x) = e^{-x}$.

(a) $dy = f'(x) dx = \boxed{-e^{-x} dx}.$

(b) i. With $x = 1$ and $\Delta x = dx = 0.5$,

$$dy = -e^{-1}(0.5) = \boxed{-\frac{1}{2e} \approx -0.183940},$$

and

$$\Delta y = f(1 + 0.5) - f(1) = \boxed{e^{-1.5} - e^{-1} \approx -0.144749}.$$

ii. With $x = 1$ and $\Delta x = dx = 0.1$,

$$dy = -e^{-1}(0.1) = \boxed{-\frac{1}{10e} \approx -0.036788},$$

and

$$\Delta y = f(1 + 0.1) - f(1) = \boxed{e^{-1.1} - e^{-1} \approx -0.035008}.$$

iii. With $x = 1$ and $\Delta x = dx = 0.01$,

$$dy = -e^{-1}(0.01) = \boxed{-\frac{1}{100e} \approx -0.003679},$$

and

$$\Delta y = f(1 + 0.01) - f(1) = \boxed{e^{-1.01} - e^{-1} \approx -0.003660}.$$

(c) i. With $x = 1$ and $\Delta x = dx = 0.5$,

$$|\Delta y - dy| \approx \boxed{|-0.144749 - (-0.183940)| = 0.039191}.$$

ii. With $x = 1$ and $\Delta x = dx = 0.1$,

$$|\Delta y - dy| \approx \boxed{|-0.035008 - (-0.036788)| = 0.001780}.$$

iii. With $x = 1$ and $\Delta x = dx = 0.01$,

$$|\Delta y - dy| \approx \boxed{|-0.003660 - (-0.003679)| = 0.000019}.$$

19. Let $f(x) = x^{2/3}$.

$$(a) \quad dy = f'(x) dx = \frac{2}{3} x^{-1/3} dx = \boxed{\frac{2}{3\sqrt[3]{x}} dx}.$$

(b) i. With $x = 2$ and $\Delta x = dx = 0.5$,

$$dy = \frac{2}{3\sqrt[3]{2}}(0.5) \approx 0.264567,$$

and

$$\Delta y = f(2 + 0.5) - f(2) = \boxed{(2.5)^{2/3} - 2^{2/3} \approx 0.254615}.$$

ii. With $x = 2$ and $\Delta x = dx = 0.1$,

$$dy = \frac{2}{3\sqrt[3]{2}}(0.1) \approx 0.052913,$$

and

$$\Delta y = f(2 + 0.1) - f(2) = \boxed{(2.1)^{2/3} - 2^{2/3} \approx 0.052482}.$$

iii. With $x = 2$ and $\Delta x = dx = 0.01$,

$$dy = \frac{2}{3\sqrt[3]{2}}(0.01) \approx 0.005291,$$

and

$$\Delta y = f(2 + 0.01) - f(2) = \boxed{(2.01)^{2/3} - 2^{2/3} \approx 0.005287}.$$

(c) i. With $x = 2$ and $\Delta x = dx = 0.5$,

$$|\Delta y - dy| \approx \boxed{|0.254615 - 0.264567| = 0.009952}.$$

ii. With $x = 2$ and $\Delta x = dx = 0.1$,

$$|\Delta y - dy| \approx \boxed{|0.052482 - 0.052913| = 0.000431}.$$

iii. With $x = 2$ and $\Delta x = dx = 0.01$,

$$|\Delta y - dy| \approx \boxed{|0.005287 - 0.005291| = 0.000004 = 4 \times 10^{-6}}.$$

20. Let $f(x) = x^{-1/2}$.

$$(a) \quad dy = f'(x) dx = \boxed{-\frac{1}{2} x^{-3/2} dx}.$$

(b) i. With $x = 1$ and $\Delta x = dx = 0.5$,

$$dy = -\frac{1}{2} 1^{-3/2}(0.5) = \boxed{-\frac{1}{4} = -0.25},$$

and

$$\Delta y = f(1 + 0.5) - f(1) = \boxed{(1.5)^{-1/2} - 1 \approx -0.183503}.$$

ii. With $x = 1$ and $\Delta x = dx = 0.1$,

$$dy = -\frac{1}{2}1^{-3/2}(0.1) = \boxed{-\frac{1}{20} = -0.05},$$

and

$$\Delta y = f(1 + 0.1) - f(1) = \boxed{(1.1)^{-1/2} - 1 \approx -0.046537}.$$

iii. With $x = 1$ and $\Delta x = dx = 0.01$,

$$dy = -\frac{1}{2}1^{-3/2}(0.01) = \boxed{-\frac{1}{200} = -0.005},$$

and

$$\Delta y = f(1 + 0.01) - f(1) = \boxed{(1.01)^{-1/2} - 1 \approx -0.004963}.$$

(c) i. With $x = 1$ and $\Delta x = dx = 0.5$,

$$|\Delta y - dy| \approx \boxed{|-0.183503 - (-0.25)| = 0.066497}.$$

ii. With $x = 1$ and $\Delta x = dx = 0.1$,

$$|\Delta y - dy| \approx \boxed{|-0.046537 - (-0.05)| = 0.003463}.$$

iii. With $x = 1$ and $\Delta x = dx = 0.01$,

$$|\Delta y - dy| \approx \boxed{|-0.004963 - (-0.005)| = 0.000037}.$$

21. Let $f(x) = \cos x$.

(a) $dy = f'(x) dx = \boxed{-\sin x dx}.$

(b) i. With $x = \pi$ and $\Delta x = dx = 0.5$,

$$dy = -\sin \pi(0.5) = \boxed{0},$$

and

$$\Delta y = f(\pi + 0.5) - f(\pi) = \boxed{\cos(\pi + 0.5) - \cos(\pi) \approx 0.122417}.$$

ii. With $x = \pi$ and $\Delta x = dx = 0.1$,

$$dy = -\sin \pi(0.1) = \boxed{0},$$

and

$$\Delta y = f(\pi + 0.1) - f(\pi) = \boxed{\cos(\pi + 0.1) - \cos \pi \approx 0.004996}.$$

iii. With $x = \pi$ and $\Delta x = dx = 0.01$,

$$dy = -\sin \pi(0.01) = \boxed{0},$$

and

$$\Delta y = f(\pi + 0.01) - f(\pi) = \boxed{\cos(\pi + 0.01) - \cos \pi \approx 0.000050}.$$

(c) i. With $x = \pi$ and $\Delta x = dx = 0.5$,

$$|\Delta y - dy| \approx \boxed{|0.122417 - 0| = 0.122417}.$$

- ii. With $x = \pi$ and $\Delta x = dx = 0.1$,

$$|\Delta y - dy| \approx \boxed{|0.004996 - 0| = 0.004996}.$$

- iii. With $x = \pi$ and $\Delta x = dx = 0.01$,

$$|\Delta y - dy| \approx \boxed{|0.000050 - 0| = 0.000050}.$$

22. Let $f(x) = \tan x$.

(a) $dy = f'(x) dx = \boxed{\sec^2 x dx}$.

- (b) i. With $x = 0$ and $\Delta x = dx = 0.5$,

$$dy = \sec^2 0(0.5) = \boxed{0.5},$$

and

$$\Delta y = f(0 + 0.5) - f(0) = \boxed{\tan 0.5 - \tan 0 \approx 0.546302}.$$

- ii. With $x = 0$ and $\Delta x = dx = 0.1$,

$$dy = \sec^2 0(0.1) = \boxed{0.1},$$

and

$$\Delta y = f(0 + 0.1) - f(0) = \boxed{\tan 0.1 - \tan 0 \approx 0.100335}.$$

- iii. With $x = 0$ and $\Delta x = dx = 0.01$,

$$dy = \sec^2 0(0.01) = \boxed{0.01},$$

and

$$\Delta y = f(0 + 0.01) - f(0) = \boxed{\tan 0.01 - \tan 0 \approx 0.010000333}.$$

- (c) i. With $x = 0$ and $\Delta x = dx = 0.5$,

$$|\Delta y - dy| \approx \boxed{|0.546302 - 0.5| = 0.046302}.$$

- ii. With $x = 0$ and $\Delta x = dx = 0.1$,

$$|\Delta y - dy| \approx \boxed{|0.100335 - 0.1| = 0.000335}.$$

- iii. With $x = 0$ and $\Delta x = dx = 0.01$,

$$|\Delta y - dy| \approx \boxed{|0.010000333 - 0.01| = 3.33 \times 10^{-7}}.$$

23. (a) Let $f(x) = (x + 1)^5$ and $x_0 = 2$. Then $f(x_0) = f(2) = 3^5 = 243$, $f'(x) = 5(x + 1)^4$, $f'(x_0) = f'(2) = 5(3)^4 = 405$, and

$$L(x) = f(x_0) + f'(x_0)(x - x_0) = 243 + 405(x - 2) = \boxed{405x - 567}.$$

- (b) The figure below displays the graph of f as the solid curve and the graph of L as the dashed curve.

24. (a) Let $f(x) = x^3 - 1$ and $x_0 = 0$. Then $f(x_0) = f(0) = -1$, $f'(x) = 3x^2$, $f'(x_0) = f'(0) = 0$, and

$$L(x) = f(x_0) + f'(x_0)(x - x_0) = -1 + 0(x - 0) = \boxed{-1}.$$

- (b) The figure below displays the graph of f as the solid curve and the graph of L as the dashed curve.

25. (a) Let $f(x) = \sqrt{x}$ and $x_0 = 4$. Then $f(x_0) = f(4) = 2$, $f'(x) = \frac{1}{2\sqrt{x}}$, $f'(x_0) = f'(4) = \frac{1}{4}$, and

$$L(x) = f(x_0) + f'(x_0)(x - x_0) = 2 + \frac{1}{4}(x - 4) = \boxed{\frac{1}{4}x + 1}.$$

- (b) The figure below displays the graph of f as the solid curve and the graph of L as the dashed curve.

26. (a) Let $f(x) = x^{2/3}$ and $x_0 = 1$. Then $f(x_0) = f(1) = 1$, $f'(x) = \frac{2}{3}x^{-1/3}$, $f'(x_0) = f'(1) = \frac{2}{3}$, and

$$L(x) = f(x_0) + f'(x_0)(x - x_0) = 1 + \frac{2}{3}(x - 1) = \boxed{\frac{2}{3}x + \frac{1}{3}}.$$

- (b) The figure below displays the graph of f as the solid curve and the graph of L as the dashed curve.

27. (a) Let $f(x) = \ln x$ and $x_0 = 1$. Then $f(x_0) = f(1) = 0$, $f'(x) = \frac{1}{x}$, $f'(x_0) = f'(1) = 1$, and

$$L(x) = f(x_0) + f'(x_0)(x - x_0) = 0 + 1(x - 1) = \boxed{x - 1}.$$

- (b) The figure below displays the graph of f as the solid curve and the graph of L as the dashed curve.

28. (a) Let $f(x) = e^x$ and $x_0 = 1$. Then $f(x_0) = f(1) = e$, $f'(x) = e^x$, $f'(x_0) = f'(1) = e$, and

$$L(x) = f(x_0) + f'(x_0)(x - x_0) = e + e(x - 1) = \boxed{ex}.$$

- (b) The figure below displays the graph of f as the solid curve and the graph of L as the dashed curve.

29. (a) Let $f(x) = \cos x$ and $x_0 = \frac{\pi}{3}$. Then $f(x_0) = f\left(\frac{\pi}{3}\right) = \frac{1}{2}$, $f'(x) = -\sin x$,

$$f'(x_0) = f'\left(\frac{\pi}{3}\right) = -\frac{\sqrt{3}}{2}, \text{ and}$$

$$L(x) = f(x_0) + f'(x_0)(x - x_0) = \frac{1}{2} - \frac{\sqrt{3}}{2} \left(x - \frac{\pi}{3}\right) = \boxed{-\frac{\sqrt{3}}{2}x + \frac{1}{2} + \frac{\pi\sqrt{3}}{6}}.$$

- (b) The figure below displays the graph of f as the solid curve and the graph of L as the dashed curve.

30. (a) Let $f(x) = \sin x$ and $x_0 = \frac{\pi}{6}$. Then $f(x_0) = f\left(\frac{\pi}{6}\right) = \frac{1}{2}$, $f'(x) = \cos x$, $f'(x_0) = f'\left(\frac{\pi}{6}\right) = \frac{\sqrt{3}}{2}$, and

$$L(x) = f(x_0) + f'(x_0)(x - x_0) = \frac{1}{2} + \frac{\sqrt{3}}{2} \left(x - \frac{\pi}{6}\right) = \boxed{\frac{\sqrt{3}}{2}x + \frac{1}{2} - \frac{\pi\sqrt{3}}{12}}.$$

- (b) The figure below displays the graph of f as the solid curve and the graph of L as the dashed curve.

31. (a) Let $f(x) = x^2$ and $\Delta x = dx = 3.001 - 3 = 0.001$. Then $f'(x) = 2x$ and

$$\Delta y \approx dy = f'(3) dx = 6(0.001) = \boxed{0.006}.$$

- (b) Let $f(x) = \frac{1}{x+2}$ and $\Delta x = dx = 1.98 - 2 = -0.02$. Then $f'(x) = -\frac{1}{(x+2)^2}$ and

$$\Delta y \approx dy = f'(2) dx = -\frac{1}{16}(-0.02) = \boxed{0.00125}.$$

32. (a) Let $f(x) = x^3$ and $\Delta x = dx = 3.01 - 3 = 0.01$. Then $f'(x) = 3x^2$ and

$$\Delta y \approx dy = f'(3) dx = 27(0.01) = \boxed{0.27}.$$

- (b) Let $f(x) = \frac{1}{x-1}$ and $\Delta x = dx = 1.98 - 2 = -0.02$. Then $f'(x) = -\frac{1}{(x-1)^2}$ and

$$\Delta y \approx dy = f'(2) dx = -\frac{1}{1}(-0.02) = \boxed{0.02}.$$

33. (a) Let $f(x) = x^3 + 3x - 5$. Being a polynomial function, f is continuous on the set of all real numbers, so it is continuous on the closed interval $[1, 2]$. Because $f(1) = 1 + 3 - 5 = -1 < 0$ and $f(2) = 2^3 + 3(2) - 5 = 9 > 0$, the Intermediate Value Theorem guarantees that f has a zero on the interval $(1, 2)$.

- (b) With $f(x) = x^3 + 3x - 5$, $f'(x) = 3x^2 + 3$. Let $c_1 = 1.5$. Then

$$c_2 = c_1 - \frac{f(c_1)}{f'(c_1)} = 1.5 - \frac{f(1.5)}{f'(1.5)} = 1.5 - \frac{2.875}{9.75} \approx 1.205128.$$

Next, $f(c_2) \approx 0.365632$ and $f'(c_2) \approx 7.357000$, so

$$c_3 = c_2 - \frac{f(c_2)}{f'(c_2)} \approx 1.205128 - \frac{0.365632}{7.357000} \approx \boxed{1.155429}.$$

34. (a) Let $f(x) = x^3 - 4x + 2$. Being a polynomial function, f is continuous on the set of all real numbers, so it is continuous on the closed interval $[1, 2]$. Because $f(1) = 1 - 4 + 2 = -1 < 0$ and $f(2) = 2^3 - 4(2) + 2 = 2 > 0$, the Intermediate Value Theorem guarantees that f has a zero on the interval $(1, 2)$.

- (b) With $f(x) = x^3 - 4x + 2$, $f'(x) = 3x^2 - 4$. Let $c_1 = 1.5$. Then

$$c_2 = c_1 - \frac{f(c_1)}{f'(c_1)} = 1.5 - \frac{f(1.5)}{f'(1.5)} = 1.5 - \frac{-0.625}{2.75} \approx 1.727273.$$

Next, $f(c_2) \approx 0.244179$ and $f'(c_2) \approx 4.950416$, so

$$c_3 = c_2 - \frac{f(c_2)}{f'(c_2)} \approx 1.727273 - \frac{0.244179}{4.950416} \approx \boxed{1.677948}.$$

35. (a) Let $f(x) = 2x^3 + 3x^2 + 4x - 1$. Being a polynomial function, f is continuous on the set of all real numbers, so it is continuous on the closed interval $[0, 1]$. Because $f(0) = -1 < 0$ and $f(1) = 2 + 3 + 4 - 1 = 8 > 0$, the Intermediate Value Theorem guarantees that f has a zero on the interval $(0, 1)$.

- (b) With $f(x) = 2x^3 + 3x^2 + 4x - 1$, $f'(x) = 6x^2 + 6x + 4$. Let $c_1 = 0.5$. Then

$$c_2 = c_1 - \frac{f(c_1)}{f'(c_1)} = 0.5 - \frac{f(0.5)}{f'(0.5)} = 0.5 - \frac{2}{8.5} \approx 0.264706.$$

Next, $f(c_2) \approx 0.306127$ and $f'(c_2) \approx 6.008652$, so

$$c_3 = c_2 - \frac{f(c_2)}{f'(c_2)} \approx 0.264706 - \frac{0.306127}{6.008652} \approx \boxed{0.213758}.$$

36. (a) Let $f(x) = x^3 - x^2 - 2x + 1$. Being a polynomial function, f is continuous on the set of all real numbers, so it is continuous on the closed interval $[0, 1]$. Because $f(0) = 1 > 0$ and $f(1) = 1 - 1 - 2 + 1 = -1 < 0$, the Intermediate Value Theorem guarantees that f has a zero on the interval $(0, 1)$.

- (b) With $f(x) = x^3 - x^2 - 2x + 1$, $f'(x) = 3x^2 - 2x - 2$. Let $c_1 = 0.5$. Then

$$c_2 = c_1 - \frac{f(c_1)}{f'(c_1)} = 0.5 - \frac{f(0.5)}{f'(0.5)} = 0.5 - \frac{-0.125}{-2.25} \approx 0.444444.$$

Next, $f(c_2) \approx 0.001373$ and $f'(c_2) \approx -2.296297$, so

$$c_3 = c_2 - \frac{f(c_2)}{f'(c_2)} \approx 0.444444 - \frac{0.001373}{-2.296297} \approx \boxed{0.445042}.$$

37. (a) Let $f(x) = x^3 - 6x - 12$. Being a polynomial function, f is continuous on the set of all real numbers, so it is continuous on the closed interval $[3, 4]$. Because $f(3) = 3^3 - 6(3) - 12 = -3 < 0$ and $f(4) = 4^3 - 6(4) - 12 = 28 > 0$, the Intermediate Value Theorem guarantees that f has a zero on the interval $(3, 4)$.

- (b) With $f(x) = x^3 - 6x - 12$, $f'(x) = 3x^2 - 6$. Let $c_1 = 3.5$. Then

$$c_2 = c_1 - \frac{f(c_1)}{f'(c_1)} = 3.5 - \frac{f(3.5)}{f'(3.5)} = 3.5 - \frac{9.875}{30.75} \approx 3.178862.$$

Next, $f(c_2) \approx 1.049749$ and $f'(c_2) \approx 24.315491$, so

$$c_3 = c_2 - \frac{f(c_2)}{f'(c_2)} \approx 3.178862 - \frac{1.049749}{24.315491} \approx \boxed{3.135690}.$$

38. (a) Let $f(x) = 3x^3 + 5x - 40$. Being a polynomial function, f is continuous on the set of all real numbers, so it is continuous on the closed interval $[2, 3]$. Because $f(2) = 3(2)^3 + 5(2) - 40 = -6 < 0$ and $f(3) = 3(3)^3 + 5(3) - 40 = 56 > 0$, the Intermediate Value Theorem guarantees that f has a zero on the interval $(2, 3)$.

- (b) With $f(x) = 3x^3 + 5x - 40$, $f'(x) = 9x^2 + 5$. Let $c_1 = 2.5$. Then

$$c_2 = c_1 - \frac{f(c_1)}{f'(c_1)} = 2.5 - \frac{f(2.5)}{f'(2.5)} = 2.5 - \frac{19.375}{61.25} \approx 2.183673.$$

Next, $f(c_2) \approx 2.156426$ and $f'(c_2) \approx 47.915850$, so

$$c_3 = c_2 - \frac{f(c_2)}{f'(c_2)} \approx 2.183673 - \frac{2.156426}{47.915850} \approx \boxed{2.138669}.$$

39. (a) Let $f(x) = x^4 - 2x^3 + 21x - 23$. Being a polynomial function, f is continuous on the set of all real numbers, so it is continuous on the closed interval $[1, 2]$. Because $f(1) = 1 - 2 + 21 - 23 = -3 < 0$ and $f(2) = 2^4 - 2(2)^3 + 21(2) - 23 = 19 > 0$, the Intermediate Value Theorem guarantees that f has a zero on the interval $(1, 2)$.

- (b) Answers will vary. Using the midpoint of the interval $(1, 2)$ as the first approximation c_1 yields the following results. With $f(x) = x^4 - 2x^3 + 21x - 23$, $f'(x) = 4x^3 - 6x^2 + 21$. Let $c_1 = 1.5$. Then

$$c_2 = c_1 - \frac{f(c_1)}{f'(c_1)} = 1.5 - \frac{f(1.5)}{f'(1.5)} = 1.5 - \frac{6.8125}{21} \approx 1.175595.$$

Next, $f(c_2) \approx 0.348084$ and $f'(c_2) \approx 19.206659$, so

$$c_3 = c_2 - \frac{f(c_2)}{f'(c_2)} \approx 1.175595 - \frac{0.348084}{19.206659} \approx \boxed{1.157472}.$$

40. (a) Let $f(x) = x^4 - x^3 + x - 2$. Being a polynomial function, f is continuous on the set of all real numbers, so it is continuous on the closed interval $[1, 2]$. Because $f(1) = 1 - 1 + 1 - 2 = -1 < 0$ and $f(2) = 2^4 - 2^3 + 2 - 2 = 8 > 0$, the Intermediate Value Theorem guarantees that f has a zero on the interval $(1, 2)$.

- (b) Answers will vary. Using the midpoint of the interval $(1, 2)$ as the first approximation c_1 yields the following results. With $f(x) = x^4 - x^3 + x - 2$, $f'(x) = 4x^3 - 3x^2 + 1$. Let $c_1 = 1.5$. Then

$$c_2 = c_1 - \frac{f(c_1)}{f'(c_1)} = 1.5 - \frac{f(1.5)}{f'(1.5)} = 1.5 - \frac{1.1875}{7.75} \approx 1.346774.$$

Next, $f(c_2) \approx 0.193866$ and $f'(c_2) \approx 5.329715$, so

$$c_3 = c_2 - \frac{f(c_2)}{f'(c_2)} \approx 1.346774 - \frac{0.193866}{5.329715} \approx \boxed{1.310399}.$$

41. (a) Let $f(x) = x + e^x$. The function f is continuous on the set of all real numbers, so it is continuous on the closed interval $[-1, 0]$. Because $f(-1) = -1 + e^{-1} \approx -0.632 < 0$ and $f(0) = 1 > 0$, the Intermediate Value Theorem guarantees that f has a zero on the interval $(-1, 0)$.
- (b) Begin by calculating $f'(x) = 1 + e^x$. Then, using a TI-84 Plus graphing calculator with $c_1 = -0.5$ yields

$$\begin{aligned} c_2 &= c_1 - \frac{f(c_1)}{f'(c_1)} \approx -0.5663110032; \\ c_3 &= c_2 - \frac{f(c_2)}{f'(c_2)} \approx -0.5671431650; \\ c_4 &= c_3 - \frac{f(c_3)}{f'(c_3)} \approx -0.5671432904; \text{ and} \\ c_5 &= c_4 - \frac{f(c_4)}{f'(c_4)} \approx \boxed{-0.5671432904}. \end{aligned}$$

42. (a) Let $f(x) = x - e^{-x}$. The function f is continuous on the set of all real numbers, so it is continuous on the closed interval $[0, 1]$. Because $f(0) = -1 < 0$ and $f(1) = 1 - e^{-1} \approx 0.632 > 0$, the Intermediate Value Theorem guarantees that f has a zero on the interval $(0, 1)$.
- (b) Begin by calculating $f'(x) = 1 + e^{-x}$. Then, using a TI-84 Plus graphing calculator with $c_1 = 0.5$ yields

$$\begin{aligned} c_2 &= c_1 - \frac{f(c_1)}{f'(c_1)} \approx 0.5663110032; \\ c_3 &= c_2 - \frac{f(c_2)}{f'(c_2)} \approx 0.5671431650; \\ c_4 &= c_3 - \frac{f(c_3)}{f'(c_3)} \approx 0.5671432904; \text{ and} \\ c_5 &= c_4 - \frac{f(c_4)}{f'(c_4)} \approx \boxed{0.5671432904}. \end{aligned}$$

43. (a) Let $f(x) = x^3 + \cos^2 x$. The function f is continuous on the set of all real numbers, so it is continuous on the closed interval $[-1, 0]$. Because $f(-1) = -1 + \cos^2(-1) \approx -0.708 < 0$ and $f(0) = 1 > 0$, the Intermediate Value Theorem guarantees that f has a zero on the interval $(-1, 0)$.
- (b) Begin by calculating

$$f'(x) = 3x^2 + 2 \cos x \frac{d}{dx} \cos x = 3x^2 - 2 \sin x \cos x.$$

Then, using a TI-84 Plus graphing calculator with $c_1 = -0.5$ yields

$$\begin{aligned} c_2 &= c_1 - \frac{f(c_1)}{f'(c_1)} \approx -0.9053804053; \\ c_3 &= c_2 - \frac{f(c_2)}{f'(c_2)} \approx -0.8001514047; \\ c_4 &= c_3 - \frac{f(c_3)}{f'(c_3)} \approx -0.7908914208; \text{ and} \\ c_5 &= c_4 - \frac{f(c_4)}{f'(c_4)} \approx \boxed{-0.7908208349}. \end{aligned}$$

44. (a) Let $f(x) = x^2 + 2 \sin x - 0.5$. The function f is continuous on the set of all real numbers, so it is continuous on the closed interval $[0, 1]$. Because $f(0) = -0.5 < 0$ and $f(1) = 1 + 2 \sin 1 - 0.5 \approx 2.183 > 0$, the Intermediate Value Theorem guarantees that f has a zero on the interval $(0, 1)$.

- (b) Begin by calculating $f'(x) = 2x + 2\cos x$. Then, using a TI-84 Plus graphing calculator with $c_1 = 0.5$ yields

$$\begin{aligned}c_2 &= c_1 - \frac{f(c_1)}{f'(c_1)} \approx 0.2427192037; \\c_3 &= c_2 - \frac{f(c_2)}{f'(c_2)} \approx 0.2264020798; \\c_4 &= c_3 - \frac{f(c_3)}{f'(c_3)} \approx 0.2263172819; \text{ and} \\c_5 &= c_4 - \frac{f(c_4)}{f'(c_4)} \approx \boxed{0.2263172795}.\end{aligned}$$

45. (a) Let $f(x) = 5 - \sqrt{x^2 + 2}$. The function f is continuous on the set of all real numbers, so it is continuous on the closed interval $[4, 5]$. Because $f(4) = 5 - \sqrt{18} \approx 0.757 > 0$ and $f(5) = 5 - \sqrt{27} \approx -0.196 < 0$, the Intermediate Value Theorem guarantees that f has a zero on the interval $(4, 5)$.

- (b) Begin by calculating

$$f'(x) = -\frac{1}{2}(x^2 + 2)^{-1/2} \frac{d}{dx}(x^2 + 2) = -\frac{1}{2}(x^2 + 2)^{-1/2} \cdot 2x = -\frac{x}{\sqrt{x^2 + 2}}.$$

Then, using a TI-84 Plus graphing calculator with $c_1 = 4.5$ yields

$$\begin{aligned}c_2 &= c_1 - \frac{f(c_1)}{f'(c_1)} \approx 4.796656184; \\c_3 &= c_2 - \frac{f(c_2)}{f'(c_2)} \approx 4.795831529; \\c_4 &= c_3 - \frac{f(c_3)}{f'(c_3)} \approx 4.795831524; \text{ and} \\c_5 &= c_4 - \frac{f(c_4)}{f'(c_4)} \approx \boxed{4.795831523}.\end{aligned}$$

46. (a) Let $f(x) = 2x^2 + x^{2/3} - 4$. The function f is continuous on the set of all real numbers, so it is continuous on the closed interval $[1, 2]$. Because $f(1) = 2 + 1 - 4 = -1 < 0$ and $f(2) = 8 - 2^{2/3} - 4 \approx 2.413 > 0$, the Intermediate Value Theorem guarantees that f has a zero on the interval $(1, 2)$.

- (b) Begin by calculating $f'(x) = 4x + \frac{2}{3}x^{-1/3}$. Then, using a TI-84 Plus graphing calculator with $c_1 = 1.5$ yields

$$\begin{aligned}c_2 &= c_1 - \frac{f(c_1)}{f'(c_1)} \approx 1.224967447; \\c_3 &= c_2 - \frac{f(c_2)}{f'(c_2)} \approx 1.198542475; \\c_4 &= c_3 - \frac{f(c_3)}{f'(c_3)} \approx 1.198295916; \text{ and} \\c_5 &= c_4 - \frac{f(c_4)}{f'(c_4)} \approx \boxed{1.198295895}.\end{aligned}$$

47. The formula for the area of a circle is $A = \pi R^2$, where R is the radius of the circle. With $\Delta R = dR = 10.1 - 10 = 0.1$ cm, the approximate increase in the area of the top surface is

$$\Delta A \approx dA = 2\pi R dR = 2\pi(10)(0.1) = \boxed{2\pi \text{ cm}^2}.$$

48. The volume V of a circular cylinder with a height of 3 cm and a radius r is $V = \pi r^2 h = 3\pi r^2$. With $\Delta r = dr = 2.2 - 2 = 0.2$ cm, the approximate volume of wood removed is

$$\Delta V \approx dV = 6\pi r dr = 6\pi(2)(0.2) = \boxed{2.4\pi \text{ cm}^3}.$$

49. The volume V of a sphere of radius r is $V = \frac{4}{3}\pi r^3$. With $\Delta r = dr = 3.1 - 3 = 0.1$ m, the approximate change in the volume of the balloon is

$$\Delta V \approx dV = 4\pi r^2 dr = 4\pi(3)^2(0.1) = \boxed{3.6\pi \text{ m}^3}.$$

50. The volume V of a right circular cone with a height h equal to four times its radius r is $V = \frac{1}{3}\pi r^2 h = \frac{1}{3}\pi r^2(4r) = \frac{4}{3}\pi r^3$. With $\Delta r = dr = 1.9 - 2 = -0.1$ cm, the approximate change in volume of the cup is

$$\Delta V \approx dV = 4\pi r^2 dr = 4\pi(2)^2(-0.1) = -1.6\pi \text{ cm}^3 \approx -5.0 \text{ cm}^3.$$

The approximate loss in capacity of the cup is $\boxed{5.0 \text{ cm}^3}$.

51. (a) The volume V of a sphere of radius r is $V = \frac{4}{3}\pi r^3$. With $\Delta r = dr = 2.1 - 2 = 0.1$ m, the approximate volume of material needed for the specified hollow sphere is

$$\Delta V \approx dV = 4\pi r^2 dr = 4\pi(2)^2(0.1) = \boxed{1.6\pi \text{ m}^3} \approx 5.0 \text{ m}^3.$$

- (b) The actual amount of material needed for the specified hollow sphere is

$$\Delta V = V(2.1) - V(2) = \frac{4}{3}\pi(2.1)^3 - \frac{4}{3}\pi(2)^3 \approx 5.3 \text{ m}^3.$$

The approximation using differentials $\boxed{\text{underestimates}}$ the amount of material needed.

- (c) Answers will vary. One possible response is that knowing the approximation using differentials underestimates the actual material needed, the manufacturer will know to adjust upward the amount of material needed to complete the order for 10,000 spheres so as not to run out before the order has been filled.
52. (a) The difference in the distances traveled by the bugs is the difference between the circumference of a circle with a radius of 7 cm (the ant) and the circumference of a circle with a radius of 9 cm (the bee). The circumference C of a circle of radius r is $C = 2\pi r$. With $\Delta r = dr = 9 - 7 = 2$ cm, the approximate difference in the distances traveled by the two bugs is

$$\Delta C \approx dC = 2\pi dr = 2\pi(2) = \boxed{4\pi \text{ cm}}.$$

- (b) The actual difference in the distances traveled by the two bugs is

$$\Delta C = C(9) - C(7) = 2\pi(9) - 2\pi(7) = 4\pi \text{ cm}.$$

The linear approximation $\boxed{\text{neither underestimates nor overestimates}}$ the difference in the distances traveled. The linear approximation provides the exact value for the difference because the circumference of a circle is a linear function of the radius of the circle.

53. Let h denote the height of the building and x denote the length of the shadow of the 3-meter pole. Applying similar triangles to the figure in the text yields

$$\frac{h}{9+x} = \frac{3}{x} \quad \text{or} \quad h = \frac{27+3x}{x} = \frac{27}{x} + 3.$$

When $x = 1$ meter, the height of the building is calculated to be

$$h = \frac{27}{1} + 3 = 30 \text{ meters.}$$

Because the percentage error in the measurement of the length of the shadow of the 3-meter pole is 1%,

$$\frac{|\Delta x|}{x} = \frac{|dx|}{x} = 0.01,$$

so $|dx| = 0.01(1) = 0.01$, or $dx = \pm 0.01$. Using differentials, it then follows that

$$\Delta h \approx dh = -\frac{27}{x^2} dx = -\frac{27}{1^2} (\pm 0.01) = \pm 0.27 \text{ meters.}$$

Therefore, the height of the building is $\boxed{30 \pm 0.27 \text{ meters}}$. The percentage error in the estimate for the height of the building is

$$\frac{|\Delta h|}{h} \times 100\% \approx \frac{|\pm 0.27|}{30} \times 100\% = \boxed{0.9\%}.$$

54. Let $T = 2\pi\sqrt{\frac{l}{g}}$. The change in the period of the pendulum as a result of a change in the length of the pendulum is then

$$\Delta T \approx dT = \frac{2\pi}{\sqrt{g}} \cdot \frac{1}{2\sqrt{l}} dl = \frac{\pi}{\sqrt{gl}} dl,$$

so

$$\frac{|\Delta T|}{T} \approx \frac{|dT|}{T} = \frac{\pi/\sqrt{gl}}{2\pi\sqrt{l/g}} |dl| = \frac{1}{2} \cdot \frac{|dl|}{l}.$$

Because the length of the pendulum has increased by 1%, $|dl|/l = 0.01$, so the percentage change in the period of the pendulum is

$$\frac{|\Delta T|}{T} \times 100\% \approx \frac{1}{2}(0.01) \times 100\% = \boxed{0.5\%}.$$

The length of the pendulum has increased, so the period of the pendulum has also increased, meaning that it now takes longer for the pendulum to swing through a full cycle than was designed. Accordingly, the clock loses time each day; specifically, it loses approximately 0.5% of the day, or

$$0.005(24 \text{ hours}) = 0.12 \text{ hours} = \boxed{7.2 \text{ minutes}}$$

each day.

55. If the length of the pendulum is normally 1 meter and the length has been increased by 10 cm, then

$$\frac{|\Delta l|}{l} \times 100\% = \frac{0.1}{1} \times 100\% = 10\%;$$

that is, the length of the pendulum has been increased by 10%. Based on Problem 54, the period of the pendulum will increase by 5%. Accordingly, the clock loses approximately 5% of the day, or

$$0.05(24 \text{ hours}) = 1.2 \text{ hours} = \boxed{72 \text{ minutes}}$$

each day.

56. (a) Let $L(t) = \sigma A[T(t)]^4$. Then

$$\frac{dL}{dt} = 4\sigma AT^3 \frac{dT}{dt},$$

so that

$$\frac{dT}{dt} = \frac{1}{4\sigma T^3} \frac{dL}{dt} = \frac{T}{4\sigma AT^4} \frac{dL}{dt} = \boxed{\frac{T}{4L} \frac{dL}{dt}}.$$

- (b) Let L_c denote the current luminosity and T_c the current temperature of the sun. By part (a),

$$\begin{aligned} \frac{dT}{dt} &= \frac{T_c}{4L_c} \frac{dL}{dt} \approx \frac{T_c}{4L_c} \cdot \frac{\Delta L}{\Delta t} = \frac{T_c}{4L_c} \cdot \frac{0.3L_c}{4.5} \\ &\approx 1.67 \times 10^{-2} T_c \frac{\text{K}}{\text{billion years}} \cdot \frac{1 \text{ billion years}}{10^7 \text{ centuries}} \\ &= \boxed{1.67 \times 10^{-9} T_c \frac{\text{K}}{\text{century}}}. \end{aligned}$$

57. With $\Delta r = dr = 8.8$ km and

$$G = 6.67 \times 10^{-11} \frac{\text{m}^3}{\text{kg} \cdot \text{s}^2} \cdot \left(\frac{1 \text{ km}}{1000 \text{ m}} \right)^3 = 6.67 \times 10^{-20} \frac{\text{km}^3}{\text{kg} \cdot \text{s}^2},$$

it follows that

$$\begin{aligned} \Delta W &\approx dW = -\frac{2GmM}{r^3} dr \\ &= -\frac{2(6.67 \times 10^{-20})(70)(5.974 \times 10^{24})}{(6370)^3} (8.8) \approx -0.0019 \text{ kg}. \end{aligned}$$

Thus, a person who weighs 70 kg at sea level will weigh approximately $\boxed{70 - 0.0019 = 69.9981 \text{ kg}}$ at the top of Mount Everest.

58. (a) The man is 66 inches tall and weighs 142 lb in the morning. Thus, his BMI in the morning is

$$\text{BMI} = 703 \frac{142}{66^2} \approx \boxed{22.917}.$$

With $\Delta m = dm = 148 - 142 = 6$ lb, the change in this man's BMI in the afternoon is approximately

$$\Delta \text{BMI} \approx d\text{BMI} = \frac{703}{h^2} dm = \frac{703}{66^2} (6) \approx \boxed{0.968}.$$

- (b) The actual change in this man's BMI in the afternoon is

$$\Delta \text{BMI} = 703 \frac{148}{66^2} - 703 \frac{142}{66^2} = \frac{703(6)}{66^2} \approx 0.968.$$

Thus, the linear approximation $\boxed{\text{neither underestimates nor overestimates}}$ the change in BMI. The linear approximation provides the exact value for the change because BMI is a linear function of the person's weight.

- (c) A woman who weighs 165 pounds and is 68 inches tall has a BMI of

$$\text{BMI} = 703 \frac{165}{68^2} \approx \boxed{25.085}.$$

If the error in the height measurement is ± 1.5 inches, then $\Delta h = dh = \pm 1.5$ and the possible error in the calculation of BMI is

$$\Delta \text{BMI} \approx d\text{BMI} = -1406 \frac{m}{h^3} dh = -1406 \frac{165}{68^3} (\pm 1.5) \approx \boxed{\pm 1.107}.$$

- (d) Answers will vary. One possible response is that the man's BMI, both in the morning and in the afternoon, would lead to a classification of the man's weight as normal. Using the indicated height of 68 inches, the woman's BMI would lead to a classification as overweight. However, taking into account the possible error in the woman's height, her BMI could be as low as roughly $25.085 - 1.107 = 23.978$, which is in the normal weight range.

59. The volume V of a sphere with radius r is $V = \frac{4}{3}\pi r^3$, so

$$r = \sqrt[3]{\frac{3V}{4\pi}} = \sqrt[3]{\frac{3}{4\pi}} \cdot V^{1/3}.$$

If the volume is measured with an accuracy of $\pm 1\%$, then

$$\frac{|\Delta V|}{V} = \frac{|dV|}{V} \leq 0.01$$

and

$$\frac{|\Delta r|}{r} \approx \frac{|dr|}{r} = \frac{\sqrt[3]{\frac{3}{4\pi}} \cdot \frac{1}{3} V^{-2/3} |dV|}{\sqrt[3]{\frac{3}{4\pi}} \cdot V^{1/3}} = \frac{1}{3} \frac{|dV|}{V} \leq \frac{1}{300}.$$

The percentage error in the radius of the sphere caused by the error in measuring the volume of the sphere is approximately $\boxed{1/3 \%}$.

60. Let $V = \frac{1}{3}\pi h^2(3R - h) = \pi h^2 R - \frac{1}{3}\pi h^3$. Then

$$\Delta V \approx dV = (2\pi h R - \pi h^2) dh = \pi h(2R - h) dh$$

and

$$\frac{\Delta V}{V} \approx \frac{dV}{V} = \frac{\pi h(2R - h) dh}{\frac{1}{3}\pi h^2(3R - h)} = \frac{2R - h}{R - \frac{1}{3}h} \cdot \frac{dh}{h}.$$

If the margin of error in the measurement of h is 10%, then

$$\frac{|\Delta h|}{h} = \frac{|dh|}{h} = 0.1;$$

hence, with $h = 3$ cm and $R = 8$ cm,

$$\frac{|\Delta V|}{V} \approx \frac{|dV|}{V} = \frac{16 - 3}{8 - 1}(0.1) \approx 0.186.$$

The approximate error in the calculated volume is $\boxed{18.6\%}$.

61. The volume V of a cube with edge length s is $V = s^3$. Suppose the percentage error in measuring the edge length is 2%; that is,

$$\frac{|\Delta s|}{s} = \frac{|ds|}{s} = 0.02.$$

Then

$$\frac{|\Delta V|}{V} \approx \frac{|dV|}{V} = \frac{3s^2 |ds|}{s^3} = 3 \frac{|ds|}{s} = 0.06;$$

that is, the percentage error in the calculated volume is approximately $\boxed{6\%}$.

62. Solving the thin-lens equation for q yields

$$\frac{1}{q} = \frac{1}{f} - \frac{1}{p} = \frac{p - f}{pf}, \quad \text{so that} \quad q = \frac{pf}{p - f}.$$

It then follows that

$$\Delta q \approx dq = q'(p) dp = \frac{(p-f)f - pf}{(p-f)^2} dp = -\frac{f^2}{(p-f)^2} dp.$$

With $f = 50 \text{ mm} = 0.05 \text{ m}$, $p = 15 \text{ m}$, and $\Delta p = dp = -0.33 \text{ m}$ (note the dog has moved closer to the lens so that p has decreased),

$$\Delta q \approx dq = -\frac{0.05^2}{(15 - 0.05)^2}(-0.33) \approx 3.69 \times 10^{-6} \text{ m}.$$

Thus, the image of the dog moves approximately $\boxed{3.69 \times 10^{-6} \text{ meters}}$ away from the lens.

63. The figure below displays the graph of $y = e^{-x}$ as the solid curve and the graph of $y = \ln x$ as the dashed curve. The graphs intersect near $x = 1.3$, so let $f(x) = e^{-x} - \ln x$ and take $c_1 = 1.3$. Newton's Method then generates the sequence of approximations:

$$\begin{aligned} c_2 &= c_1 - \frac{f(c_1)}{f'(c_1)} \approx 1.309759929; \\ c_3 &= c_2 - \frac{f(c_2)}{f'(c_2)} \approx 1.309799585; \text{ and} \\ c_4 &= c_3 - \frac{f(c_3)}{f'(c_3)} \approx 1.309799586. \end{aligned}$$

Correct to three decimal places, the solution of the equation $e^{-x} = \ln x$ is $\boxed{x = 1.309}$.

64. The figure below displays the graph of $y = e^{-x}$ as the solid curve and the graph of $y = x - 4$ as the dashed curve. The graphs intersect near $x = 4.0$, so let $f(x) = e^{-x} - x + 4$ and take $c_1 = 4.0$. Newton's Method then generates the sequence of approximations:

$$\begin{aligned} c_2 &= c_1 - \frac{f(c_1)}{f'(c_1)} \approx 4.017986210; \\ c_3 &= c_2 - \frac{f(c_2)}{f'(c_2)} \approx 4.017989103; \text{ and} \\ c_4 &= c_3 - \frac{f(c_3)}{f'(c_3)} \approx 4.017989103. \end{aligned}$$

Correct to three decimal places, the solution of the equation $e^{-x} = x - 4$ is $\boxed{x = 4.017}$.

65. The figure below displays the graph of $y = e^x$ as the solid curve and the graph of $y = x^2$ as the dashed curve. The graphs intersect near $x = -0.7$, so let $f(x) = e^x - x^2$ and take $c_1 = -0.7$. Newton's Method then generates the sequence of approximations:

$$\begin{aligned} c_2 &= c_1 - \frac{f(c_1)}{f'(c_1)} \approx -0.7034721896; \\ c_3 &= c_2 - \frac{f(c_2)}{f'(c_2)} \approx -0.7034674225; \text{ and} \\ c_4 &= c_3 - \frac{f(c_3)}{f'(c_3)} \approx -0.7034674225. \end{aligned}$$

Correct to three decimal places, the solution of the equation $e^x = x^2$ is $\boxed{x = -0.703}$.

66. The equation $e^x = 2 \cos x$ has an infinite number of solutions for $x < 0$. For $x < 0$, the graph of $y = e^x$ asymptotically approaches the x -axis, so there will be a solution “near” each x -intercept of the cosine graph. However, the equation $e^x = 2 \cos x$ has only one solution for $x > 0$. The figure below displays the graph of $y = e^x$ as the solid curve and the graph of $y = 2 \cos x$ as the dashed curve. The graphs intersect near $x = 0.5$, so let $f(x) = e^x - 2 \cos x$ and take $c_1 = 0.5$. Newton's Method then generates the sequence of approximations:

$$\begin{aligned} c_2 &= c_1 - \frac{f(c_1)}{f'(c_1)} \approx 0.5408210546; \\ c_3 &= c_2 - \frac{f(c_2)}{f'(c_2)} \approx 0.5397858311; \text{ and} \\ c_4 &= c_3 - \frac{f(c_3)}{f'(c_3)} \approx 0.5397851608. \end{aligned}$$

Correct to three decimal places, the unique solution of the equation $e^x = 2 \cos x$ for $x > 0$ is $\boxed{x = 0.539}$.

67. Let $f(x) = \ln x - 1$ and take $c_1 = 3.0$. Newton's Method then generates the sequence of approximations:

$$\begin{aligned} c_2 &= c_1 - \frac{f(c_1)}{f'(c_1)} \approx 2.704163134; \\ c_3 &= c_2 - \frac{f(c_2)}{f'(c_2)} \approx 2.718245099; \text{ and} \\ c_4 &= c_3 - \frac{f(c_3)}{f'(c_3)} \approx \boxed{2.718281828}. \end{aligned}$$

A TI-84 Plus calculator gives $e \approx 2.718281828$, so the fourth approximation obtained from Newton's Method matches the calculator to 9 decimal places.

68. Let $f(x) = (1+x)^k$, where x is near 0 and k is any real number. Then $f(0) = 1^k = 1$, $f'(x) = k(1+x)^{k-1}$, $f'(0) = k(1)^{k-1} = k$, and

$$L(x) = f(0) + f'(0)(x-0) = 1 + k(x-0) = 1 + kx.$$

69. Yes, it seems reasonable that if a first-degree polynomial approximates a differentiable function in an interval near x_0 , then a higher-degree polynomial should approximate the function over a wider interval, provided enough derivatives exist near x_0 . The first-degree polynomial is able to match both the value of the original function and the value of the first derivative at x_0 . A higher-degree polynomial then ought to be able to match not only the function value and the value of the first derivative, but also the value of the second derivative, the value of the third derivative, and so on. As more information about the function near x_0 is used, the interval over which the function is approximated should increase.
70. A function needs to be differentiable at x_0 for a linear approximation to be used because the slope of the linear approximation is obtained from the derivative of the original function at x_0 .
71. The Newton's Method formula for calculating approximations is

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}.$$

If $x_{n+1} = x_n$, it means that $f(x_n) = 0$, so $\boxed{x_n \text{ is a zero of the function } f}$.

72. Let $f(x) = -x^3 + 6x^2 - 9x + 6$. Being a polynomial function, f is continuous on the set of all real numbers, so it is continuous on the closed interval $[2, 5]$. Because $f(2) = -8 + 24 - 18 + 6 = 4 > 0$ and $f(5) = -125 + 150 - 45 + 6 = -14 < 0$, the Intermediate Value Theorem guarantees that f has a zero on the interval $(2, 5)$.

Now, $f'(x) = -3x^2 + 12x - 9$, so the n th approximation to the zero obtained by Newton's method is given by

$$c_n = c_{n-1} - \frac{f(c_{n-1})}{f'(c_{n-1})} = c_{n-1} - \frac{-c_{n-1}^3 + 6c_{n-1}^2 - 9c_{n-1} + 6}{-3c_{n-1}^2 + 12c_{n-1} - 9}.$$

Starting with $c_1 = 2.9$, the list below shows the first 18 approximations produced by Newton's method. All calculations were performed using the computer algebra system *Mathematica*.

$c_1 = 2.9$	$c_7 = 0.595639$	$c_{13} = 5.28332$
$c_2 = -7.57544$	$c_8 = 1.47219$	$c_{14} = 4.54902$
$c_3 = -4.43931$	$c_9 = 0.287672$	$c_{15} = 4.25099$
$c_4 = -2.36601$	$c_{10} = 0.957711$	$c_{16} = 4.19749$
$c_5 = -0.998005$	$c_{11} = 8.69768$	$c_{17} = 4.19582$
$c_6 = -0.0819619$	$c_{12} = 6.59733$	$c_{18} = 4.19582$

Thus, Newton's Method does not fail to converge with an initial approximation of $c_1 = 2.9$. With an initial approximation of $c_1 = 3.0$, however, Newton's Method does fail because

$$\boxed{f'(3) = -3(3)^2 + 12(3) - 9 = -27 + 36 - 9 = 0}.$$

73. Let $f(x) = x^3 - 2x + 2$. and $c_1 = 0$. Then $f'(x) = 3x^2 - 2$, and Newton's Method generates the sequence

$$\begin{aligned} c_2 &= c_1 - \frac{f(c_1)}{f'(c_1)} = 0 - \frac{2}{-2} = 1; \\ c_3 &= c_2 - \frac{f(c_2)}{f'(c_2)} = 1 - \frac{1}{1} = 0; \\ c_4 &= c_3 - \frac{f(c_3)}{f'(c_3)} = 0 - \frac{2}{-2} = 1; \\ c_5 &= c_4 - \frac{f(c_4)}{f'(c_4)} = 1 - \frac{1}{1} = 0; \end{aligned}$$

and so on. The approximations oscillate between 1 and 0 and never approach a limit; thus, Newton's Method fails.

74. Let $f(x) = x^8 - 1$. Then $f'(x) = 8x^7$. With $c_1 = 0.1$, Newton's Method produces the second approximation

$$c_2 = c_1 - \frac{f(c_1)}{f'(c_1)} = 0.1 - \frac{(0.1)^8 - 1}{8(0.1)^7} = 1250000.088 \approx 1.250 \times 10^6.$$

Though this is a very poor approximation to the root of 1, using the computer algebra system *Mathematica* to continue calculations, we find that $c_{110} \approx 1.00000$. Thus, Newton's Method has not failed but has required a large number of iterations to converge.

75. Let $f(x) = (x-1)^{1/3}$. Then $f'(x) = \frac{1}{3}(x-1)^{-2/3}$, and the n th approximation to the zero of f obtained by Newton's Method is given by

$$c_n = c_{n-1} - \frac{f(c_{n-1})}{f'(c_{n-1})} = c_{n-1} - \frac{(c_{n-1} - 1)^{1/3}}{\frac{1}{3}(c_{n-1} - 1)^{-2/3}} = c_{n-1} - 3(c_{n-1} - 1) = 3 - 2c_{n-1}.$$

The first ten approximations generated by Newton's Method with an initial approximation of $c_1 = 2$ are

$$\begin{aligned} c_2 &= 3 - 2(2) = -1 & c_3 &= 3 - 2(-1) = 5 \\ c_4 &= 3 - 2(5) = -7 & c_5 &= 3 - 2(-7) = 17 \\ c_6 &= 3 - 2(17) = -31 & c_7 &= 3 - 2(-31) = 65 \\ c_8 &= 3 - 2(65) = -127 & c_9 &= 3 - 2(-127) = 257 \\ c_{10} &= 3 - 2(257) = -511 & c_{11} &= 3 - 2(-511) = 1025. \end{aligned}$$

With further calculations, the even subscripted approximations become unbounded in the negative direction while the odd subscripted approximations become unbounded in the positive direction. Thus, Newton's Method fails to locate the zero of f .

76. (a) Let $f(x) = x^4 + 2x^3 - 2x - 2$. The polynomial function f is continuous on the set of all real numbers, so it is continuous on the closed interval $[-2, -1]$. Because $f(-2) = (-2)^4 + 2(-2)^3 - 2(-2) - 2 = 2 > 0$ and $f(-1) = (-1)^4 + 2(-1)^3 - 2(-1) - 2 = -1 < 0$, the Intermediate Value Theorem guarantees that f has a zero on the interval $(-2, -1)$.

(b) Let $c_1 = -1.5$. Using Newton's Method generates the approximations

$$c_2 = c_1 - \frac{f(c_1)}{f'(c_1)} = -1.84375; \text{ and}$$

$$c_3 = c_2 - \frac{f(c_2)}{f'(c_2)} \approx \boxed{-1.737643}.$$

(c) Because

$$\boxed{f'(-1) = 4(-1)^3 + 6(-1)^2 - 2 = -4 + 6 - 2 = 0},$$

an initial approximation of $c_1 = -1$ cannot be used in Newton's Method.

Challenge Problems

77. Let $S = 0.786$ and $f(x) = 2x^3 - 3x^2 - 0.786$. The figure below displays the graph of f ; the function has a single real zero at approximately $x = 1.6$. Using Newton's Method with a first approximation of $c_1 = 1.6$, yields

$$c_2 = c_1 - \frac{f(c_1)}{f'(c_1)} = 1.6 - \frac{2(1.6)^3 - 3(1.6)^2 - 0.786}{6(1.6)^2 - 6(1.6)} \approx 1.647569444.$$

and

$$c_3 = c_2 - \frac{f(c_2)}{f'(c_2)} \approx 1.645202792.$$

Therefore, the approximate depth of submersion is

$$h = dc_3 \approx 6(1.645202792) = 9.871216754 \approx \boxed{9.871 \text{ inches}}.$$

78. Let $p = 0.2$, $M = 0.85$, and $f(x) = x - 0.2 \sin x - 0.85$. Using Newton's Method with a first approximation of $c_1 = 1$ yields

$$c_2 = c_1 - \frac{f(c_1)}{f'(c_1)} = 1 - \frac{0.15 - 0.2 \sin 1}{1 - 0.2 \cos 1} \approx \boxed{1.020511}.$$

3.5: Taylor Polynomials

Concepts and Vocabulary

1. False. If f is a function with both first and second derivatives defined on an interval containing x_0 , then f can be approximated by the Taylor Polynomial $P_2(x) = f(x_0) + f'(x_0)(x - x_0) + \frac{f''(x_0)}{2!}(x - x_0)^2$.
2. True. A Taylor Polynomial approximation P_n for a function f at x_0 has the following properties: $P_n(x_0) = f(x_0)$ and $P_n^{(k)}(x_0) = f^{(k)}(x_0)$ for derivatives of all order from $k = 1$ to $k = n$.

Skill Building

3. Let $f(x) = 3x^3 + 2x^2 - 6x + 5$ and $x_0 = 1$. Then

$$\begin{array}{ll}
 f(x) = 3x^3 + 2x^2 - 6x + 5, & f(1) = 4, \\
 f'(x) = 9x^2 + 4x - 6, & f'(1) = 7, \\
 f''(x) = 18x + 4, & f''(1) = 22, \\
 f'''(x) = 18, & f'''(1) = 18, \\
 f^{(4)}(x) = 0, & f^{(4)}(1) = 0, \\
 f^{(5)}(x) = 0, & f^{(5)}(1) = 0,
 \end{array}$$

and

$$\begin{aligned}
 P_5(x) &= f(1) + f'(1)(x - 1) + \frac{f''(1)}{2!}(x - 1)^2 + \frac{f'''(1)}{3!}(x - 1)^3 + \frac{f^{(4)}(1)}{4!}(x - 1)^4 + \frac{f^{(5)}(1)}{5!}(x - 1)^5 \\
 &= 4 + 7(x - 1) + \frac{22}{2}(x - 1)^2 + \frac{18}{6}(x - 1)^3 + \frac{0}{24}(x - 1)^4 + \frac{0}{120}(x - 1)^5 \\
 &= \boxed{4 + 7(x - 1) + 11(x - 1)^2 + 3(x - 1)^3}.
 \end{aligned}$$

4. Let $f(x) = 4x^3 - 2x^2 - 4$ and $x_0 = 1$. Then

$$\begin{array}{ll}
 f(x) = 4x^3 - 2x^2 - 4, & f(1) = -2, \\
 f'(x) = 12x^2 - 4x, & f'(1) = 8, \\
 f''(x) = 24x - 4, & f''(1) = 20, \\
 f'''(x) = 24, & f'''(1) = 24, \\
 f^{(4)}(x) = 0, & f^{(4)}(1) = 0, \\
 f^{(5)}(x) = 0, & f^{(5)}(1) = 0,
 \end{array}$$

and

$$\begin{aligned}
 P_5(x) &= f(1) + f'(1)(x - 1) + \frac{f''(1)}{2!}(x - 1)^2 + \frac{f'''(1)}{3!}(x - 1)^3 + \frac{f^{(4)}(1)}{4!}(x - 1)^4 + \frac{f^{(5)}(1)}{5!}(x - 1)^5 \\
 &= -2 + 8(x - 1) + \frac{20}{2}(x - 1)^2 + \frac{24}{6}(x - 1)^3 + \frac{0}{24}(x - 1)^4 + \frac{0}{120}(x - 1)^5 \\
 &= \boxed{-2 + 8(x - 1) + 10(x - 1)^2 + 4(x - 1)^3}.
 \end{aligned}$$

5. Let $f(x) = 2x^4 - 6x^3 + x$ and $x_0 = -1$. Then

$$\begin{aligned}
 f(x) &= 2x^4 - 6x^3 + x, & f(-1) &= 7, \\
 f'(x) &= 8x^3 - 18x^2 + 1, & f'(-1) &= -25, \\
 f''(x) &= 24x^2 - 36x, & f''(-1) &= 60, \\
 f'''(x) &= 48x - 36, & f'''(-1) &= -84, \\
 f^{(4)}(x) &= 48, & f^{(4)}(-1) &= 48, \\
 f^{(5)}(x) &= 0, & f^{(5)}(-1) &= 0,
 \end{aligned}$$

and

$$\begin{aligned}
 P_5(x) &= f(-1) + f'(-1)(x+1) + \frac{f''(-1)}{2!}(x+1)^2 + \frac{f'''(-1)}{3!}(x+1)^3 + \\
 &\quad \frac{f^{(4)}(-1)}{4!}(x+1)^4 + \frac{f^{(5)}(-1)}{5!}(x+1)^5 \\
 &= 7 - 25(x-1) + \frac{60}{2}(x-1)^2 + \frac{-84}{6}(x-1)^3 + \frac{48}{24}(x-1)^4 + \frac{0}{120}(x-1)^5 \\
 &= \boxed{7 - 25(x+1) + 30(x+1)^2 - 14(x+1)^3 + 2(x+1)^4}.
 \end{aligned}$$

6. Let $f(x) = -3x^4 + 2x^2 - 5$ and $x_0 = -1$. Then

$$\begin{aligned}
 f(x) &= -3x^4 + 2x^2 - 5, & f(-1) &= -6, \\
 f'(x) &= -12x^3 + 4x, & f'(-1) &= 8, \\
 f''(x) &= -36x^2 + 4, & f''(-1) &= -32, \\
 f'''(x) &= -72x, & f'''(-1) &= 72, \\
 f^{(4)}(x) &= -72, & f^{(4)}(-1) &= -72, \\
 f^{(5)}(x) &= 0, & f^{(5)}(-1) &= 0,
 \end{aligned}$$

and

$$\begin{aligned}
 P_5(x) &= f(-1) + f'(-1)(x+1) + \frac{f''(-1)}{2!}(x+1)^2 + \frac{f'''(-1)}{3!}(x+1)^3 + \\
 &\quad \frac{f^{(4)}(-1)}{4!}(x+1)^4 + \frac{f^{(5)}(-1)}{5!}(x+1)^5 \\
 &= -6 + 8(x-1) + \frac{-32}{2}(x-1)^2 + \frac{72}{6}(x-1)^3 + \frac{-72}{24}(x-1)^4 + \frac{0}{120}(x-1)^5 \\
 &= \boxed{-6 + 8(x+1) - 16(x+1)^2 + 12(x+1)^3 - 3(x+1)^4}.
 \end{aligned}$$

7. Let $f(x) = x^5$ and $x_0 = 2$. Then

$$\begin{aligned}
 f(x) &= x^5, & f(2) &= 32, \\
 f'(x) &= 5x^4, & f'(2) &= 80, \\
 f''(x) &= 20x^3, & f''(2) &= 160, \\
 f'''(x) &= 60x^2, & f'''(2) &= 240, \\
 f^{(4)}(x) &= 120x, & f^{(4)}(2) &= 240, \\
 f^{(5)}(x) &= 120, & f^{(5)}(2) &= 120,
 \end{aligned}$$

and

$$\begin{aligned}
 P_5(x) &= f(2) + f'(2)(x-2) + \frac{f''(2)}{2!}(x-2)^2 + \frac{f'''(2)}{3!}(x-2)^3 + \frac{f^{(4)}(2)}{4!}(x-2)^4 + \frac{f^{(5)}(2)}{5!}(x-2)^5 \\
 &= 32 + 80(x-2) + \frac{160}{2}(x-2)^2 + \frac{240}{6}(x-2)^3 + \frac{240}{24}(x-2)^4 + \frac{120}{120}(x-2)^5 \\
 &= \boxed{32 + 80(x-2) + 80(x-2)^2 + 40(x-2)^3 + 10(x-2)^4 + (x-2)^5}.
 \end{aligned}$$

8. Let $f(x) = x^6$ and $x_0 = 3$. Then

$$\begin{aligned}
 f(x) &= x^6, & f(3) &= 729, \\
 f'(x) &= 6x^5, & f'(3) &= 1458, \\
 f''(x) &= 30x^4, & f''(3) &= 2430, \\
 f'''(x) &= 120x^3, & f'''(3) &= 3240, \\
 f^{(4)}(x) &= 360x^2, & f^{(4)}(3) &= 3240, \\
 f^{(5)}(x) &= 720x, & f^{(5)}(3) &= 2160,
 \end{aligned}$$

and

$$\begin{aligned}
 P_5(x) &= f(3) + f'(3)(x-3) + \frac{f''(3)}{2!}(x-3)^2 + \frac{f'''(3)}{3!}(x-3)^3 + \frac{f^{(4)}(3)}{4!}(x-3)^4 + \frac{f^{(5)}(3)}{5!}(x-3)^5 \\
 &= 729 + 1458(x-3) + \frac{2430}{2}(x-3)^2 + \frac{3240}{6}(x-3)^3 + \frac{3240}{24}(x-3)^4 + \frac{2160}{120}(x-3)^5 \\
 &= \boxed{729 + 1458(x-3) + 1215(x-3)^2 + 540(x-3)^3 + 135(x-3)^4 + 18(x-3)^5}.
 \end{aligned}$$

9. Let $f(x) = \ln x$ and $x_0 = 1$. Then

$$\begin{aligned}
 f(x) &= \ln x, & f(1) &= 0, \\
 f'(x) &= \frac{1}{x} = x^{-1}, & f'(1) &= 1, \\
 f''(x) &= -x^{-2}, & f''(1) &= -1, \\
 f'''(x) &= 2x^{-3}, & f'''(1) &= 2, \\
 f^{(4)}(x) &= -6x^{-4}, & f^{(4)}(1) &= -6, \\
 f^{(5)}(x) &= 24x^{-5}, & f^{(5)}(1) &= 24,
 \end{aligned}$$

and

$$\begin{aligned}
 P_5(x) &= f(1) + f'(1)(x-1) + \frac{f''(1)}{2!}(x-1)^2 + \frac{f'''(1)}{3!}(x-1)^3 + \frac{f^{(4)}(1)}{4!}(x-1)^4 + \frac{f^{(5)}(1)}{5!}(x-1)^5 \\
 &= 0 + (x-1) + \frac{-1}{2}(x-1)^2 + \frac{2}{6}(x-1)^3 + \frac{-6}{24}(x-1)^4 + \frac{24}{120}(x-1)^5 \\
 &= \boxed{(x-1) - \frac{1}{2}(x-1)^2 + \frac{1}{3}(x-1)^3 - \frac{1}{4}(x-1)^4 + \frac{1}{5}(x-1)^5}.
 \end{aligned}$$

10. Let $f(x) = \ln(1+x)$ and $x_0 = 0$. Then

$$\begin{aligned}
 f(x) &= \ln(1+x), & f(0) &= 0, \\
 f'(x) &= \frac{1}{1+x} = (1+x)^{-1}, & f'(0) &= 1, \\
 f''(x) &= -(1+x)^{-2}, & f''(0) &= -1, \\
 f'''(x) &= 2(1+x)^{-3}, & f'''(0) &= 2, \\
 f^{(4)}(x) &= -6(1+x)^{-4}, & f^{(4)}(0) &= -6, \\
 f^{(5)}(x) &= 24(1+x)^{-5}, & f^{(5)}(0) &= 24,
 \end{aligned}$$

and

$$\begin{aligned}
 P_5(x) &= f(0) + f'(0)(x-0) + \frac{f''(0)}{2!}(x-0)^2 + \frac{f'''(0)}{3!}(x-0)^3 + \frac{f^{(4)}(0)}{4!}(x-0)^4 + \frac{f^{(5)}(0)}{5!}(x-0)^5 \\
 &= 0 + x + \frac{-1}{2}x^2 + \frac{2}{6}x^3 + \frac{-6}{24}x^4 + \frac{24}{120}x^5 = \boxed{x - \frac{1}{2}x^2 + \frac{1}{3}x^3 - \frac{1}{4}x^4 + \frac{1}{5}x^5}.
 \end{aligned}$$

11. Let $f(x) = \frac{1}{x} = x^{-1}$ and $x_0 = 1$. Then

$$\begin{array}{ll}
 f(x) = x^{-1}, & f(1) = 1, \\
 f'(x) = -x^{-2}, & f'(1) = -1, \\
 f''(x) = 2x^{-3}, & f''(1) = 2, \\
 f'''(x) = -6x^{-4}, & f'''(1) = -6, \\
 f^{(4)}(x) = 24x^{-5}, & f^{(4)}(1) = 24, \\
 f^{(5)}(x) = -120x^{-6}, & f^{(5)}(1) = -120,
 \end{array}$$

and

$$\begin{aligned}
 P_5(x) &= f(1) + f'(1)(x-1) + \frac{f''(1)}{2!}(x-1)^2 + \frac{f'''(1)}{3!}(x-1)^3 + \frac{f^{(4)}(1)}{4!}(x-1)^4 + \frac{f^{(5)}(1)}{5!}(x-1)^5 \\
 &= 1 - (x-1) + \frac{2}{2}(x-1)^2 + \frac{-6}{6}(x-1)^3 + \frac{24}{24}(x-1)^4 + \frac{-120}{120}(x-1)^5 \\
 &= \boxed{1 - (x-1) + (x-1)^2 - (x-1)^3 + (x-1)^4 - (x-1)^5}.
 \end{aligned}$$

12. Let $f(x) = \frac{1}{x^2} = x^{-2}$ and $x_0 = 1$. Then

$$\begin{array}{ll}
 f(x) = x^{-2}, & f(1) = 1, \\
 f'(x) = -2x^{-3}, & f'(1) = -2, \\
 f''(x) = 6x^{-4}, & f''(1) = 6, \\
 f'''(x) = -24x^{-5}, & f'''(1) = -24, \\
 f^{(4)}(x) = 120x^{-6}, & f^{(4)}(1) = 120, \\
 f^{(5)}(x) = -720x^{-7}, & f^{(5)}(1) = -720,
 \end{array}$$

and

$$\begin{aligned}
 P_5(x) &= f(1) + f'(1)(x-1) + \frac{f''(1)}{2!}(x-1)^2 + \frac{f'''(1)}{3!}(x-1)^3 + \frac{f^{(4)}(1)}{4!}(x-1)^4 + \frac{f^{(5)}(1)}{5!}(x-1)^5 \\
 &= 1 - 2(x-1) + \frac{6}{2}(x-1)^2 + \frac{-24}{6}(x-1)^3 + \frac{120}{24}(x-1)^4 + \frac{-720}{120}(x-1)^5 \\
 &= \boxed{1 - 2(x-1) + 3(x-1)^2 - 4(x-1)^3 + 5(x-1)^4 - 6(x-1)^5}.
 \end{aligned}$$

13. Let $f(x) = \cos x$ and $x_0 = 0$. Then

$$\begin{array}{ll}
 f(x) = \cos x, & f(0) = 1, \\
 f'(x) = -\sin x, & f'(0) = 0, \\
 f''(x) = -\cos x, & f''(0) = -1, \\
 f'''(x) = \sin x, & f'''(0) = 0, \\
 f^{(4)}(x) = \cos x, & f^{(4)}(0) = 1, \\
 f^{(5)}(x) = -\sin x, & f^{(5)}(0) = 0,
 \end{array}$$

and

$$\begin{aligned}
 P_5(x) &= f(0) + f'(0)(x-0) + \frac{f''(0)}{2!}(x-0)^2 + \frac{f'''(0)}{3!}(x-0)^3 + \frac{f^{(4)}(0)}{4!}(x-0)^4 + \frac{f^{(5)}(0)}{5!}(x-0)^5 \\
 &= 1 + 0 \cdot x + \frac{-1}{2}x^2 + \frac{0}{6}x^3 + \frac{1}{24}x^4 + \frac{0}{120}x^5 = \boxed{1 - \frac{1}{2}x^2 + \frac{1}{24}x^4}.
 \end{aligned}$$

14. Let $f(x) = \sin x$ and $x_0 = \frac{\pi}{4}$. Then

$$\begin{aligned}
 f(x) &= \sin x, & f\left(\frac{\pi}{4}\right) &= \frac{\sqrt{2}}{2}, \\
 f'(x) &= \cos x, & f'\left(\frac{\pi}{4}\right) &= \frac{\sqrt{2}}{2}, \\
 f''(x) &= -\sin x, & f''\left(\frac{\pi}{4}\right) &= -\frac{\sqrt{2}}{2}, \\
 f'''(x) &= -\cos x, & f'''\left(\frac{\pi}{4}\right) &= -\frac{\sqrt{2}}{2}, \\
 f^{(4)}(x) &= \sin x, & f^{(4)}\left(\frac{\pi}{4}\right) &= \frac{\sqrt{2}}{2}, \\
 f^{(5)}(x) &= \cos x, & f^{(5)}\left(\frac{\pi}{4}\right) &= \frac{\sqrt{2}}{2},
 \end{aligned}$$

and

$$\begin{aligned}
 P_5(x) &= f\left(\frac{\pi}{4}\right) + f'\left(\frac{\pi}{4}\right)\left(x - \frac{\pi}{4}\right) + \frac{f''\left(\frac{\pi}{4}\right)}{2!}\left(x - \frac{\pi}{4}\right)^2 + \frac{f'''\left(\frac{\pi}{4}\right)}{3!}\left(x - \frac{\pi}{4}\right)^3 + \\
 &\quad \frac{f^{(4)}\left(\frac{\pi}{4}\right)}{4!}\left(x - \frac{\pi}{4}\right)^4 + \frac{f^{(5)}\left(\frac{\pi}{4}\right)}{5!}\left(x - \frac{\pi}{4}\right)^5 \\
 &= \frac{\sqrt{2}}{2} + \frac{\sqrt{2}}{2}\left(x - \frac{\pi}{4}\right) + \frac{-\sqrt{2}/2}{2}\left(x - \frac{\pi}{4}\right)^2 + \frac{-\sqrt{2}/2}{6}\left(x - \frac{\pi}{4}\right)^3 + \\
 &\quad \frac{\sqrt{2}/2}{24}\left(x - \frac{\pi}{4}\right)^4 + \frac{\sqrt{2}/2}{120}\left(x - \frac{\pi}{4}\right)^5 \\
 &= \boxed{\frac{\sqrt{2}}{2} + \frac{\sqrt{2}}{2}\left(x - \frac{\pi}{4}\right) - \frac{\sqrt{2}}{4}\left(x - \frac{\pi}{4}\right)^2 - \frac{\sqrt{2}}{12}\left(x - \frac{\pi}{4}\right)^3 + \frac{\sqrt{2}}{48}\left(x - \frac{\pi}{4}\right)^4 + \frac{\sqrt{2}}{240}\left(x - \frac{\pi}{4}\right)^5}.
 \end{aligned}$$

15. Let $f(x) = e^{2x}$ and $x_0 = 0$. Then

$$\begin{aligned}
 f(x) &= e^{2x}, & f(0) &= 1, \\
 f'(x) &= 2e^{2x}, & f'(0) &= 2, \\

 \end{aligned}$$

so that

$$f(0) = 0, \quad f'(0) = 1, \quad f''(0) = 0, \quad f'''(0) = 1, \quad f^{(4)}(0) = 0, \quad f^{(5)}(0) = 9,$$

and

$$\begin{aligned}
 P_5(x) &= f(0) + f'(0)(x-0) + \frac{f''(0)}{2!}(x-0)^2 + \frac{f'''(0)}{3!}(x-0)^3 + \frac{f^{(4)}(0)}{4!}(x-0)^4 + \frac{f^{(5)}(0)}{5!}(x-0)^5 \\
 &= 0 + x + \frac{0}{2}x^2 + \frac{1}{6}x^3 + \frac{0}{24}x^4 + \frac{9}{120}x^5 = \boxed{x + \frac{1}{6}x^3 + \frac{3}{40}x^5}.
 \end{aligned}$$

Applications and Extensions

29. Let $f(x) = 3x^2 - 6x + 4$, $x_0 = 1$, and $n = 2$ (because f is a second-degree polynomial). Then

$$\begin{aligned}
 f(x) &= 3x^2 - 6x + 4, & f(1) &= 1, \\
 f'(x) &= 6x - 6, & f'(1) &= 0, \\
 f''(x) &= 6, & f''(1) &= 6,
 \end{aligned}$$

and

$$P_2(x) = f(1) + f'(1)(x-1) + \frac{f''(1)}{2!}(x-1)^2 = 1 + 3(x-1)^2.$$

Therefore, $\boxed{f(x) = 3x^2 - 6x + 4 = 3(x-1)^2 + 1}.$

30. Let $f(x) = 4x^2 - x + 1$, $x_0 = 1$, and $n = 2$ (because f is a second-degree polynomial). Then

$$\begin{aligned}
 f(x) &= 4x^2 - x + 1, & f(1) &= 4, \\
 f'(x) &= 8x - 1, & f'(1) &= 7, \\
 f''(x) &= 8, & f''(1) &= 8,
 \end{aligned}$$

and

$$P_2(x) = f(1) + f'(1)(x-1) + \frac{f''(1)}{2!}(x-1)^2 = 4 + 7(x-1) + 4(x-1)^2.$$

Therefore, $\boxed{f(x) = 4x^2 - x + 1 = 4(x-1)^2 + 7(x-1) + 4}.$

31. Let $f(x) = x^3 + x^2 - 8$, $x_0 = 1$, and $n = 3$ (because f is a third-degree polynomial). Then

$$\begin{aligned} f(x) &= x^3 + x^2 - 8, & f(1) &= -6, \\ f'(x) &= 3x^2 + 2x, & f'(1) &= 5, \\ f''(x) &= 6x + 2, & f''(1) &= 8, \\ f'''(x) &= 6, & f'''(1) &= 6, \end{aligned}$$

and

$$\begin{aligned} P_3(x) &= f(1) + f'(1)(x-1) + \frac{f''(1)}{2!}(x-1)^2 + \frac{f'''(1)}{3!}(x-1)^3 \\ &= -6 + 5(x-1) + 4(x-1)^2 + (x-1)^3. \end{aligned}$$

Therefore, $\boxed{f(x) = x^3 + x^2 - 8 = (x-1)^3 + 4(x-1)^2 + 5(x-1) - 6}.$

32. Let $f(x) = x^4 + 1$, $x_0 = 1$, and $n = 4$ (because f is a fourth-degree polynomial). Then

$$\begin{aligned} f(x) &= x^4 + 1, & f(1) &= 2, \\ f'(x) &= 4x^3, & f'(1) &= 4, \\ f''(x) &= 12x^2, & f''(1) &= 12, \\ f'''(x) &= 24x, & f'''(1) &= 24, \\ f^{(4)}(x) &= 24, & f^{(4)}(1) &= 24, \end{aligned}$$

and

$$\begin{aligned} P_4(x) &= f(1) + f'(1)(x-1) + \frac{f''(1)}{2!}(x-1)^2 + \frac{f'''(1)}{3!}(x-1)^3 + \frac{f^{(4)}(1)}{4!}(x-1)^4 \\ &= 2 + 4(x-1) + 6(x-1)^2 + 4(x-1)^3 + (x-1)^4. \end{aligned}$$

Therefore, $\boxed{f(x) = x^4 + 1 = (x-1)^4 + 4(x-1)^3 + 6(x-1)^2 + 4(x-1) + 2}.$

33. (a) Let $f(x) = \sin^{-1} x$ and $x_0 = \frac{1}{2}$. Then

$$\begin{aligned} f'(x) &= \frac{1}{\sqrt{1-x^2}}, \\ f''(x) &= -\frac{1}{2}(1-x^2)^{-3/2} \cdot (-2x) = \frac{x}{(1-x^2)^{3/2}}, \\ f'''(x) &= \frac{(1-x^2)^{3/2} \cdot 1 - x \cdot \frac{3}{2}(1-x^2)^{1/2}(-2x)}{(1-x^2)^3} = \frac{1-x^2+3x^2}{(1-x^2)^{5/2}} = \frac{1+2x^2}{(1-x^2)^{5/2}}, \text{ and} \\ f^{(4)}(x) &= \frac{(1-x^2)^{5/2}(4x) - (1+2x^2) \cdot \frac{5}{2}(1-x^2)^{3/2}(-2x)}{(1-x^2)^5} \\ &= \frac{4x-4x^3+5x+10x^3}{(1-x^2)^{7/2}} = \frac{6x^3+9x}{(1-x^2)^{7/2}}, \end{aligned}$$

so that

$$f\left(\frac{1}{2}\right) = \frac{\pi}{6}, \quad f'\left(\frac{1}{2}\right) = \frac{2\sqrt{3}}{3}, \quad f''\left(\frac{1}{2}\right) = \frac{4\sqrt{3}}{9}, \quad f'''\left(\frac{1}{2}\right) = \frac{16\sqrt{3}}{9}, \quad f^{(4)}\left(\frac{1}{2}\right) = \frac{224\sqrt{3}}{27},$$

and

$$\begin{aligned}
 P_4(x) &= f\left(\frac{1}{2}\right) + f'\left(\frac{1}{2}\right)\left(x - \frac{1}{2}\right) + \frac{f''\left(\frac{1}{2}\right)}{2!}\left(x - \frac{1}{2}\right)^2 + \\
 &\quad \frac{f'''\left(\frac{1}{2}\right)}{3!}\left(x - \frac{1}{2}\right)^3 + \frac{f^{(4)}\left(\frac{1}{2}\right)}{4!}\left(x - \frac{1}{2}\right)^4 \\
 &= \frac{\pi}{6} + \frac{2\sqrt{3}}{3}\left(x - \frac{1}{2}\right) + \frac{4\sqrt{3}/9}{2}\left(x - \frac{1}{2}\right)^2 + \frac{16\sqrt{3}/9}{6}\left(x - \frac{1}{2}\right)^3 + \frac{224\sqrt{3}/27}{24}x^4 \\
 &= \boxed{\frac{\pi}{6} + \frac{2\sqrt{3}}{3}\left(x - \frac{1}{2}\right) + \frac{2\sqrt{3}}{9}\left(x - \frac{1}{2}\right)^2 + \frac{8\sqrt{3}}{27}\left(x - \frac{1}{2}\right)^3 + \frac{28\sqrt{3}}{81}\left(x - \frac{1}{2}\right)^4}.
 \end{aligned}$$

- (b) The figure below displays the graph of $f(x) = \sin^{-1} x$ as the solid curve and the graph of $P_4(x)$ as the dashed curve.

34. (a) Let $f(x) = \tan^{-1} x$ and $x_0 = 1$. Then

$$\begin{aligned}

$$\begin{aligned} P_3(x) &= f(0) + f'(0)(x-0) + \frac{f''(0)}{2!}(x-0)^2 + \frac{f'''(0)}{3!}(x-0)^3 \\ &= \frac{100}{e^3} + \frac{60}{e^3}x + \frac{24/e^3}{2}x^2 + \frac{2.4/e^3}{6}x^3 = \boxed{\frac{100}{e^3} + \frac{60}{e^3}x + \frac{12}{e^3}x^2 + \frac{2}{5e^3}x^3}. \end{aligned}$$

- (b) The figure below displays the graph of $f(x) = 100e^{-3e^{-0.2x}}$ as the solid curve and the graph of $P_3(x)$ as the dashed curve.

41. (a) Let $f(x) = \sin x$ and $x_0 = 0$. All even-order derivatives of f are equal to $\pm \sin x$, so that when these derivatives are evaluated at $x_0 = 0$, the result is always 0. As even-order derivatives are associated with even powers of x in a Taylor polynomial, it follows that Taylor polynomials for $\sin x$ at $x_0 = 0$ will always contain only terms with odd powers.
- (b) Let $f(x) = \sin x$ and $x_0 = \frac{\pi}{2}$. All even-order derivatives of f are equal to $\pm \sin x$, so that when these derivatives are evaluated at $x_0 = \frac{\pi}{2}$, the result is ± 1 ; on the other hand, all odd-order derivatives of f are equal to $\pm \cos x$, so that when these derivatives are evaluated at $x_0 = \frac{\pi}{2}$, the result is always 0. Thus, when $x_0 = \frac{\pi}{2}$, $P_7(x)$, and in fact all Taylor polynomials for f , will contain only terms with even powers.
42. (a) Let $f(x) = \cos x$ and $x_0 = 0$. All odd-order derivatives of f are equal to $\pm \sin x$, so that when these derivatives are evaluated at $x_0 = 0$, the result is always 0. As odd-order derivatives are associated with odd powers of x in a Taylor polynomial, it follows that Taylor polynomials for $\cos x$ at $x_0 = 0$ will always contain only terms with even powers.

- (b) Let $f(x) = \cos x$ and $x_0 = \frac{\pi}{2}$. All odd-order derivatives of f are equal to $\pm \sin x$, so that when these derivatives are evaluated at $x_0 = \frac{\pi}{2}$, the result is ± 1 ; on the other hand, all even-order derivatives of f are equal to $\pm \cos x$, so that when these derivatives are evaluated at $x_0 = \frac{\pi}{2}$, the result is always 0. Thus, when $x_0 = \frac{\pi}{2}$, $P_6(x)$, and in fact all Taylor polynomials for f , will contain only terms with odd powers.

Challenge Problems

43. Let $f(x) = \sin x - \lambda x$, $x_0 = \pi$, and $n = 2$. Then

$$\begin{aligned} f(x) &= \sin x - \lambda x, & f(\pi) &= -\lambda\pi, \\ f'(x) &= \cos x - \lambda, & f'(\pi) &= -1 - \lambda, \\ f''(x) &= -\sin x, & f''(\pi) &= 0, \end{aligned}$$

and

$$P_2(x) = f(\pi) + f'(\pi)(x - \pi) + \frac{f''(\pi)}{2!}(x - \pi)^2 = \boxed{-\lambda\pi - (1 + \lambda)(x - \pi)}.$$

Setting $P_2(x)$ equal to zero and solving for x yields

$$x = -\frac{\lambda\pi}{1 + \lambda} + \pi = \frac{-\lambda\pi + \pi + \lambda\pi}{1 + \lambda} = \frac{\pi}{1 + \lambda}.$$

44. Let $f(x) = \cot x - \lambda x$, $x_0 = \frac{\pi}{2}$, and $n = 2$. Then

$$\begin{aligned} f(x) &= \cot x - \lambda x, & f\left(\frac{\pi}{2}\right) &= -\frac{\lambda\pi}{2}, \\ f'(x) &= -\csc^2 x - \lambda, & f'\left(\frac{\pi}{2}\right) &= -1 - \lambda, \\ f''(x) &= -2\csc x \cdot (-\csc x \cot x) = 2\csc^2 x \cot x, & f''\left(\frac{\pi}{2}\right) &= 0, \end{aligned}$$

and

$$P_2(x) = f\left(\frac{\pi}{2}\right) + f'\left(\frac{\pi}{2}\right)\left(x - \frac{\pi}{2}\right) + \frac{f''\left(\frac{\pi}{2}\right)}{2!}\left(x - \frac{\pi}{2}\right)^2 = \boxed{-\frac{\lambda\pi}{2} - (1 + \lambda)\left(x - \frac{\pi}{2}\right)}.$$

Setting $P_2(x)$ equal to zero and solving for x yields

$$x = -\frac{\lambda\pi}{2(1 + \lambda)} + \frac{\pi}{2} = \frac{-\lambda\pi + \pi + \lambda\pi}{2(1 + \lambda)} = \frac{\pi}{2(1 + \lambda)}.$$

3.6: Hyperbolic Functions

Concepts and Vocabulary

1. False. $\operatorname{csch} x = \frac{1}{\sinh x}$, and $\frac{1}{\cosh x} = \operatorname{sech} x$.

2. In terms of $\sinh x$ and $\cosh x$, $\tanh x = \frac{\sinh x}{\cosh x}$.

3. False. The domain of $y = \cosh x$ is all real numbers. The range of $y = \cosh x$ is $[1, \infty)$.

4. Because

$$\cosh(-x) = \frac{e^{-x} + e^{-(-x)}}{2} = \frac{e^x + e^{-x}}{2} = \cosh x,$$

$y = \cosh x$ is an (a) even function.

5. False. The correct identity is $\cosh^2 x - \sinh^2 x = 1$.

6. False. $\frac{d}{dx} \sinh x = \cosh x$.

7. True. Because the range of $y = \sinh x$ is all real numbers, the function $\sinh^{-1} x$ is defined for all real numbers.

8. False. $\tanh^{-1} x$ involves the natural logarithm of $\frac{1+x}{1-x}$, whereas $\coth^{-1} x$ involves the natural logarithm of $\frac{1+x}{x-1}$.

Skill Building

9. $\operatorname{csch}(\ln 3) = \frac{2}{e^{\ln 3} - e^{-\ln 3}} = \frac{2}{3 - \frac{1}{3}} = \frac{3}{4}$.

10. $\operatorname{sech}(\ln 2) = \frac{2}{e^{\ln 2} + e^{-\ln 2}} = \frac{2}{2 + \frac{1}{2}} = \frac{4}{5}$.

11. $\cosh^2 x - \sinh^2 x = 1$ for all real numbers x ; therefore,

$$\cosh^2(5) - \sinh^2(5) = 1.$$

12. $\cosh(-\ln 2) = \frac{e^{-\ln 2} + e^{-(-\ln 2)}}{2} = \frac{\frac{1}{2} + 2}{2} = \frac{5}{4}$.

13. $\tanh(0) = \frac{e^0 - e^0}{e^0 + e^0} = \frac{1 - 1}{1 + 1} = 0$.

14. Because $\ln \frac{1}{2} = -\ln 2$, it follows that

$$\sinh\left(\ln \frac{1}{2}\right) = \sinh(-\ln 2) = \frac{e^{-\ln 2} - e^{-(-\ln 2)}}{2} = \frac{\frac{1}{2} - 2}{2} = -\frac{3}{4}.$$

15. Working from the definitions,

$$\begin{aligned}\tanh^2 x + \operatorname{sech}^2 x &= \left(\frac{e^x - e^{-x}}{e^x + e^{-x}} \right)^2 + \left(\frac{2}{e^x + e^{-x}} \right)^2 \\ &= \frac{e^{2x} - 2 + e^{-2x}}{e^{2x} + 2 + e^{-2x}} + \frac{4}{e^{2x} + 2 + e^{-2x}} = \frac{e^{2x} + 2 + e^{-2x}}{e^{2x} + 2 + e^{-2x}} = 1.\end{aligned}$$

Alternately, divide both sides of the identity $\cosh^2 x - \sinh^2 x = 1$ by $\cosh^2 x$ to obtain $1 - \tanh^2 x = \operatorname{sech}^2 x$. Then add $\tanh^2 x$ to both sides to produce the required identity: $\tanh^2 x + \operatorname{sech}^2 x = 1$.

16. Working from the definitions,

$$\begin{aligned}\coth^2 x - \operatorname{csch}^2 x &= \left(\frac{e^x + e^{-x}}{e^x - e^{-x}} \right)^2 - \left(\frac{2}{e^x - e^{-x}} \right)^2 \\ &= \frac{e^{2x} + 2 + e^{-2x}}{e^{2x} - 2 + e^{-2x}} - \frac{4}{e^{2x} - 2 + e^{-2x}} = \frac{e^{2x} - 2 + e^{-2x}}{e^{2x} - 2 + e^{-2x}} = 1.\end{aligned}$$

Alternately, divide both sides of the identity $\cosh^2 x - \sinh^2 x = 1$ by $\sinh^2 x$ to obtain $\coth^2 x - 1 = \operatorname{csch}^2 x$. Then add 1 to and subtract $\operatorname{csch}^2 x$ from both sides to produce the required identity: $\coth^2 x - \operatorname{csch}^2 x = 1$.

$$17. \sinh(-A) = \frac{e^{-A} - e^{-(-A)}}{2} = -\frac{e^A - e^{-A}}{2} = -\sinh(A).$$

$$18. \cosh(-A) = \frac{e^{-A} + e^{-(-A)}}{2} = \frac{e^A + e^{-A}}{2} = \cosh(A).$$

19. Let's start with the expression on the right-hand side and work toward the one on the left-hand side:

$$\begin{aligned}\sinh A \cosh B + \cosh A \sinh B &= \frac{e^A - e^{-A}}{2} \frac{e^B + e^{-B}}{2} + \frac{e^A + e^{-A}}{2} \frac{e^B - e^{-B}}{2} \\ &= \frac{e^{A+B} + e^{A-B} - e^{B-A} - e^{-A-B}}{4} + \frac{e^{A+B} - e^{A-B} + e^{B-A} - e^{-A-B}}{4} \\ &= \frac{2e^{A+B} - 2e^{-A-B}}{4} = \frac{e^{A+B} - e^{-(A+B)}}{2} = \sinh(A+B).\end{aligned}$$

20. Let's start with the expression on the right-hand side and work toward the one on the left-hand side:

$$\begin{aligned}\cosh A \cosh B + \sinh A \sinh B &= \frac{e^A + e^{-A}}{2} \frac{e^B + e^{-B}}{2} + \frac{e^A - e^{-A}}{2} \frac{e^B - e^{-B}}{2} \\ &= \frac{e^{A+B} + e^{A-B} + e^{B-A} + e^{-A-B}}{4} + \frac{e^{A+B} - e^{A-B} - e^{B-A} + e^{-A-B}}{4} \\ &= \frac{2e^{A+B} + 2e^{-A-B}}{4} = \frac{e^{A+B} + e^{-(A+B)}}{2} = \cosh(A+B).\end{aligned}$$

21. Working from the definition,

$$\sinh(2x) = \frac{e^{2x} - e^{-2x}}{2} = \frac{(e^x + e^{-x})(e^x - e^{-x})}{2} = 2 \frac{e^x - e^{-x}}{2} \frac{e^x + e^{-x}}{2} = 2 \sinh x \cosh x.$$

Alternately, by Problem 19 with $A = B = x$,

$$\sinh(2x) = \sinh(x + x) = \sinh x \cosh x + \cosh x \sinh x = 2 \sinh x \cosh x.$$

22. Working from the right-hand side to the left-hand side,

$$\begin{aligned}\cosh^2 x + \sinh^2 x &= \left(\frac{e^x + e^{-x}}{2}\right)^2 + \left(\frac{e^x - e^{-x}}{2}\right)^2 \\ &= \frac{e^{2x} + 2 + e^{-2x}}{4} + \frac{e^{2x} - 2 + e^{-2x}}{4} = \frac{2e^{2x} + 2e^{-2x}}{4} = \frac{e^{2x} + e^{-2x}}{2} = \cosh(2x).\end{aligned}$$

Alternately, by Problem 20 with $A = B = x$,

$$\cosh(2x) = \cosh(x + x) = \cosh x \cosh x + \sinh x \sinh x = \cosh^2 x + \sinh^2 x.$$

23. By Problems 20, 21, and 22,

$$\begin{aligned}\cosh(3x) &= \cosh(2x + x) = \cosh(2x) \cosh x + \sinh(2x) \sinh x \\ &= (\cosh^2 x + \sinh^2 x) \cosh x + (2 \sinh x \cosh x) \sinh x \\ &= \cosh^3 x + 3 \sinh^2 x \cosh x = \cosh^3 x + 3(\cosh^2 x - 1) \cosh x \\ &= 4 \cosh^3 x - 3 \cosh x.\end{aligned}$$

24. By Problems 21 and 22,

$$\tanh(2x) = \frac{\sinh(2x)}{\cosh(2x)} = \frac{2 \sinh x \cosh x}{\cosh^2 x + \sinh^2 x}.$$

Dividing the numerator and denominator of this last expression by $\cosh^2 x$ yields

$$\tanh(2x) = \frac{2 \tanh x}{1 + \tanh^2 x}.$$

25. By the Chain Rule,

$$\frac{d}{dx} \sinh(3x) = \cosh(3x) \frac{d}{dx} (3x) = \boxed{3 \cosh(3x)}.$$

26. By the Chain Rule,

$$\frac{d}{dx} \cosh\left(\frac{x}{2}\right) = \sinh\left(\frac{x}{2}\right) \frac{d}{dx} \left(\frac{x}{2}\right) = \boxed{\frac{1}{2} \sinh\left(\frac{x}{2}\right)}.$$

27. By the Chain Rule,

$$\frac{d}{dx} \cosh(x^2 + 1) = \sinh(x^2 + 1) \frac{d}{dx} (x^2 + 1) = \boxed{2x \sinh(x^2 + 1)}.$$

28. By the Chain Rule,

$$\frac{d}{dx} \cosh(2x^3 - 1) = \sinh(2x^3 - 1) \frac{d}{dx} (2x^3 - 1) = \boxed{6x^2 \sinh(2x^3 - 1)}.$$

29. By the Chain Rule,

$$\frac{d}{dx} \coth\left(\frac{1}{x}\right) = -\operatorname{csch}^2\left(\frac{1}{x}\right) \frac{d}{dx} \left(\frac{1}{x}\right) = \boxed{\frac{1}{x^2} \operatorname{csch}^2\left(\frac{1}{x}\right)}.$$

30. By the Chain Rule,

$$\frac{d}{dx} \tanh(x^2) = \operatorname{sech}^2(x^2) \frac{d}{dx} (x^2) = \boxed{2x \operatorname{sech}^2(x^2)}.$$

31. By the Product Rule and the Chain Rule,

$$\begin{aligned}
 \frac{d}{dx} \sinh x \cosh(4x) &= \sinh x \frac{d}{dx} \cosh(4x) + \cosh(4x) \frac{d}{dx} \sinh x \\
 &= \sinh x \sinh(4x) \frac{d}{dx} (4x) + \cosh(4x) \cosh x \\
 &= \boxed{4 \sinh x \sinh(4x) + \cosh(4x) \cosh x}.
 \end{aligned}$$

32. First note, by Problem 18, $\cosh(-x) = \cosh x$. Then, by the Product Rule and the Chain Rule

$$\begin{aligned}
 \frac{d}{dx} \sinh(2x) \cosh(-x) &= \frac{d}{dx} \sinh(2x) \cosh x = \sinh(2x) \frac{d}{dx} \cosh x + \cosh x \frac{d}{dx} \sinh(2x) \\
 &= \sinh(2x) \sinh x + \cosh x \cosh(2x) \frac{d}{dx} (2x) \\
 &= \boxed{\sinh(2x) \sinh x + 2 \cosh x \cosh(2x)}.
 \end{aligned}$$

33. By the Chain Rule,

$$\frac{d}{dx} \cosh^2 x = 2 \cosh x \frac{d}{dx} \cosh x = \boxed{2 \cosh x \sinh x}.$$

34. By the Chain Rule,

$$\frac{d}{dx} \tanh^2 x = 2 \tanh x \frac{d}{dx} \tanh x = \boxed{2 \tanh x \operatorname{sech}^2 x}.$$

35. By the Product Rule,

$$\frac{d}{dx} e^x \cosh x = e^x \frac{d}{dx} \cosh x + \cosh x \frac{d}{dx} e^x = \boxed{e^x \sinh x + e^x \cosh x}.$$

36. By the Product Rule,

$$\begin{aligned}
 \frac{d}{dx} e^x (\cosh x + \sinh x) &= e^x \frac{d}{dx} (\cosh x + \sinh x) + (\cosh x + \sinh x) \frac{d}{dx} e^x \\
 &= e^x (\sinh x + \cosh x) + e^x (\cosh x + \sinh x) \\
 &= \boxed{2e^x (\cosh x + \sinh x)}.
 \end{aligned}$$

37. By the Product Rule,

$$\frac{d}{dx} (x^2 \operatorname{sech} x) = x^2 \frac{d}{dx} \operatorname{sech} x + \operatorname{sech} x \frac{d}{dx} x^2 = \boxed{-x^2 \operatorname{sech} x \tanh x + 2x \operatorname{sech} x}.$$

38. By the Product Rule,

$$\frac{d}{dx} (x^3 \tanh x) = x^3 \frac{d}{dx} \tanh x + \tanh x \frac{d}{dx} x^3 = \boxed{x^3 \operatorname{sech}^2 x + 3x^2 \tanh x}.$$

39. By the Chain Rule,

$$\frac{d}{dx} \cosh^{-1}(4x) = \frac{1}{\sqrt{(4x)^2 - 1}} \frac{d}{dx} (4x) = \boxed{\frac{4}{\sqrt{16x^2 - 1}}}.$$

40. By the Chain Rule,

$$\frac{d}{dx} \sinh^{-1}(3x) = \frac{1}{\sqrt{(3x)^2 + 1}} \frac{d}{dx} (3x) = \boxed{\frac{3}{\sqrt{9x^2 + 1}}}.$$

41. By the Chain Rule,

$$\frac{d}{dx} \tanh^{-1}(x^2 - 1) = \frac{1}{1 - (x^2 - 1)^2} \frac{d}{dx}(x^2 - 1) = \boxed{\frac{2x}{1 - (x^2 - 1)^2}}.$$

42. By the Chain Rule,

$$\frac{d}{dx} \cosh^{-1}(2x + 1) = \frac{1}{\sqrt{(2x + 1)^2 - 1}} \frac{d}{dx}(2x + 1) = \frac{2}{\sqrt{4x^2 + 4x + 1 - 1}} = \boxed{\frac{1}{\sqrt{x^2 + x}}}.$$

43. By the Product Rule,

$$\frac{d}{dx} x \sinh^{-1} x = x \frac{d}{dx} \sinh^{-1} x + \sinh^{-1} x \frac{d}{dx} x = \boxed{\frac{x}{\sqrt{x^2 + 1}} + \sinh^{-1} x}.$$

44. By the Product Rule,

$$\frac{d}{dx} x^2 \cosh^{-1} x = x^2 \frac{d}{dx} \cosh^{-1} x + \cosh^{-1} x \frac{d}{dx} x^2 = \boxed{\frac{x^2}{\sqrt{x^2 - 1}} + 2x \cosh^{-1} x}.$$

45. By the Chain Rule,

$$\frac{d}{dx} \tanh^{-1}(\tan x) = \frac{1}{1 - \tan^2 x} \frac{d}{dx} \tan x = \boxed{\frac{\sec^2 x}{1 - \tan^2 x}}.$$

46. By the Chain Rule,

$$\frac{d}{dx} \sinh^{-1}(\sin x) = \frac{1}{\sqrt{\sin^2 x + 1}} \frac{d}{dx} \sin x = \boxed{\frac{\cos x}{\sqrt{\sin^2 x + 1}}}.$$

47. Using the Chain Rule twice,

$$\begin{aligned} \frac{d}{dx} \cosh^{-1}(\sqrt{x^2 - 1}) &= \frac{1}{\sqrt{(\sqrt{x^2 - 1})^2 - 1}} \frac{d}{dx} \sqrt{x^2 - 1} \\ &= \frac{1}{\sqrt{x^2 - 1 - 1}} \cdot \frac{1}{2}(x^2 - 1)^{-1/2} \frac{d}{dx}(x^2 - 1) = \boxed{\frac{x}{\sqrt{x^2 - 2\sqrt{x^2 - 1}}}}. \end{aligned}$$

48. Using the Chain Rule twice,

$$\begin{aligned} \frac{d}{dx} \sinh^{-1}(\sqrt{x^2 + 1}) &= \frac{1}{\sqrt{(\sqrt{x^2 + 1})^2 + 1}} \frac{d}{dx} \sqrt{x^2 + 1} \\ &= \frac{1}{\sqrt{x^2 + 1 + 1}} \cdot \frac{1}{2}(x^2 + 1)^{-1/2} \frac{d}{dx}(x^2 + 1) = \boxed{\frac{x}{\sqrt{x^2 + 2\sqrt{x^2 + 1}}}}. \end{aligned}$$

Applications and Extensions

49. Let $g(x) = \cosh x$, $x_0 = 0$, and $n = 6$. Then

$$\begin{aligned}
 g(x) &= \cosh x, & g(0) &= 1, \\
 g'(x) &= \sinh x, & g'(0) &= 0, \\
 g''(x) &= \cosh x, & g''(0) &= 1, \\
 g'''(x) &= \sinh x, & g'''(0) &= 0, \\
 g^{(4)}(x) &= \cosh x, & g^{(4)}(0) &= 1, \\
 g^{(5)}(x) &= \sinh x, & g^{(5)}(0) &= 0, \\
 g^{(6)}(x) &= \cosh x, & g^{(6)}(0) &= 1,
 \end{aligned}$$

and

$$\begin{aligned}
 P_6(x) &= g(0) + g'(0)(x-0) + \frac{g''(0)}{2!}(x-0)^2 + \frac{g'''(0)}{3!}(x-0)^3 + \frac{g^{(4)}(0)}{4!}(x-0)^4 + \\
 &\quad \frac{g^{(5)}(0)}{5!}(x-0)^5 + \frac{g^{(6)}(0)}{6!}(x-0)^6 \\
 &= \boxed{1 + \frac{1}{2}x^2 + \frac{1}{24}x^4 + \frac{1}{720}x^6}.
 \end{aligned}$$

50. Let $f(x) = \tanh x$, $x_0 = 0$, and $n = 7$. Then

$$\begin{aligned}
 f'(x) &= \operatorname{sech}^2 x, \\
 f''(x) &= 2 \operatorname{sech} x (-\operatorname{sech} x \tanh x) = -2 \operatorname{sech}^2 x \tanh x \\
 f'''(x) &= -2 \operatorname{sech}^2 x \operatorname{sech}^2 x + \tanh x [-4 \operatorname{sech} x (-\operatorname{sech} x \tanh x)] = -2 \operatorname{sech}^4 x + 4 \tanh^2 x \operatorname{sech}^2 x \\
 &= -2 \operatorname{sech}^4 x + 4(1 - \operatorname{sech}^2 x) \operatorname{sech}^2 x = 4 \operatorname{sech}^2 x - 6 \operatorname{sech}^4 x, \\
 f^{(4)}(x) &= 8 \operatorname{sech} x (-\operatorname{sech} x \tanh x) - 24 \operatorname{sech}^3 x (-\operatorname{sech} x \tanh x) = 8 \tanh x (3 \operatorname{sech}^4 x - \operatorname{sech}^2 x), \\
 f^{(5)}(x) &= 8 \tanh x (-12 \operatorname{sech}^4 x \tanh x + 2 \operatorname{sech}^2 x \tanh x) + 8 \operatorname{sech}^2 x (3 \operatorname{sech}^4 x - \operatorname{sech}^2 x) \\
 &= 16 \tanh^2 x (\operatorname{sech}^2 x - 6 \operatorname{sech}^4 x) + 24 \operatorname{sech}^6 x - 8 \operatorname{sech}^4 x \\
 &= 16(1 - \operatorname{sech}^2 x)(\operatorname{sech}^2 x - 6 \operatorname{sech}^4 x) + 24 \operatorname{sech}^6 x - 8 \operatorname{sech}^4 x \\
 &= 16 \operatorname{sech}^2 x - 112 \operatorname{sech}^4 x + 96 \operatorname{sech}^6 x + 24 \operatorname{sech}^6 x - 8 \operatorname{sech}^4 x \\
 &= 16 \operatorname{sech}^2 x - 120 \operatorname{sech}^4 x + 120 \operatorname{sech}^6 x, \\
 f^{(6)}(x) &= -32 \operatorname{sech}^2 x \tanh x + 480 \operatorname{sech}^4 x \tanh x - 720 \operatorname{sech}^6 x \tanh x \\
 &= -16 \tanh x (2 \operatorname{sech}^2 x - 30 \operatorname{sech}^4 x + 45 \operatorname{sech}^6 x), \text{ and} \\
 f^{(7)}(x) &= -16 \tanh x (-4 \operatorname{sech}^2 x \tanh x + 120 \operatorname{sech}^4 x \tanh x - 270 \operatorname{sech}^6 x \tanh x) - \\
 &\quad 16 \operatorname{sech}^2 x (2 \operatorname{sech}^2 x - 30 \operatorname{sech}^4 x + 45 \operatorname{sech}^6 x) \\
 &= 32 \tanh^2 x (2 \operatorname{sech}^2 x - 60 \operatorname{sech}^4 x + 135 \operatorname{sech}^6 x) - 32 \operatorname{sech}^4 x + 480 \operatorname{sech}^6 x - 720 \operatorname{sech}^8 x \\
 &= 32(1 - \operatorname{sech}^2 x)(2 \operatorname{sech}^2 x - 60 \operatorname{sech}^4 x + 135 \operatorname{sech}^6 x) - \\
 &\quad 32 \operatorname{sech}^4 x + 480 \operatorname{sech}^6 x - 720 \operatorname{sech}^8 x, \\
 &= 64 \operatorname{sech}^2 x - 1984 \operatorname{sech}^4 x + 6240 \operatorname{sech}^6 x - 4320 \operatorname{sech}^8 x - 32 \operatorname{sech}^4 x + 480 \operatorname{sech}^6 x - 720 \operatorname{sech}^8 x, \\
 &= 64 \operatorname{sech}^2 x - 2016 \operatorname{sech}^4 x + 6720 \operatorname{sech}^6 x - 5040 \operatorname{sech}^8 x,
 \end{aligned}$$

so that

$$f(0) = 0, \quad f'(0) = 1, \quad f''(0) = 0, \quad f'''(0) = -2, \quad f^{(4)}(0) = 0,$$

$$f^{(5)}(0) = 16, \quad f^{(6)}(0) = 0, \quad f^{(7)}(0) = -272,$$

and

$$\begin{aligned}
 P_7(x) &= f(0) + f'(0)(x-0) + \frac{f''(0)}{2!}(x-0)^2 + \frac{f'''(0)}{3!}(x-0)^3 + \frac{f^{(4)}(0)}{4!}(x-0)^4 + \frac{f^{(5)}(0)}{5!}(x-0)^5 + \\
 &\quad \frac{f^{(6)}(0)}{6!}(x-0)^6 + \frac{f^{(7)}(0)}{7!}(x-0)^7 \\
 &= \boxed{x - \frac{1}{3}x^3 + \frac{2}{15}x^5 - \frac{17}{315}x^7}.
 \end{aligned}$$

51. Let $y = 12 \cosh \frac{x}{12} + 20$ model the height of the cable for $-50 \leq x \leq 50$. The slope of the tangent line to the cable is given by

$$y' = \frac{d}{dx} \left(12 \cosh \frac{x}{12} + 20 \right) = 12 \cdot \frac{1}{12} \sinh \frac{x}{12} = \sinh \frac{x}{12}.$$

At $x = 50$, the slope $m_{\tan}$ of the tangent line is

$$m_{\tan} = y'(50) = \sinh \frac{50}{12} = \sinh \frac{25}{6}.$$

Based on the diagram below, we see that

$$\tan \theta = \frac{\Delta x}{\Delta y} \quad \text{and} \quad m_{\tan} = \frac{\Delta y}{\Delta x},$$

where θ is the angle at which the cable meets the support. Thus,

$$\theta = \tan^{-1} \left(\frac{1}{m_{\tan}} \right) = \tan^{-1} \left(\frac{1}{\sinh \frac{25}{6}} \right) \approx \boxed{0.031 \text{ radians}},$$

or approximately $\boxed{1.776^\circ}$.

52. (a) Let $y = 15 \cosh \frac{x}{15} - 10$ model the height of the string of holiday lights assuming that the utility poles are located at $x = \pm 6$. With

$$y' = \frac{d}{dx} \left(15 \cosh \frac{x}{15} - 10 \right) = 15 \cdot \frac{1}{15} \sinh \frac{x}{15} = \sinh \frac{x}{15},$$

the slope of the tangent line at $x = -6$ is

$$y'(-6) = \sinh \left(-\frac{6}{15} \right) = -\sinh \frac{2}{5},$$

and the slope of the tangent line at $x = 6$ is

$$y'(6) = \sinh \left(\frac{6}{15} \right) = \boxed{\sinh \frac{2}{5}},$$

- (b) Because the graph of $y = 15 \cosh \frac{x}{15} - 10$ is symmetric with respect to the y -axis, the angle at which the string of lights meets the pole on the left is the same as the angle at which the string of lights meets the pole on the right. Based on the diagram below, we see that

$$\tan \theta = \frac{\Delta x}{\Delta y} \quad \text{and} \quad m_{\tan} = \frac{\Delta y}{\Delta x},$$

where θ is the angle at which the cable meets the support and $m_{\tan}$ is the slope of the tangent line where the string of lights meets the utility pole. Using the result from part (a), it follows that

$$\theta = \tan^{-1} \left(\frac{1}{m_{\tan}} \right) = \tan^{-1} \left(\frac{1}{\sinh \frac{2}{5}} \right) \approx \boxed{1.181 \text{ radians}},$$

or approximately $\boxed{67.666^\circ}$.

53. Let $y = -68.767 \cosh \left(\frac{0.711x}{68.767} \right) + 693.859$.

- (a) The height of the arch is the value of y when $x = 0$; that is, the height of the arch is

$$\begin{aligned} -68.767 \cosh \left(\frac{0.711(0)}{68.767} \right) + 693.859 &= -68.767 \cosh 0 + 693.859 \\ &= -68.767 \cdot 1 + 693.859 = \boxed{625.092 \text{ feet}}. \end{aligned}$$

- (b) The width of the arch is the distance between the x -intercepts of the graph of y . Solving

$$-68.767 \cosh \left(\frac{0.711x}{68.767} \right) + 693.859 = 0$$

for x yields

$$x = \pm \frac{68.767}{0.711} \cosh^{-1} \frac{693.859}{68.767} \approx \pm 290.372.$$

The width of the arch is therefore approximately $\boxed{580.744 \text{ feet}}$.

- (c) The slope of the arch 50 feet to the left of its center is

$$y'(-50) = -0.711 \sinh \left(\frac{0.711(-50)}{68.767} \right) = -0.711 \sinh \left(-\frac{35.55}{68.767} \right) \approx \boxed{0.384},$$

and the slope of the arch 50 feet to the right of its center is

$$y'(50) = -0.711 \sinh \left(\frac{0.711(50)}{68.767} \right) = -0.711 \sinh \frac{35.55}{68.767} \approx \boxed{-0.384}.$$

- (d) The slope of the arch 200 feet to the left of its center is

$$y'(-200) = -0.711 \sinh \left(\frac{0.711(-200)}{68.767} \right) = -0.711 \sinh \left(-\frac{142.2}{68.767} \right) \approx \boxed{2.766},$$

and the slope of the arch 200 feet to the right of its center is

$$y'(200) = -0.711 \sinh \left(\frac{0.711(200)}{68.767} \right) = -0.711 \sinh \frac{142.2}{68.767} \approx \boxed{-2.766}.$$

- (e) Because the graph of $y = -68.767 \cosh\left(\frac{0.711x}{68.767}\right) + 693.859$ is symmetric with respect to the y -axis, the angle at which the arch meets the ground on the left is the same as the angle at which the arch meets the ground on the right. Moreover, the angle at which the arch meets the ground on the left is

$$\tan^{-1}(m_{\tan}),$$

where $m_{\tan}$ is the slope of the tangent line to the graph of $y = -68.767 \cosh\left(\frac{0.711x}{68.767}\right) + 693.859$ at $x = -290.372$. Now

$$\begin{aligned} m_{\tan} &= y'(-290.372) = -0.711 \sinh\left(\frac{0.711(-290.372)}{68.767}\right) \\ &= -0.711 \sinh\left(-\frac{206.454492}{68.767}\right) = 0.711 \sinh\frac{206.454492}{68.767}, \end{aligned}$$

so the angle at which the arch meets the ground is approximately

$$\tan^{-1}\left(0.711 \sinh\frac{206.454492}{68.767}\right) \approx \boxed{1.432 \text{ radians}},$$

or approximately $\boxed{82.048^\circ}$.

- (f) The figure below displays the graph of the height of the Gateway Arch. Observe that the y -intercept of the graph is slightly larger than 620, and the x -intercepts are roughly $x \pm 290$. These observations support the results found in parts (a) and (b). Moreover, the magnitude of the rate of change of the height of the Gateway Arch is larger at $x = \pm 200$ than it is at $x = \pm 50$, supporting the results found in parts (c) and (d).

54. Let n be any real number. Now

$$\cosh x + \sinh x = \frac{e^x + e^{-x}}{2} + \frac{e^x - e^{-x}}{2} = e^x,$$

so

$$\begin{aligned} (\cosh x + \sinh x)^n &= (e^x)^n = e^{nx} = \frac{2e^{nx}}{2} = \frac{e^{nx} + e^{nx}}{2} \\ &= \frac{e^{nx} + e^{-nx} + e^{nx} - e^{-nx}}{2} = \frac{e^{nx} + e^{-nx}}{2} + \frac{e^{nx} - e^{-nx}}{2} = \cosh(nx) + \sinh(nx). \end{aligned}$$

55. (a)

$$\begin{aligned} \frac{d}{dx} \cosh^{-1} x &= \frac{d}{dx} \ln(x + \sqrt{x^2 - 1}) = \frac{1}{x + \sqrt{x^2 - 1}} \cdot \left(1 + \frac{1}{2}(x^2 - 1)^{-1/2}(2x)\right) \\ &= \frac{1}{x + \sqrt{x^2 - 1}} \cdot \left(1 + \frac{x}{\sqrt{x^2 - 1}}\right) = \frac{1}{x + \sqrt{x^2 - 1}} \cdot \frac{\sqrt{x^2 - 1} + x}{\sqrt{x^2 - 1}} = \frac{1}{\sqrt{x^2 - 1}}. \end{aligned}$$

- (b) The domain of $y = \cosh^{-1} x$ is the set $\{x|x \geq 1\}$, so the domain of y' is at most this same set. However, from part (a), y' is not defined for $x = 1$; therefore, the domain of y' is the set $\boxed{\{x|x > 1\}}$.

56. (a)

$$\begin{aligned}\frac{d}{dx} \tanh^{-1} x &= \frac{d}{dx} \left[\frac{1}{2} \ln \left(\frac{1+x}{1-x} \right) \right] = \frac{1}{2} \frac{d}{dx} (\ln(1+x) - \ln(1-x)) \\ &= \frac{1}{2} \left(\frac{1}{1+x} - \frac{1}{1-x} \cdot (-1) \right) = \frac{1}{2} \left(\frac{1}{1+x} + \frac{1}{1-x} \right) \\ &= \frac{1}{2} \cdot \frac{(1-x) + (1+x)}{1-x^2} = \frac{1}{1-x^2}.\end{aligned}$$

- (b) The domain of $y = \tanh^{-1} x$ is the set $\{x|-1 < x < 1\}$, so the domain of y' is at most this same set. There are no additional restrictions on the domain of y' based on the result from part (a), so the domain of y' is the set $\boxed{\{x|-1 < x < 1\}}$.

57. Using the definition of $\tanh x$ in terms of $\sinh x$ and $\cosh x$ and the Quotient Rule,

$$\begin{aligned}\frac{d}{dx} \tanh x &= \frac{d}{dx} \left(\frac{\sinh x}{\cosh x} \right) = \frac{\cosh x \frac{d}{dx} \sinh x - \sinh x \frac{d}{dx} \cosh x}{\cosh^2 x} \\ &= \frac{\cosh^2 x - \sinh^2 x}{\cosh^2 x} = \frac{1}{\cosh^2 x} = \operatorname{sech}^2 x.\end{aligned}$$

58. Using the definition of $\coth x$ in terms of $\sinh x$ and $\cosh x$ and the Quotient Rule,

$$\begin{aligned}\frac{d}{dx} \coth x &= \frac{d}{dx} \left(\frac{\cosh x}{\sinh x} \right) = \frac{\sinh x \frac{d}{dx} \cosh x - \cosh x \frac{d}{dx} \sinh x}{\sinh^2 x} \\ &= \frac{\sinh^2 x - \cosh^2 x}{\sinh^2 x} = -\frac{1}{\sinh^2 x} = -\operatorname{csch}^2 x.\end{aligned}$$

59. Using the definition of $\operatorname{sech} x$ and the Chain Rule,

$$\begin{aligned}\frac{d}{dx} \operatorname{sech} x &= \frac{d}{dx} (\cosh x)^{-1} = -(\cosh x)^{-2} \frac{d}{dx} \cosh x \\ &= -\frac{1}{\cosh^2 x} \cdot \sinh x = -\frac{1}{\cosh x} \frac{\sinh x}{\cosh x} = -\operatorname{sech} x \tanh x.\end{aligned}$$

60. Using the definition of $\operatorname{csch} x$ and the Chain Rule,

$$\begin{aligned}\frac{d}{dx} \operatorname{csch} x &= \frac{d}{dx} (\sinh x)^{-1} = -(\sinh x)^{-2} \frac{d}{dx} \sinh x \\ &= -\frac{1}{\sinh^2 x} \cdot \cosh x = -\frac{1}{\sinh x} \frac{\cosh x}{\sinh x} = -\operatorname{csch} x \coth x.\end{aligned}$$

61. Let $-1 < x < 1$ and $y = \tanh^{-1} x$. Then

$$\begin{aligned}x &= \tanh y = \frac{e^y - e^{-y}}{e^y + e^{-y}} \\ x(e^y + e^{-y}) &= e^y - e^{-y} \\ e^y(x-1) &= -(1+x)e^{-y} \\ e^{2y} &= -\frac{1+x}{x-1} = \frac{1+x}{1-x}.\end{aligned}$$

With the restriction $-1 < x < 1$, it follows that $0 < 1 + x < 2$ and $0 < 1 - x < 2$. The expression $\frac{1+x}{1-x}$ is therefore defined and positive for $-1 < x < 1$. Taking the natural logarithm of both sides of the last equation and then dividing by 2 yields

$$y = \frac{1}{2} \ln \left(\frac{1+x}{1-x} \right).$$

Thus, $\tanh^{-1} x = \frac{1}{2} \ln \left(\frac{1+x}{1-x} \right)$.

62. Let $x \geq 1$ and $y = \cosh^{-1} x$. Then

$$x = \cosh y = \frac{e^y + e^{-y}}{2} \quad \text{and} \quad e^{2y} - 2xe^y + 1 = 0.$$

By the quadratic formula,

$$e^y = \frac{2x \pm \sqrt{(-2x)^2 - 4}}{2} = x \pm \sqrt{x^2 - 1}.$$

Note that the term $\sqrt{x^2 - 1}$ is defined because of the restriction $x \geq 1$. To determine which sign on the radical is needed, note that $y = \cosh^{-1} x \geq 0$, so $e^y \geq 1$. Pick an x greater than 1, say $x = 3$. Because

$$3 + \sqrt{9 - 1} = 3 + 2\sqrt{2} > 1 \quad \text{and} \quad 3 - \sqrt{9 - 1} = 3 - 2\sqrt{2} \approx 0.172 < 1,$$

it follows that the plus sign is needed. Therefore,

$$e^y = x + \sqrt{x^2 - 1}, \quad \text{so that} \quad y = \cosh^{-1} x = \ln(x + \sqrt{x^2 - 1}).$$

63. Let $|x| > 1$ and $y = \coth^{-1} x$. Then

$$\begin{aligned} x &= \coth y = \frac{e^y + e^{-y}}{e^y - e^{-y}} \\ x(e^y - e^{-y}) &= e^y + e^{-y} \\ e^y(x - 1) &= (1 + x)e^{-y} \\ e^{2y} &= \frac{1 + x}{x - 1}. \end{aligned}$$

When $x > 1$, it follows that $1 + x > 2$ and $x - 1 > 0$; when $x < -1$, it follows that $1 + x < 0$ and $x - 1 < 0$. The expression $\frac{1+x}{x-1}$ is therefore defined and positive for $|x| > 1$. Taking the natural logarithm of both sides of the last equation and then dividing by 2 yields

$$y = \frac{1}{2} \ln \left(\frac{1+x}{x-1} \right).$$

Thus, $\coth^{-1} x = \frac{1}{2} \ln \left(\frac{1+x}{x-1} \right) = \frac{1}{2} \ln \left(\frac{x+1}{x-1} \right)$.

Challenge Problems

64. Recognize that

$$\lim_{x \rightarrow 0} \frac{\sinh x}{x} = \lim_{x \rightarrow 0} \frac{\sinh x - 0}{x - 0} = \lim_{x \rightarrow 0} \frac{\sinh x - \sinh 0}{x - 0} = f'(0),$$

where $f(x) = \sinh x$. Thus,

$$\lim_{x \rightarrow 0} \frac{\sinh x}{x} = \cosh 0 = \boxed{1}.$$

65. Recognize that

$$\lim_{x \rightarrow 0} \frac{\cosh x - 1}{x} = \lim_{x \rightarrow 0} \frac{\cosh x - \cosh 0}{x - 0} = f'(0),$$

where $f(x) = \cosh x$. Thus,

$$\lim_{x \rightarrow 0} \frac{\cosh x - 1}{x} = \sinh 0 = \boxed{0}.$$

66. (a) The figure below displays the graph of $y = f(x) = \frac{1}{2}(e^x + e^{-x}) = \cosh x$.

(b) The slope of the tangent line to the graph of f at the point R is

$$m_{\text{tan}} = f'(r) = \sinh r,$$

so the equation of the tangent line is

$$y - \cosh r = \sinh r(x - r) \quad \text{or} \quad y = x \sinh r + \cosh r - r \sinh r.$$

For $r \neq 0$, $\sinh r \neq 0$, and the x -intercept of this line is $x = r - \coth r$. Therefore, the coordinates of the point Q are $\boxed{(0, r - \coth r)}$.

(c) The length of the line segment $\overline{PQ}$ is

$$|r - (r - \coth r)| = \boxed{|\coth r|}.$$

In the limit as r increases without bound, the length of the segment $\overline{PQ}$ approaches

$$\lim_{r \rightarrow \pm\infty} |\coth r| = \boxed{1}.$$

67. By the Chain Rule,

$$\frac{d}{dx} \sin^{-1}(\cosh x) = \frac{1}{\sqrt{1 - \cosh^2 x}} \cdot \sinh x = \frac{\sinh x}{\sqrt{-\sinh^2 x}},$$

where the identity $\cosh^2 x - \sinh^2 x = 1$ has been used in the last step. Note, however, that the function

$$\frac{\sinh x}{\sqrt{-\sinh^2 x}}$$

is undefined for all real numbers x . The problem here is that the domain of the inverse sine function is the set $\{x | -1 \leq x \leq 1\}$ but the range of the hyperbolic cosine function is the set $\{y | y \geq 1\}$. Thus, the original function $f(x) = \sin^{-1}(\cosh x)$ is defined only for $x = 0$, and so it is not possible to find the derivative of f at any real value of x .

68. Let $f(x) = x \sinh^{-1} x$.

(a) Note that

$$\begin{aligned} \sinh^{-1}(-x) &= \ln(-x + \sqrt{x^2 + 1}) = \ln \left[(-x + \sqrt{x^2 + 1}) \cdot \frac{x + \sqrt{x^2 + 1}}{x + \sqrt{x^2 + 1}} \right] \\ &= \ln \frac{-x^2 + x^2 + 1}{x + \sqrt{x^2 + 1}} = \ln \frac{1}{x + \sqrt{x^2 + 1}} = -\ln(x + \sqrt{x^2 + 1}) = -\sinh^{-1} x. \end{aligned}$$

Therefore,

$$f(-x) = (-x) \sinh^{-1}(-x) = -(-x) \sinh^{-1} x = x \sinh^{-1} x = f(x),$$

and f is an even function.

(b) By the Product Rule,

$$f'(x) = x \cdot \frac{1}{\sqrt{x^2 + 1}} + \sinh^{-1} x = \boxed{\frac{x}{\sqrt{x^2 + 1}} + \sinh^{-1} x},$$

and by the Quotient Rule and the Chain Rule,

$$\begin{aligned} f''(x) &= \frac{\sqrt{x^2 + 1} \cdot 1 - x \cdot \frac{1}{2}(x^2 + 1)^{-1/2}(2x)}{x^2 + 1} + \frac{1}{\sqrt{x^2 + 1}} \\ &= \frac{(x^2 + 1) - x^2}{(x^2 + 1)^{3/2}} + \frac{1}{\sqrt{x^2 + 1}} = \boxed{\frac{x^2 + 2}{(x^2 + 1)^{3/2}}}. \end{aligned}$$

Chapter 3 Review Exercises

$$1. \frac{d}{dx}(ax+b)^n = n(ax+b)^{n-1} \frac{d}{dx}(ax+b) = \boxed{an(ax+b)^{n-1}}.$$

$$2. \frac{d}{dx}\sqrt{2ax} = \sqrt{2a} \frac{d}{dx}x^{1/2} = \sqrt{2a} \cdot \frac{1}{2}x^{-1/2} = \frac{\sqrt{2a}}{2\sqrt{x}} = \boxed{\sqrt{\frac{a}{2x}}}.$$

3.

$$\begin{aligned} \frac{d}{dx}(x\sqrt{1-x}) &= x \frac{d}{dx}(1-x)^{1/2} + \sqrt{1-x} \frac{d}{dx}x \\ &= x \cdot \frac{1}{2}(1-x)^{-1/2} \frac{d}{dx}(1-x) + \sqrt{1-x} = \boxed{-\frac{x}{2(1-x)^{1/2}} + (1-x)^{1/2}}. \end{aligned}$$

$$4. \frac{d}{dx} \left(\frac{1}{\sqrt{x^2+1}} \right) = \frac{d}{dx}(x^2+1)^{-1/2} = -\frac{1}{2}(x^2+1)^{-3/2} \frac{d}{dx}(x^2+1) = \boxed{-\frac{x}{(x^2+1)^{3/2}}}.$$

$$5. \frac{d}{dx}(x^2+4)^{3/2} = \frac{3}{2}(x^2+4)^{1/2} \frac{d}{dx}(x^2+4) = \boxed{3x(x^2+4)^{1/2}}.$$

6.

$$\begin{aligned} \frac{d}{dx} \left(\frac{x^2}{\sqrt{x^2-1}} \right) &= \frac{\sqrt{x^2-1} \frac{d}{dx}x^2 - x^2 \frac{d}{dx}(x^2-1)^{1/2}}{x^2-1} = \frac{\sqrt{x^2-1} \cdot 2x - x^2 \cdot \frac{1}{2}(x^2-1)^{-1/2} \frac{d}{dx}(x^2-1)}{x^2-1} \\ &= \frac{2x\sqrt{x^2-1} - x^3(x^2-1)^{-1/2}}{x^2-1} \cdot \frac{\sqrt{x^2-1}}{\sqrt{x^2-1}} = \frac{2x(x^2-1) - x^3}{(x^2-1)^{3/2}} = \boxed{\frac{x^3-2x}{(x^2-1)^{3/2}}}. \end{aligned}$$

7.

$$\begin{aligned} \frac{d}{dx} \left(\frac{\sqrt{2ax-x^2}}{x} \right) &= \frac{x \frac{d}{dx}(2ax-x^2)^{1/2} - \sqrt{2ax-x^2} \frac{d}{dx}x}{x^2} \\ &= \frac{x \cdot \frac{1}{2}(2ax-x^2)^{-1/2} \frac{d}{dx}(2ax-x^2) - \sqrt{2ax-x^2} \cdot 1}{x^2} \\ &= \frac{x(a-x)(2ax-x^2)^{-1/2} - \sqrt{2ax-x^2}}{x^2} \cdot \frac{\sqrt{2ax-x^2}}{\sqrt{2ax-x^2}} \\ &= \frac{x(a-x) - (2ax-x^2)}{x^2\sqrt{2ax-x^2}} = -\frac{ax}{x^2\sqrt{2ax-x^2}} = \boxed{-\frac{a}{x\sqrt{2ax-x^2}}}. \end{aligned}$$

$$8. \frac{d}{dx}(\sqrt{x} + \sqrt[3]{x}) = \frac{1}{2}x^{-1/2} + \frac{1}{3}x^{-2/3} = \boxed{\frac{1}{2\sqrt{x}} + \frac{1}{3\sqrt[3]{x^2}}}.$$

9. Let $y = (e^x - x)^{5x}$. Then

$$\ln y = \ln[(e^x - x)^{5x}] = 5x \ln(e^x - x),$$

so

$$\begin{aligned} \frac{d}{dx} \ln y &= \frac{d}{dx}[5x \ln(e^x - x)] \\ \frac{1}{y} \frac{dy}{dx} &= 5x \frac{d}{dx} \ln(e^x - x) + \ln(e^x - x) \frac{d}{dx}(5x) \\ &= 5x \cdot \frac{1}{e^x - x} \frac{d}{dx}(e^x - x) + \ln(e^x - x) \cdot 5 \\ &= \frac{5x(e^x - 1)}{e^x - x} + 5 \ln(e^x - x). \end{aligned}$$

Thus,

$$\frac{d}{dx}(e^x - x)^{5x} = \boxed{(e^x - x)^{5x} \left(\frac{5x(e^x - 1)}{e^x - x} + 5 \ln(e^x - x) \right)}.$$

10. Let $\phi(x) = \frac{(x^2 - a^2)^{3/2}}{\sqrt{x + a}}$. Then

$$\ln \phi = \ln \frac{(x^2 - a^2)^{3/2}}{\sqrt{x + a}} = \frac{3}{2} \ln(x^2 - a^2) - \frac{1}{2} \ln(x + a),$$

so

$$\begin{aligned} \frac{d}{dx} \ln \phi &= \frac{d}{dx} \left[\frac{3}{2} \ln(x^2 - a^2) - \frac{1}{2} \ln(x + a) \right] \\ \frac{1}{\phi} \frac{d\phi}{dx} &= \frac{3}{2} \cdot \frac{1}{x^2 - a^2} \frac{d}{dx}(x^2 - a^2) - \frac{1}{2} \cdot \frac{1}{x + a} \frac{d}{dx}(x + a) = \frac{3x}{x^2 - a^2} - \frac{1}{2(x + a)}. \end{aligned}$$

Thus,

$$\frac{d}{dx} \frac{(x^2 - a^2)^{3/2}}{\sqrt{x + a}} = \boxed{\frac{(x^2 - a^2)^{3/2}}{\sqrt{x + a}} \left[\frac{3x}{x^2 - a^2} - \frac{1}{2(x + a)} \right]}.$$

11.

$$\begin{aligned} \frac{d}{dx} \left(\frac{x^2}{(x-1)^2} \right) &= \frac{(x-1)^2 \frac{d}{dx} x^2 - x^2 \frac{d}{dx} (x-1)^2}{(x-1)^4} \\ &= \frac{2x(x-1)^2 - x^2 \cdot 2(x-1) \frac{d}{dx} (x-1)}{(x-1)^4} = \frac{2x(x-1) - 2x^2}{(x-1)^3} = \boxed{-\frac{2x}{(x-1)^3}}. \end{aligned}$$

$$12. \frac{d}{dx} (b^{1/2} - x^{1/2})^2 = 2(b^{1/2} - x^{1/2}) \frac{d}{dx} (b^{1/2} - x^{1/2}) = 2(b^{1/2} - x^{1/2}) \left(-\frac{1}{2} x^{-1/2} \right) = \boxed{-\frac{b^{1/2} - x^{1/2}}{x^{1/2}}}.$$

13.

$$\begin{aligned} \frac{d}{dx} [x \sec(2x)] &= x \frac{d}{dx} \sec(2x) + \sec(2x) \frac{d}{dx} x \\ &= x \sec(2x) \tan(2x) \frac{d}{dx} (2x) + \sec(2x) = \boxed{2x \sec(2x) \tan(2x) + \sec(2x)}. \end{aligned}$$

$$14. \frac{d}{dx} \cos^3 x = 3 \cos^2 x \frac{d}{dx} \cos x = \boxed{-3 \cos^2 x \sin x}.$$

15.

$$\begin{aligned} \frac{d}{dx} \sqrt{a^2 \sin \left(\frac{x}{a} \right)} &= \frac{1}{2} \left[a^2 \sin \left(\frac{x}{a} \right) \right]^{-1/2} \frac{d}{dx} \left[a^2 \sin \left(\frac{x}{a} \right) \right] \\ &= \frac{1}{2} \left[a^2 \sin \left(\frac{x}{a} \right) \right]^{-1/2} \cdot a^2 \cos \left(\frac{x}{a} \right) \frac{d}{dx} \left(\frac{x}{a} \right) = \boxed{\frac{a \cos \left(\frac{x}{a} \right)}{2 \left(a^2 \sin \left(\frac{x}{a} \right) \right)^{1/2}}}. \end{aligned}$$

$$16. \frac{d}{dz} \sqrt{1 + \sin z} = \frac{1}{2} (1 + \sin z)^{-1/2} \frac{d}{dz} (1 + \sin z) = \boxed{\frac{\cos z}{2\sqrt{1 + \sin z}}}.$$

$$17. \frac{d}{dv} \left(\sin v - \frac{1}{3} \sin^3 v \right) = \cos v - \sin^2 v \frac{d}{dv} \sin v = \cos v - \sin^2 v \cos v = \cos v (1 - \sin^2 v) = \boxed{\cos^3 v}.$$

$$18. \frac{d}{dx} \tan \sqrt{\frac{\pi}{x}} = \sec^2 \sqrt{\frac{\pi}{x}} \frac{d}{dx} \sqrt{\pi x^{-1/2}} = \sec^2 \sqrt{\frac{\pi}{x}} \cdot \left(-\frac{1}{2} \sqrt{\pi} x^{-3/2} \right) = \boxed{-\frac{1}{2} \sqrt{\frac{\pi}{x^3}} \sec^2 \sqrt{\frac{\pi}{x}}}.$$

$$19. \frac{d}{dx} (1.05)^x = \boxed{(1.05)^x \ln 1.05}.$$

$$20. \frac{d}{dy} \ln(y^2 + 1) = \frac{1}{y^2 + 1} \frac{d}{dy} (y^2 + 1) = \boxed{\frac{2y}{y^2 + 1}}.$$

21.

$$\begin{aligned} \frac{d}{du} \ln(\sqrt{u^2 + 25} - u) &= \frac{1}{\sqrt{u^2 + 25} - u} \frac{d}{du} [(u^2 + 25)^{1/2} - u] \\ &= \frac{1}{\sqrt{u^2 + 25} - u} \cdot \left(\frac{1}{2} (u^2 + 25)^{-1/2} \frac{d}{du} (u^2 + 25) - 1 \right) \\ &= \frac{1}{\sqrt{u^2 + 25} - u} \cdot \left(\frac{u}{\sqrt{u^2 + 25}} - 1 \right) = \frac{1}{\sqrt{u^2 + 25} - u} \cdot \left(\frac{u - \sqrt{u^2 + 25}}{\sqrt{u^2 + 25}} \right) \\ &= \boxed{-\frac{1}{\sqrt{u^2 + 25}}}. \end{aligned}$$

$$22. \frac{d}{dx} (x^2 + 2^x) = \boxed{2x + 2^x \ln 2}.$$

$$23. \frac{d}{dx} \ln[\sin(2x)] = \frac{1}{\sin(2x)} \frac{d}{dx} \sin(2x) = \frac{\cos(2x)}{\sin(2x)} \frac{d}{dx} (2x) = \boxed{2 \cot(2x)}.$$

24.

$$\begin{aligned} \frac{d}{dx} [e^{-x} \sin(2x + \pi)] &= e^{-x} \frac{d}{dx} \sin(2x + \pi) + \sin(2x + \pi) \frac{d}{dx} e^{-x} \\ &= e^{-x} \cos(2x + \pi) \frac{d}{dx} (2x + \pi) + e^{-x} \sin(2x + \pi) \frac{d}{dx} (-x) \\ &= \boxed{e^{-x} [2 \cos(2x + \pi) - \sin(2x + \pi)]}. \end{aligned}$$

$$25. \frac{d}{dx} \ln(x^2 - 2x) = \frac{1}{x^2 - 2x} \frac{d}{dx} (x^2 - 2x) = \boxed{\frac{2x - 2}{x^2 - 2x}}.$$

26.

$$\begin{aligned} \frac{d}{dx} \ln \frac{x^2 + 1}{x^2 - 1} &= \frac{d}{dx} \ln(x^2 + 1) - \frac{d}{dx} \ln(x^2 - 1) = \frac{1}{x^2 + 1} \frac{d}{dx} (x^2 + 1) - \frac{1}{x^2 - 1} \frac{d}{dx} (x^2 - 1) \\ &= 2x \left(\frac{1}{x^2 + 1} - \frac{1}{x^2 - 1} \right) = 2x \frac{(x^2 - 1) - (x^2 + 1)}{x^4 - 1} = \boxed{-\frac{4x}{x^4 - 1}}. \end{aligned}$$

$$27. \frac{d}{dx} e^{-x} \ln x = e^{-x} \frac{d}{dx} \ln x + \ln x \frac{d}{dx} e^{-x} = \frac{e^{-x}}{x} + e^{-x} \ln x \frac{d}{dx} (-x) = \boxed{e^{-x} \left(\frac{1}{x} - \ln x \right)}.$$

28.

$$\begin{aligned}
\frac{d}{dx} \ln(\sqrt{x+7} - \sqrt{x}) &= \frac{1}{\sqrt{x+7} - \sqrt{x}} \frac{d}{dx} [(x+7)^{1/2} - x^{1/2}] \\
&= \frac{1}{\sqrt{x+7} - \sqrt{x}} \cdot \left(\frac{1}{2} (x+7)^{-1/2} \frac{d}{dx} (x+7) - \frac{1}{2} x^{-1/2} \right) \\
&= \frac{1}{\sqrt{x+7} - \sqrt{x}} \cdot \left(\frac{1}{2\sqrt{x+7}} - \frac{1}{2\sqrt{x}} \right) \\
&= \frac{1}{\sqrt{x+7} - \sqrt{x}} \cdot \frac{\sqrt{x} - \sqrt{x+7}}{2\sqrt{x(x+7)}} = \boxed{-\frac{1}{2\sqrt{x(x+7)}}}.
\end{aligned}$$

29.

$$\begin{aligned}
\frac{d}{dx} \left[\frac{1}{12} \ln \left(\frac{x}{\sqrt{144-x^2}} \right) \right] &= \frac{1}{12} \frac{d}{dx} \ln x - \frac{1}{24} \frac{d}{dx} \ln(144-x^2) = \frac{1}{12x} - \frac{1}{24(144-x^2)} \frac{d}{dx} (144-x^2) \\
&= \frac{1}{12x} + \frac{x}{12(144-x^2)} = \frac{144-x^2+x^2}{12x(144-x^2)} = \boxed{\frac{12}{x(144-x^2)}}.
\end{aligned}$$

$$30. \quad \frac{d}{dx} \ln(\tan^2 x) = 2 \frac{d}{dx} \ln(\tan x) = \frac{2}{\tan x} \frac{d}{dx} \tan x = \boxed{\frac{2 \sec^2 x}{\tan x}}.$$

$$31. \quad \text{Let } f(x) = \frac{e^x(x^2+4)}{x-2}. \text{ Then}$$

$$\ln f(x) = \ln \left(\frac{e^x(x^2+4)}{x-2} \right) = \ln e^x + \ln(x^2+4) - \ln(x-2) = x + \ln(x^2+4) - \ln(x-2),$$

so that

$$\begin{aligned}
\frac{d}{dx} \ln f(x) &= \frac{d}{dx} [x + \ln(x^2+4) - \ln(x-2)] \\
\frac{1}{f(x)} \frac{df}{dx} &= 1 + \frac{1}{x^2+4} \frac{d}{dx} (x^2+4) - \frac{1}{x-2} \frac{d}{dx} (x-2) = 1 + \frac{2x}{x^2+4} - \frac{1}{x-2}.
\end{aligned}$$

Therefore,

$$\frac{d}{dx} \left(\frac{e^x(x^2+4)}{x-2} \right) = \boxed{\frac{e^x(x^2+4)}{x-2} \left(1 + \frac{2x}{x^2+4} - \frac{1}{x-2} \right)}.$$

32.

$$\begin{aligned}
\frac{d}{dx} [\sin^{-1}(x-1) + \sqrt{2x-x^2}] &= \frac{1}{\sqrt{1-(x-1)^2}} \frac{d}{dx} (x-1) + \frac{1}{2} (2x-x^2)^{-1/2} \frac{d}{dx} (2x-x^2) \\
&= \frac{1}{\sqrt{1-x^2+2x-1}} + \frac{1-x}{\sqrt{2x-x^2}} = \boxed{\frac{2-x}{\sqrt{2x-x^2}}}.
\end{aligned}$$

33.

$$\begin{aligned}
\frac{d}{dx} [2\sqrt{x} - 2 \tan^{-1} \sqrt{x}] &= 2 \cdot \frac{1}{2} x^{-1/2} - 2 \cdot \frac{1}{1+(\sqrt{x})^2} \frac{d}{dx} x^{1/2} = \frac{1}{\sqrt{x}} - \frac{2}{1+x} \cdot \frac{1}{2} x^{-1/2} \\
&= \frac{1}{\sqrt{x}} - \frac{1}{(1+x)\sqrt{x}} = \frac{(1+x)-1}{(1+x)\sqrt{x}} = \frac{x}{(1+x)\sqrt{x}} = \boxed{\frac{\sqrt{x}}{1+x}}.
\end{aligned}$$

$$34. \frac{d}{dx} \left(4 \tan^{-1} \frac{x}{2} + x \right) = 4 \cdot \frac{1}{1 + (x/2)^2} \frac{d}{dx} \left(\frac{x}{2} \right) + 1 = \frac{16}{4 + x^2} \cdot \frac{1}{2} + 1 = \frac{8}{4 + x^2} + 1 = \boxed{\frac{12 + x^2}{4 + x^2}}.$$

$$35. \frac{d}{dx} \sin^{-1}(2x - 1) = \frac{1}{\sqrt{1 - (2x - 1)^2}} \frac{d}{dx}(2x - 1) = \frac{2}{\sqrt{1 - 4x^2 + 4x - 1}} = \boxed{\frac{1}{\sqrt{x - x^2}}}.$$

36.

$$\begin{aligned} \frac{d}{dx} \left(x^2 \tan^{-1} \frac{1}{x} \right) &= x^2 \frac{d}{dx} \tan^{-1} \frac{1}{x} + \tan^{-1} \frac{1}{x} \frac{d}{dx} x^2 = x^2 \cdot \frac{1}{1 + (1/x)^2} \frac{d}{dx} \left(\frac{1}{x} \right) + 2x \tan^{-1} \frac{1}{x} \\ &= \frac{x^4}{1 + x^2} \cdot \left(-\frac{1}{x^2} \right) + 2x \tan^{-1} \frac{1}{x} = \boxed{-\frac{x^2}{1 + x^2} + 2x \tan^{-1} \frac{1}{x}}. \end{aligned}$$

37.

$$\begin{aligned} \frac{d}{dx} \left[x \tan^{-1} x - \ln \sqrt{1 + x^2} \right] &= x \frac{d}{dx} \tan^{-1} x + \tan^{-1} x \frac{d}{dx} x - \frac{1}{2} \frac{d}{dx} \ln(1 + x^2) \\ &= \frac{x}{1 + x^2} + \tan^{-1} x - \frac{1}{2(1 + x^2)} \frac{d}{dx} (1 + x^2) \\ &= \frac{x}{1 + x^2} + \tan^{-1} x - \frac{x}{1 + x^2} = \boxed{\tan^{-1} x}. \end{aligned}$$

38.

$$\begin{aligned} \frac{d}{dx} \left[\sqrt{1 - x^2} (\sin^{-1} x) \right] &= \sqrt{1 - x^2} \frac{d}{dx} \sin^{-1} x + \sin^{-1} x \frac{d}{dx} (\sqrt{1 - x^2})^{1/2} \\ &= \sqrt{1 - x^2} \cdot \frac{1}{\sqrt{1 - x^2}} + \sin^{-1} x \cdot \frac{1}{2} (1 - x^2)^{-1/2} \frac{d}{dx} (1 - x^2) \\ &= \boxed{1 - \frac{x \sin^{-1} x}{\sqrt{1 - x^2}}}. \end{aligned}$$

39.

$$\begin{aligned} \frac{d}{dx} \left(\tanh \frac{x}{2} + \frac{2x}{4 + x^2} \right) &= \operatorname{sech}^2 \frac{x}{2} \frac{d}{dx} \left(\frac{x}{2} \right) + \frac{(4 + x^2) \frac{d}{dx} (2x) - 2x \frac{d}{dx} (4 + x^2)}{(4 + x^2)^2} \\ &= \frac{1}{2} \operatorname{sech}^2 \frac{x}{2} + \frac{2(4 + x^2) - 2x(2x)}{(4 + x^2)^2} = \boxed{\frac{1}{2} \operatorname{sech}^2 \frac{x}{2} + \frac{8 - 2x^2}{(4 + x^2)^2}}. \end{aligned}$$

$$40. \frac{d}{dx} (x \sinh x) = x \frac{d}{dx} \sinh x + \sinh x \frac{d}{dx} x = \boxed{x \cosh x + \sinh x}.$$

$$41. \frac{d}{dx} \sqrt{\sinh x} = \frac{1}{2} (\sinh x)^{-1/2} \frac{d}{dx} \sinh x = \boxed{\frac{\cosh x}{2(\sinh x)^{1/2}}}.$$

$$42. \frac{d}{dx} \sinh^{-1} e^x = \frac{1}{\sqrt{1 + (e^x)^2}} \frac{d}{dx} e^x = \boxed{\frac{e^x}{\sqrt{1 + e^{2x}}}}.$$

43. Let $x = y^5 + y$. Then

$$\begin{aligned} \frac{d}{dx} x &= \frac{d}{dx} (y^5 + y) \\ 1 &= 5y^4 \frac{dy}{dx} + \frac{dy}{dx} \\ \frac{dy}{dx} &= \boxed{\frac{1}{5y^4 + 1}}. \end{aligned}$$

44. Let $x = \cos^5 y + \cos y$. Then

$$\begin{aligned}\frac{d}{dx}x &= \frac{d}{dx}(\cos^5 y + \cos y) \\ 1 &= 5\cos^4 y \frac{d}{dx} \cos y - \sin y \frac{dy}{dx} \\ 1 &= -5\cos^4 y \sin y \frac{dy}{dx} - \sin y \frac{dy}{dx} \\ \frac{dy}{dx} &= \boxed{-\frac{1}{\sin y(5\cos^4 y + 1)}}.\end{aligned}$$

45. Let $\ln x + \ln y = x \cos y$. Then

$$\begin{aligned}\frac{d}{dx}(\ln x + \ln y) &= \frac{d}{dx}(x \cos y) \\ \frac{1}{x} + \frac{1}{y} \frac{dy}{dx} &= x \frac{d}{dx} \cos y + \cos y \\ \frac{1}{x} + \frac{1}{y} \frac{dy}{dx} &= -x \sin y \frac{dy}{dx} + \cos y \\ \left(\frac{1}{y} + x \sin y\right) \frac{dy}{dx} &= \cos y - \frac{1}{x} \\ \frac{dy}{dx} &= \frac{\cos y - \frac{1}{x}}{\frac{1}{y} + x \sin y} = \boxed{\frac{y(x \cos y - 1)}{x(1 + xy \sin y)}}.\end{aligned}$$

46. Let $\tan(xy) = x$. Then

$$\begin{aligned}\frac{d}{dx} \tan(xy) &= \frac{d}{dx} x \\ \sec^2(xy) \cdot \left(x \frac{dy}{dx} + y\right) &= 1 \\ x \sec^2(xy) \frac{dy}{dx} &= 1 - y \sec^2(xy) \\ \frac{dy}{dx} &= \boxed{\frac{1 - y \sec^2(xy)}{x \sec^2(xy)}}.\end{aligned}$$

47. Let $y = x + \sin(xy)$. Then

$$\begin{aligned}\frac{dy}{dx} &= \frac{d}{dx}(x + \sin(xy)) \\ \frac{dy}{dx} &= 1 + \cos(xy) \cdot \left(x \frac{dy}{dx} + y\right) \\ (1 - x \cos(xy)) \frac{dy}{dx} &= 1 + y \cos(xy) \\ \frac{dy}{dx} &= \boxed{\frac{1 + y \cos(xy)}{1 - x \cos(xy)}}.\end{aligned}$$

48. Let $x = \ln(\csc y + \cot y)$. Then

$$\begin{aligned}\frac{d}{dx}x &= \frac{d}{dx}\ln(\csc y + \cot y) \\ 1 &= \frac{1}{\csc y + \cot y} \frac{d}{dx}(\csc y + \cot y) \\ 1 &= \frac{1}{\csc y + \cot y} \cdot \left(-\csc y \cot y \frac{dy}{dx} - \csc^2 y \frac{dy}{dx} \right) \\ \frac{dy}{dx} &= -\frac{\csc y + \cot y}{\csc y \cot y + \csc^2 y} = -\frac{\csc y + \cot y}{\csc y(\cot y + \csc y)} = -\frac{1}{\csc y} = \boxed{-\sin y}.\end{aligned}$$

49. Let $xy + 3y^2 = 10x$. Then

$$\begin{aligned}\frac{d}{dx}(xy + 3y^2) &= \frac{d}{dx}(10x) \\ x \frac{dy}{dx} + y + 6y \frac{dy}{dx} &= 10 \\ \frac{dy}{dx} &= \boxed{\frac{10 - y}{x + 6y}},\end{aligned}$$

and

$$\begin{aligned}\frac{d^2y}{dx^2} &= \frac{(x + 6y) \cdot -\frac{dy}{dx} - (10 - y) \cdot \left(1 + 6\frac{dy}{dx}\right)}{(x + 6y)^2} \\ &= \frac{-(10 - y) - (10 - y) - 6(10 - y)\frac{10 - y}{x + 6y}}{(x + 6y)^2} \\ &= \frac{-2(10 - y)(x + 6y) - 6(10 - y)^2}{(x + 6y)^3} \\ &= -\frac{2(10 - y)(x + 6y + 3(10 - y))}{(x + 6y)^3} = \boxed{\frac{2(y - 10)(3y + x + 30)}{(x + 6y)^3}}.\end{aligned}$$

50. Let $y^3 + y = x^2$. Then

$$\begin{aligned}\frac{d}{dx}(y^3 + y) &= \frac{d}{dx}x^2 \\ 3y^2 \frac{dy}{dx} + \frac{dy}{dx} &= 2x \\ \frac{dy}{dx} &= \boxed{\frac{2x}{3y^2 + 1}},\end{aligned}$$

and

$$\begin{aligned}\frac{d^2y}{dx^2} &= \frac{(3y^2 + 1) \cdot 2 - 2x \cdot 6y \frac{dy}{dx}}{(3y^2 + 1)^2} = \frac{2(3y^2 + 1) - \frac{24x^2y}{3y^2 + 1}}{(3y^2 + 1)^2} \\ &= \frac{2(3y^2 + 1)^2 - 24(y^3 + y)y}{(3y^2 + 1)^3} = \frac{18y^4 + 12y^2 + 2 - 24y^4 - 24y^2}{(3y^2 + 1)^3} \\ &= \boxed{\frac{2(1 - 6y^2 - 3y^4)}{(3y^2 + 1)^3}},\end{aligned}$$

where, in going from the end of the first line to the beginning of the second line, we have substituted $y^3 + y$ for x^2 based on the original equation.

51. Let $xe^y = 4x^2$. Then

$$\begin{aligned}\frac{d}{dx}(xe^y) &= \frac{d}{dx}(4x^2) \\ xe^y \frac{dy}{dx} + e^y &= 8x \\ \frac{dy}{dx} &= \boxed{\frac{8x - e^y}{xe^y}},\end{aligned}$$

and

$$\begin{aligned}\frac{d^2y}{dx^2} &= \frac{xe^y \left(8 - e^y \frac{dy}{dx}\right) - (8x - e^y) \left(xe^y \frac{dy}{dx} + e^y\right)}{x^2 e^{2y}} \\ &= \frac{8xe^y - xe^{2y} \frac{dy}{dx} - 8x^2 e^y \frac{dy}{dx} - 8xe^y + xe^{2y} \frac{dy}{dx} + e^{2y}}{x^2 e^{2y}} \\ &= \frac{-8x^2 e^y \frac{dy}{dx} + e^{2y}}{x^2 e^{2y}} = \frac{-8x^2 e^y \left(\frac{8x - e^y}{xe^y}\right) + e^{2y}}{x^2 e^{2y}} \\ &= \boxed{\frac{-64x^2 + 8xe^y + e^{2y}}{x^2 e^{2y}}}.\end{aligned}$$

For $x \neq 0$, the equation $xe^y = 4x^2$ reduces to $e^y = 4x$. Thus, for $x \neq 0$, the derivatives can be simplified to

$$\frac{dy}{dx} = \frac{8x - 4x}{x(4x)} = \frac{1}{x} \quad \text{and} \quad \frac{d^2y}{dx^2} = \frac{-64x^2 + 8x(4x) + (4x)^2}{x^2(4x)^2} = -\frac{1}{x^2}.$$

52. Let $\ln(x+y) = 8x$. Then

$$\begin{aligned}\frac{d}{dx} \ln(x+y) &= \frac{d}{dx}(8x) \\ \frac{1}{x+y} \left(1 + \frac{dy}{dx}\right) &= 8 \\ \frac{dy}{dx} &= \boxed{8(x+y) - 1},\end{aligned}$$

and

$$\frac{d^2y}{dx^2} = 8 + 8 \frac{dy}{dx} = 8 + 8[8(x+y) - 1] = \boxed{64(x+y)}.$$

From the equation $\ln(x+y) = 8x$, it follows that $x+y = e^{8x}$, so the derivatives can be simplified to

$$\frac{dy}{dx} = 8e^{8x} - 1 \quad \text{and} \quad \frac{d^2y}{dx^2} = 64e^{8x}.$$

53. Let $g(x)$ be the inverse function of the function $f(x) = e^{2x}$. Because $f(0) = 1$ and $f'(x) = 2e^{2x}$, it follows that $g(1) = 0$ and

$$g'(1) = \frac{1}{f'(g(1))} = \frac{1}{f'(0)} = \boxed{\frac{1}{2}}.$$

54. Let $g(x)$ be the inverse function of the function $f(x) = \sin x$ restricted to the domain $\left[-\frac{\pi}{2}, \frac{\pi}{2}\right]$. Because

$$f\left(\frac{\pi}{6}\right) = \frac{1}{2} \quad \text{and} \quad f'(x) = \cos x,$$

it follows that $g\left(\frac{1}{2}\right) = \frac{\pi}{6}$ and

$$g'\left(\frac{1}{2}\right) = \frac{1}{f'\left(g\left(\frac{1}{2}\right)\right)} = \frac{1}{f'\left(\frac{\pi}{6}\right)} = \frac{1}{\sqrt{3}/2} = \boxed{\frac{2\sqrt{3}}{3}}.$$

55. First write

$$\lim_{n \rightarrow \infty} \left(1 + \frac{2}{5n}\right)^n = \lim_{n \rightarrow \infty} \left(1 + \frac{1}{5n/2}\right)^{(2/5)(5n/2)} = \left[\lim_{n \rightarrow \infty} \left(1 + \frac{1}{5n/2}\right)^{5n/2} \right]^{2/5}.$$

Now, let $k = 5n/2$. As $n \rightarrow \infty$, $k \rightarrow \infty$ as well, so

$$\lim_{n \rightarrow \infty} \left(1 + \frac{2}{5n}\right)^n = \left[\lim_{n \rightarrow \infty} \left(1 + \frac{1}{5n/2}\right)^{5n/2} \right]^{2/5} = \left[\lim_{k \rightarrow \infty} \left(1 + \frac{1}{k}\right)^k \right]^{2/5} = \boxed{e^{2/5}}.$$

56. Let $k = 3h$. Then $\frac{2}{h} = \frac{6}{k}$ and $k \rightarrow 0$ as $h \rightarrow 0$. Therefore,

$$\lim_{h \rightarrow 0} (1 + 3h)^{2/h} = \lim_{k \rightarrow 0} (1 + k)^{6/k} = \left[\lim_{k \rightarrow 0} (1 + k)^{1/k} \right]^6 = \boxed{e^6}.$$

57. $\sinh 0 = \frac{e^0 - e^0}{2} = \boxed{0}.$

58. $\cosh(\ln 3) = \frac{e^{\ln 3} + e^{-\ln 3}}{2} = \frac{3 + \frac{1}{3}}{2} = \boxed{\frac{5}{3}}.$

59. $\sinh x + \cosh x = \frac{e^x - e^{-x}}{2} + \frac{e^x + e^{-x}}{2} = \frac{2e^x}{2} = e^x.$

60. $\tanh(x + y) = \frac{\sinh(x + y)}{\cosh(x + y)} = \frac{\sinh x \cosh y + \sinh y \cosh x}{\cosh x \cosh y + \sinh x \sinh y} \cdot \frac{\frac{1}{\cosh x \cosh y}}{\frac{1}{\cosh x \cosh y}} = \frac{\tanh x + \tanh y}{1 + \tanh x \tanh y}.$

61. Let $f(x) = \sqrt{1 - \sin^2 x}$, and note that the domain of f is the set of all real numbers because $\sin^2 x \leq 1$ for all real numbers x . Now,

$$f'(x) = \frac{1}{2}(1 - \sin^2 x)^{-1/2} \frac{d}{dx}(1 - \sin^2 x) = \frac{1}{2\sqrt{1 - \sin^2 x}} \cdot -2 \sin x \frac{d}{dx} \sin x = -\frac{\sin x \cos x}{\sqrt{1 - \sin^2 x}}.$$

This function is not defined whenever $\sin^2 x = 1$, or $\sin x = \pm 1$. The domain of f' is therefore the set

$$\boxed{\{x | x \neq \frac{\pi}{2} + n\pi\}, \text{ where } n \text{ is any integer}}.$$

62. Let $f(x) = x^{1/2}(x - 2)^{3/2}$ for all $x \geq 2$. Then

$$f'(x) = x^{1/2} \frac{d}{dx}(x - 2)^{3/2} + (x - 2)^{3/2} \frac{d}{dx} x^{1/2} = \frac{3}{2} x^{1/2} (x - 2)^{1/2} + \frac{1}{2} (x - 2)^{3/2} x^{-1/2}.$$

Thus, the domain of f' is the set $\boxed{\{x | x \geq 2\}}.$

63. Let $f(x) = \sqrt{1 + 6x}$.

(a) $1 + 6x \geq 0$ for $x \geq -\frac{1}{6}$, so the domain of f is the set $\boxed{\left\{x | x \geq -\frac{1}{6}\right\}}$. The range of f is the set

$$\boxed{\{y | y \geq 0\}}.$$

(b) With $f(x) = \sqrt{1 + 6x}$,

$$f'(x) = \frac{1}{2}(1 + 6x)^{-1/2} \frac{d}{dx}(1 + 6x) = \frac{3}{\sqrt{1 + 6x}},$$

so the slope of the line tangent to the graph of f at $x = 4$ is

$$m_{\text{tan}} = f'(4) = \frac{3}{\sqrt{1 + 6(4)}} = \boxed{\frac{3}{5}}.$$

- (c) Using the result of part (b) and the fact that $f(4) = \sqrt{1+6(4)} = 5$, the equation of the line tangent to the graph of f at $x = 4$ is

$$y - 5 = \frac{3}{5}(x - 4) \quad \text{or} \quad y = \frac{3}{5}x + \frac{13}{5}.$$

The y -intercept of this line is $\boxed{y = \frac{13}{5}}$.

- (d) The line $y = x + 12$ has a slope of 1. From part (b),

$$f'(x) = \frac{3}{\sqrt{1+6x}},$$

so the tangent line to the graph of f will have slope 1 when

$$\sqrt{1+6x} = 3 \quad \text{or when} \quad x = \frac{4}{3}.$$

Because $f\left(\frac{4}{3}\right) = \sqrt{1+6\left(\frac{4}{3}\right)} = 3$, the coordinates of the point on the graph of f where the tangent line is parallel to the line $y = x + 12$ are $\boxed{\left(\frac{4}{3}, 3\right)}$.

64. Let $y = x\sqrt{x + (x-1)^2} = x\sqrt{x^2 - x + 1}$. Then

$$\begin{aligned} y' &= x \frac{d}{dx}(x^2 - x + 1)^{1/2} + \sqrt{x^2 - x + 1} \frac{d}{dx}x \\ &= x \cdot \frac{1}{2}(x^2 - x + 1)^{-1/2} \frac{d}{dx}(x^2 - x + 1) + \sqrt{x^2 - x + 1} = \frac{x(2x-1)}{2\sqrt{x^2 - x + 1}} + \sqrt{x^2 - x + 1}. \end{aligned}$$

Thus, the slope of the tangent line to the graph of $y = x\sqrt{x + (x-1)^2}$ at $x = 2$ is

$$m_{\text{tan}} = y'(2) = \frac{2(3)}{2\sqrt{4-2+1}} + \sqrt{4-2+1} = \frac{3}{\sqrt{3}} + \sqrt{3} = 2\sqrt{3},$$

so that the equation of the tangent line is

$$y - 2\sqrt{3} = 2\sqrt{3}(x - 2) \quad \text{or} \quad \boxed{y = 2\sqrt{3}x - 2\sqrt{3}}.$$

Moreover, the slope of the normal line to the graph of $y = x\sqrt{x + (x-1)^2}$ at $x = 2$ is $-\frac{1}{2\sqrt{3}} = -\frac{\sqrt{3}}{6}$, so the equation of the normal line is

$$y - 2\sqrt{3} = -\frac{\sqrt{3}}{6}(x - 2) \quad \text{or} \quad \boxed{y = -\frac{\sqrt{3}}{6}x + \frac{7\sqrt{3}}{3}}.$$

65. Let $x^3 + 2y^2 = x^2y$. Then

$$\begin{aligned} \frac{d}{dx}(x^3 + 2y^2) &= \frac{d}{dx}(x^2y) \\ 3x^2 + 4y \frac{dy}{dx} &= x^2 \frac{dy}{dx} + 2xy \\ (4y - x^2) \frac{dy}{dx} &= 2xy - 3x^2 \\ \frac{dy}{dx} &= \frac{2xy - 3x^2}{4y - x^2}. \end{aligned}$$

Therefore,

$$dy = \boxed{\frac{2xy - 3x^2}{4y - x^2} dx}.$$

66. If there can be up to a 2% error in the measurement of p , then

$$\frac{|\Delta p|}{p} = \frac{|dp|}{p} = 0.02.$$

With $g = (4\pi^2 L)p^{-2}$,

$$\Delta g \approx dg = -2(4\pi^2 L)p^{-3} dp,$$

so

$$\frac{|\Delta g|}{g} \approx \frac{|dg|}{g} = \frac{2(4\pi^2 L)p^{-3} |dp|}{(4\pi^2 L)p^{-2}} = 2 \frac{|dp|}{p} = 0.04.$$

Thus, the approximate percentage error in the computation of g is $\boxed{4\%}$.

67. Let $y = f(x) = x + \ln x$ and $x_0 = 1$. Then $f(1) = 1 + \ln 1 = 1$, $f'(x) = 1 + \frac{1}{x}$, $f'(1) = 2$, and

$$L(x) = f(1) + f'(1)(x - 1) = 1 + 2(x - 1) = \boxed{2x - 1}.$$

68. The volume V of a cube with edge length s is $V = s^3$. Suppose the percentage error in measuring the edge length is 5%; that is,

$$\frac{|\Delta s|}{s} = \frac{|ds|}{s} = 0.05.$$

Then

$$\frac{|\Delta V|}{V} \approx \frac{|dV|}{V} = \frac{3s^2 |ds|}{s^3} = 3 \frac{|ds|}{s} = 0.15;$$

that is, the percentage error in the calculated volume is approximately $\boxed{15\%}$.

69. Let $f(x) = \tan x$.

(a) When $x = 0$,

$$dy = f'(0) dx = \sec^2 0 dx = \boxed{dx}$$

and

$$\Delta y = f(0 + \Delta x) - f(0) = \tan \Delta x - \tan 0 = \boxed{\tan(\Delta x)}.$$

(b) i. With $x = 0$ and $\Delta x = dx = 0.5$,

$$dy = dx = 0.5$$

and

$$\Delta y = \tan 0.5 \approx 0.546302.$$

Thus, $\boxed{|\Delta y - dy| \approx 0.046302}$.

ii. With $x = 0$ and $\Delta x = dx = 0.1$,

$$dy = dx = 0.1$$

and

$$\Delta y = \tan 0.1 \approx 0.100335.$$

Thus, $\boxed{|\Delta y - dy| \approx 0.000335}$.

iii. With $x = 0$ and $\Delta x = dx = 0.01$,

$$dy = dx = 0.01$$

and

$$\Delta y = \tan 0.01 \approx 0.010000333.$$

Thus, $\boxed{|\Delta y - dy| \approx 3.33 \times 10^{-7}}.$

70. Let $f(x) = \ln x$.

(a) When $x = 1$,

$$dy = f'(1) dx = \frac{1}{1} dx = \boxed{dx}$$

and

$$\Delta y = f(1 + \Delta x) - f(1) = \ln(1 + \Delta x) - \ln 1 = \boxed{\ln(1 + \Delta x)}.$$

(b) i. With $x = 1$ and $\Delta x = dx = 0.5$,

$$dy = dx = 0.5$$

and

$$\Delta y = \ln(1 + 0.5) = \ln 1.5 \approx 0.405465.$$

Thus, $\boxed{|\Delta y - dy| \approx 0.094535}.$

ii. With $x = 1$ and $\Delta x = dx = 0.1$,

$$dy = dx = 0.1$$

and

$$\Delta y = \ln(1 + 0.1) = \ln 1.1 \approx 0.095310.$$

Thus, $\boxed{|\Delta y - dy| \approx 0.004690}.$

iii. With $x = 1$ and $\Delta x = dx = 0.01$,

$$dy = dx = 0.01$$

and

$$\Delta y = \ln(1 + 0.01) = \ln 1.01 \approx 0.009950.$$

Thus, $\boxed{|\Delta y - dy| \approx 0.000050}.$

71. Let $f(x) = (x^2 + 1)^{(2-3x)}$. Then

$$\ln f(x) = \ln(x^2 + 1)^{(2-3x)} = (2 - 3x) \ln(x^2 + 1)$$

and

$$\begin{aligned} \frac{d}{dx} \ln f(x) &= \frac{d}{dx} [(2 - 3x) \ln(x^2 + 1)] \\ \frac{1}{f(x)} \frac{df}{dx} &= (2 - 3x) \frac{d}{dx} \ln(x^2 + 1) + \ln(x^2 + 1) \frac{d}{dx} (2 - 3x) \\ &= (2 - 3x) \cdot \frac{1}{x^2 + 1} \frac{d}{dx} (x^2 + 1) - 3 \ln(x^2 + 1) = \frac{2x(2 - 3x)}{x^2 + 1} - 3 \ln(x^2 + 1). \end{aligned}$$

Thus,

$$f'(x) = \frac{df}{dx} = (x^2 + 1)^{(2-3x)} \left(\frac{2x(2 - 3x)}{x^2 + 1} - 3 \ln(x^2 + 1) \right),$$

and

$$f'(1) = 2^{-1} \left(\frac{2(-1)}{2} - 3 \ln 2 \right) = \boxed{-\frac{1}{2}(1 + 3 \ln 2) = -\frac{1}{2}(1 + \ln 8)}.$$

72. Note that

$$\lim_{x \rightarrow 2} \frac{\ln x - \ln 2}{x - 2} = f'(2),$$

where $f(x) = \ln x$. Now,

$$f'(x) = \frac{1}{x},$$

so

$$\lim_{x \rightarrow 2} \frac{\ln x - \ln 2}{x - 2} = f'(2) = \boxed{\frac{1}{2}}.$$

73. Let $x \sin y + y \cos x = 0$. Then

$$\begin{aligned} \frac{d}{dx}(x \sin y + y \cos x) &= \frac{d}{dx} 0 \\ x \frac{d}{dx} \sin y + \sin y + y \frac{d}{dx} \cos x + \cos x \frac{dy}{dx} &= 0 \\ x \cos y \frac{dy}{dx} + \sin y - y \sin x + \cos x \frac{dy}{dx} &= 0 \\ (x \cos y + \cos x) \frac{dy}{dx} &= y \sin x - \sin y \\ y' = \frac{dy}{dx} &= \frac{y \sin x - \sin y}{x \cos y + \cos x}. \end{aligned}$$

Thus, when $x = \frac{\pi}{2}$ and $y = \pi$,

$$y' = \frac{\pi \sin \frac{\pi}{2} - \sin \pi}{\frac{\pi}{2} \cos \pi + \cos \frac{\pi}{2}} = \frac{\pi - 0}{-\frac{\pi}{2} - 0} = \boxed{-2}.$$

74. Let $f(x) = e^{2x}$, $x_0 = 3$, and $n = 4$. Then

$$\begin{aligned} f(x) &= e^{2x}, & f(3) &= e^6, \\ f'(x) &= 2e^{2x}, & f'(3) &= 2e^6, \\ f''(x) &= 4e^{2x}, & f''(3) &= 4e^6, \\ f'''(x) &= 8e^{2x}, & f'''(3) &= 8e^6, \\ f^{(4)}(x) &= 16e^{2x}, & f^{(4)}(3) &= 16e^6, \end{aligned}$$

and

$$\begin{aligned} P_4(x) &= f(3) + f'(3)(x-3) + \frac{f''(3)}{2!}(x-3)^2 + \frac{f'''(3)}{3!}(x-3)^3 + \frac{f^{(4)}(3)}{4!}(x-3)^4 \\ &= \boxed{e^6 + 2e^6(x-3) + 2e^6(x-3)^2 + \frac{4e^6}{3}(x-3)^3 + \frac{2e^6}{3}(x-3)^4}. \end{aligned}$$

75. Let $f(x) = \tan x$, $x_0 = 0$, and $n = 4$. Then

$$\begin{aligned} f'(x) &= \sec^2 x, \\ f''(x) &= 2 \sec x \cdot \sec x \tan x = 2 \sec^2 x \tan x, \\ f'''(x) &= 2 \sec^2 x \cdot \sec^2 x + \tan x \cdot 4 \sec x \cdot \sec x \tan x = 2 \sec^4 x + 4 \sec^2 x \tan^2 x \\ &= 2 \sec^4 x + 4 \sec^2 x (\sec^2 x - 1) = 6 \sec^4 x - 4 \sec^2 x, \text{ and} \\ f^{(4)}(x) &= 24 \sec^3 x \cdot \sec x \tan x - 8 \sec x \cdot \sec x \tan x = 24 \sec^4 x \tan x - 8 \sec^2 x \tan x, \end{aligned}$$

so that

$$f(0) = 0, \quad f'(0) = 1, \quad f''(0) = 0, \quad f'''(0) = 2, \quad f^{(4)}(0) = 0,$$

and

$$\begin{aligned} P_4(x) &= f(0) + f'(0)(x-0) + \frac{f''(0)}{2!}(x-0)^2 + \frac{f'''(0)}{3!}(x-0)^3 + \frac{f^{(4)}(0)}{4!}(x-0)^4 \\ &= \boxed{x + \frac{1}{3}x^3}. \end{aligned}$$

76. Let $f(x) = \frac{1}{1+x} = (1+x)^{-1}$, $x_0 = 1$, and $n = 4$. Then

$$\begin{aligned} f(x) &= (1+x)^{-1}, & f(1) &= \frac{1}{2}, \\ f'(x) &= -(1+x)^{-2}, & f'(1) &= -\frac{1}{4}, \\ f''(x) &= 2(1+x)^{-3}, & f''(1) &= \frac{1}{4}, \\ f'''(x) &= -6(1+x)^{-4}, & f'''(1) &= -\frac{3}{8}, \\ f^{(4)}(x) &= 24(1+x)^{-5}, & f^{(4)}(1) &= \frac{3}{4}, \end{aligned}$$

and

$$\begin{aligned} P_4(x) &= f(1) + f'(1)(x-1) + \frac{f''(1)}{2!}(x-1)^2 + \frac{f'''(1)}{3!}(x-1)^3 + \frac{f^{(4)}(1)}{4!}(x-1)^4 \\ &= \boxed{\frac{1}{2} - \frac{1}{4}(x-1) + \frac{1}{8}(x-1)^2 - \frac{1}{16}(x-1)^3 + \frac{1}{32}(x-1)^4}. \end{aligned}$$

77. Let $f(x) = \ln x$, $x_0 = 2$, and $n = 6$. Then

$$\begin{aligned} f(x) &= \ln x, & f(2) &= \ln 2, \\ f'(x) &= \frac{1}{x} = x^{-1}, & f'(2) &= \frac{1}{2}, \\ f''(x) &= -x^{-2}, & f''(2) &= -\frac{1}{4}, \\ f'''(x) &= 2x^{-3}, & f'''(2) &= \frac{1}{4}, \\ f^{(4)}(x) &= -6x^{-4}, & f^{(4)}(2) &= -\frac{3}{8}, \\ f^{(5)}(x) &= 24x^{-5}, & f^{(5)}(2) &= \frac{3}{4}, \\ f^{(6)}(x) &= -120x^{-6}, & f^{(6)}(2) &= -\frac{15}{8}, \end{aligned}$$

and

$$\begin{aligned} P_6(x) &= f(2) + f'(2)(x-2) + \frac{f''(2)}{2!}(x-2)^2 + \frac{f'''(2)}{3!}(x-2)^3 + \frac{f^{(4)}(2)}{4!}(x-2)^4 + \\ &\quad \frac{f^{(5)}(2)}{5!}(x-2)^5 + \frac{f^{(6)}(2)}{6!}(x-2)^6 \\ &= \boxed{\ln 2 + \frac{1}{2}(x-2) - \frac{1}{8}(x-2)^2 + \frac{1}{24}(x-2)^3 - \frac{1}{64}(x-2)^4 + \frac{1}{160}(x-2)^5 - \frac{1}{384}(x-2)^6}. \end{aligned}$$

78. (a) Let $f(x) = 8x^4 - 2x^2 + 5x - 1$. The polynomial function f is continuous on the set of all real numbers, so it is continuous on the closed interval $[0, 1]$. Because $f(0) = -1 < 0$ and $f(1) = 8 - 2 + 5 - 1 = 10 > 0$, the Intermediate Value Theorem guarantees that f has a zero on the interval $(0, 1)$.

(b) With $f(x) = 8x^4 - 2x^2 + 5x - 1$, $f'(x) = 32x^3 - 4x + 5$. Let $c_1 = 0.5$ be the first approximation for Newton's Method. Then

$$c_2 = c_1 - \frac{f(c_1)}{f'(c_1)} = 0.5 - \frac{1.5}{7} \approx 0.285714.$$

Next, $f(c_2) \approx 0.318616$ and $f'(c_2) \approx 4.603497$, so

$$c_3 = c_2 - \frac{f(c_2)}{f'(c_2)} \approx 0.285714 - \frac{0.318616}{4.603497} \approx \boxed{0.216502}.$$

79. (a) Let $f(x) = 2 - x + \sin x$. The function f is continuous on the set of all real numbers, so it is continuous on the closed interval $\left[\frac{\pi}{2}, \pi\right]$. Because $f\left(\frac{\pi}{2}\right) = 2 - \frac{\pi}{2} + 1 \approx 1.429 > 0$ and $f(\pi) = 2 - \pi + 0 \approx -1.142 < 0$, the Intermediate Value Theorem guarantees that f has a zero on the interval $\left(\frac{\pi}{2}, \pi\right)$.

- (b) With $f(x) = 2 - x + \sin x$, $f'(x) = -1 + \cos x$. Let $c_1 = \frac{\pi}{2}$ be the first approximation for Newton's Method. Then

$$c_2 = c_1 - \frac{f(c_1)}{f'(c_1)} = \frac{\pi}{2} - \frac{3 - \frac{\pi}{2}}{-1} = 3.$$

Next, $f(c_2) \approx -0.858880$ and $f'(c_2) \approx -1.989992$, so

$$c_3 = c_2 - \frac{f(c_2)}{f'(c_2)} \approx 3 - \frac{-0.858880}{-1.989992} \approx \boxed{2.568400}.$$

80. (a) Let $f(x) = 2 \cos x - e^x$. The function f is continuous on the set of all real numbers, so it is continuous on the closed interval $[0, 1]$. Because $f(0) = 2 - 1 = 1 > 0$ and $f(1) = 2 \cos 1 - e \approx -1.638 < 0$, the Intermediate Value Theorem guarantees that f has a zero on the interval $(0, 1)$.

- (b) Begin by calculating $f'(x) = -2 \sin x - e^x$. Then, using a TI-84 Plus graphing calculator with $c_1 = 0.5$ yields

$$\begin{aligned} c_2 &= c_1 - \frac{f(c_1)}{f'(c_1)} \approx 0.5408210546; \\ c_3 &= c_2 - \frac{f(c_2)}{f'(c_2)} \approx 0.5397858311; \\ c_4 &= c_3 - \frac{f(c_3)}{f'(c_3)} \approx 0.5397851608; \text{ and} \\ c_5 &= c_4 - \frac{f(c_4)}{f'(c_4)} \approx \boxed{0.5397851608}. \end{aligned}$$

81. Let $4xy - y^2 = 3$. Then

$$\begin{aligned} \frac{d}{dx}(4xy - y^2) &= \frac{d}{dx}3 \\ 4x \frac{dy}{dx} + 4y - 2y \frac{dy}{dx} &= 0 \\ \frac{dy}{dx} &= -\frac{2y}{2x - y}. \end{aligned}$$

The slope of the tangent line to the graph of $4xy - y^2 = 3$ at the point $(1, 3)$ is

$$m_{\text{tan}} = -\frac{2(3)}{2 - 3} = 6,$$

so the equation of the tangent line is

$$y - 3 = 6(x - 1) \quad \text{or} \quad \boxed{y = 6x - 3}.$$

Chapter 4: Applications of the Derivative

4.1: Related Rates

Concepts and Vocabulary

1. If a spherical balloon of volume V is inflated at a rate of $10 \text{ m}^3/\text{min}$, where t is the time (in minutes), then the rate of change of V with respect to t is

$$\frac{dV}{dt} = \boxed{10 \text{ m}^3/\text{min}}.$$

2. For the balloon in Problem 1, if the radius r is increasing at the rate of $0.5 \text{ m}/\text{min}$, then the rate of change of r with respect to t is

$$\frac{dr}{dt} = \boxed{0.5 \text{ m}/\text{min}}.$$

3. Let $x^2 + y^2 = 25$. Then, differentiating with respect to t yields

$$2x \frac{dx}{dt} + 2y \frac{dy}{dt} = 0 \quad \text{or} \quad \frac{dx}{dt} = -\frac{y}{x} \frac{dy}{dt}.$$

Given that $x = 3$, $y = 4$ and $\frac{dy}{dt} = 2$, it follows that

$$\frac{dx}{dt} = -\frac{4}{3} \cdot 2 = \boxed{-\frac{8}{3}}.$$

4. Let $x^3 y^2 = 432$. Then, differentiating with respect to t yields

$$2x^3 y \frac{dy}{dt} + 3x^2 y^2 \frac{dx}{dt} = 0 \quad \text{or} \quad \frac{dx}{dt} = -\frac{2x}{3y} \frac{dy}{dt}.$$

Given that $x = 3$, $y = 4$ and $\frac{dy}{dt} = 2$, it follows that

$$\frac{dx}{dt} = -\frac{2(3)}{3(4)} \cdot 2 = \boxed{-1}.$$

Skill Building

5. Let $V = \frac{1}{12}\pi h^3$. Then, differentiating with respect to t yields

$$\frac{dV}{dt} = \frac{1}{4}\pi h^2 \frac{dh}{dt}.$$

Given that $\frac{dh}{dt} = \frac{5\pi}{16}$ when $h = 8$, it follows that when $h = 8$,

$$\frac{dV}{dt} = \frac{1}{4}\pi(8)^2 \cdot \frac{5\pi}{16} = \boxed{5\pi^2}.$$

6. Let $s^2 = x^2 + y^2$. Then, differentiating with respect to t yields

$$2s \frac{ds}{dt} = 2x \frac{dx}{dt} + 2y \frac{dy}{dt} \quad \text{or} \quad \frac{ds}{dt} = \frac{1}{s} \left(x \frac{dx}{dt} + y \frac{dy}{dt} \right).$$

Given that $\frac{dx}{dt} = 5$, $\frac{dy}{dt} = 4$, $x = 150$, and $y = 80$ when $t = 20$, it follows that when $t = 20$

$$s^2 = 150^2 + 80^2 = 28,900 \quad \text{so that} \quad s = \pm\sqrt{28900} = \pm 170,$$

and

$$\frac{ds}{dt} = \pm \frac{1}{170} (150 \cdot 5 + 80 \cdot 4) = \boxed{\pm \frac{1070}{170} \approx \pm 6.294}.$$

7. Let $V = 80h^2$. Then, differentiating with respect to t yields

$$\frac{dV}{dt} = 160h \frac{dh}{dt}.$$

Given that $\frac{dh}{dt} = \frac{1}{12}$ when $h = 3$, it follows that when $h = 3$,

$$\frac{dV}{dt} = 160(3) \cdot \frac{1}{12} = \boxed{40}.$$

8. Let $y^2 = 625 - x^2$. Then, differentiating with respect to t yields

$$2y \frac{dy}{dt} = -2x \frac{dx}{dt} \quad \text{or} \quad \frac{dy}{dt} = -\frac{x}{y} \frac{dx}{dt}.$$

Given that $\frac{dx}{dt} = 3$ when $x = 15$ and that $y \geq 0$, it follows that when $x = 15$

$$y^2 = 625 - 15^2 = 400 \quad \text{so that} \quad y = 20,$$

and

$$\frac{dy}{dt} = \frac{15}{20} \cdot 3 = \boxed{\frac{9}{4}}.$$

9. The volume V of a cube with edge length x is $V = x^3$. Differentiating with respect to time t yields

$$\frac{dV}{dt} = 3x^2 \frac{dx}{dt}.$$

Given that $\frac{dx}{dt} = 3$ cm/s, it follows that when $x = 10$ cm,

$$\frac{dV}{dt} = 3(10)^2 \cdot 3 = 900.$$

When the length of a side of the cube is 10 cm, the volume is increasing at a rate of $\boxed{900 \text{ cm}^3/\text{s}}$.

10. The volume V of a sphere of radius r is $V = \frac{4}{3}\pi r^3$. Differentiating with respect to time t yields

$$\frac{dV}{dt} = 4\pi r^2 \frac{dr}{dt}.$$

Given that $\frac{dr}{dt} = 1$ cm/s, it follows that when $r = 6$ cm,

$$\frac{dV}{dt} = 4\pi(6)^2 \cdot 1 = 144\pi.$$

When the radius of the sphere is 6 cm, the volume is increasing at a rate of $\boxed{144\pi \text{ cm}^3/\text{s} \approx 452.389 \text{ cm}^3/\text{s}}$.

11. The surface area S of a sphere of radius r is $S = 4\pi r^2$. Differentiating with respect to time t yields

$$\frac{dS}{dt} = 8\pi r \frac{dr}{dt} \quad \text{so that} \quad \frac{dr}{dt} = \frac{1}{8\pi r} \frac{dS}{dt}.$$

Given that $\frac{dS}{dt} = -0.1 \text{ cm}^2/\text{h}$, it follows that when $r = \frac{20}{\pi} \text{ cm}$,

$$\frac{dr}{dt} = \frac{1}{8\pi(20/\pi)} \cdot -0.1 = -\frac{1}{1600} = -0.000625.$$

When the radius of the sphere is $\frac{20}{\pi} \text{ cm}$, the radius is decreasing at a rate of $\boxed{0.000625 \text{ cm/h}}$.

12. The surface area S of a sphere of radius r is $S = 4\pi r^2$. Differentiating with respect to time t yields

$$\frac{dS}{dt} = 8\pi r \frac{dr}{dt}.$$

Given that $\frac{dr}{dt} = 2 \text{ cm/min}$, it follows that when $r = 100 \text{ cm}$

$$\frac{dS}{dt} = 8\pi(100) \cdot 2 = 1600\pi.$$

When the radius of the sphere is 100 cm , the surface area is increasing at a rate of $\boxed{1600\pi \text{ cm}^2/\text{min} \approx 5026.548 \text{ cm}^2/\text{min}}$.

13. Let x and y denote the lengths of the legs of a right triangle with hypotenuse of length 45 cm . By the Pythagorean theorem, $x^2 + y^2 = 45^2$. Differentiating with respect to time t yields

$$2x \frac{dx}{dt} + 2y \frac{dy}{dt} = 0 \quad \text{or} \quad \frac{dy}{dt} = -\frac{x}{y} \frac{dx}{dt}.$$

Given that $\frac{dx}{dt} = 2 \text{ cm/min}$, it follows that when $x = 4 \text{ cm}$,

$$y = \sqrt{45^2 - 4^2} = \sqrt{2009} \text{ cm},$$

and

$$\frac{dy}{dt} = -\frac{4}{\sqrt{2009}} \cdot 2 = -\frac{8}{\sqrt{2009}}.$$

When $x = 4 \text{ cm}$, y is decreasing at a rate of $\boxed{\frac{8}{\sqrt{2009}} \text{ cm/min} \approx 0.178 \text{ cm/min}}$.

14. Let x and θ be defined as indicated in the figure below. These quantities are related by the formula $x = \sin \theta$, and the area A of the triangle is given by

$$A = \frac{1}{2}(1)^2 \sin(2\theta) = \frac{1}{2} \sin(2\theta).$$

Differentiating both formulas with respect to time t yields

$$\frac{dx}{dt} = \cos \theta \frac{d\theta}{dt} \quad \text{and} \quad \frac{dA}{dt} = \cos(2\theta) \frac{d\theta}{dt}.$$

Solving the former equation for $\frac{d\theta}{dt}$ and substituting into the latter equation leads to

$$\frac{dA}{dt} = \cos(2\theta) \cdot \frac{1}{\cos \theta} \frac{dx}{dt} = \frac{\cos(2\theta)}{\cos \theta} \frac{dx}{dt}.$$

Given that $\frac{dx}{dt} = 1$ cm/min, it follows that when $\theta = 30^\circ$,

$$\frac{dA}{dt} = \frac{\cos 60^\circ}{\cos 30^\circ}(1) = \frac{1}{\sqrt{3}} = \frac{\sqrt{3}}{3}.$$

When $\theta = 30^\circ$, the area of the triangle is increasing at a rate of $\boxed{\frac{\sqrt{3}}{3} \text{ cm}^2/\text{min} \approx 0.577 \text{ cm}^2/\text{min}}.$

15. The area of an isosceles triangle with equal sides of length 4 cm and an included angle θ is $A = \frac{1}{2}4^2 \sin \theta = 8 \sin \theta$. Differentiating with respect to time t yields

$$\frac{dA}{dt} = 8 \cos \theta \frac{d\theta}{dt}.$$

Given that $\frac{d\theta}{dt} = 2^\circ/\text{min} = \frac{\pi}{90}$ radians/min, it follows that when $\theta = 30^\circ$

$$\frac{dA}{dt} = 8 \cos 30^\circ \frac{\pi}{90} = \frac{2\sqrt{3}\pi}{45}.$$

When $\theta = 30^\circ$, the area of the triangle is increasing at a rate of $\boxed{\frac{2\sqrt{3}\pi}{45} \text{ cm}^2/\text{min} \approx 0.242 \text{ cm}^2/\text{min}}.$

16. Let s_1 and s_2 denote the lengths of the sides of the rectangle and suppose that s_1 is increasing at the rate of $2\sqrt{5}$ cm/s. Then

$$s_2 = \sqrt{15^2 - s_1^2} = \sqrt{225 - s_1^2},$$

and the area A of the rectangle is

$$A = s_1 s_2 = s_1 \sqrt{225 - s_1^2}.$$

Differentiating with respect to time t yields

$$\frac{dA}{dt} = s_1 \cdot \frac{1}{2}(225 - s_1^2)^{-1/2}(-2s_1) \frac{ds_1}{dt} + \sqrt{225 - s_1^2} \frac{ds_1}{dt} = \left(\sqrt{225 - s_1^2} - \frac{s_1^2}{\sqrt{225 - s_1^2}} \right) \frac{ds_1}{dt}.$$

Given that $\frac{ds_1}{dt} = 2\sqrt{5}$ cm/s, it follows that when $s_1 = 10$ cm,

$$\frac{dA}{dt} = \left(\sqrt{225 - 100} - \frac{100}{\sqrt{225 - 100}} \right) 2\sqrt{5} = \left(5\sqrt{5} - \frac{20}{\sqrt{5}} \right) 2\sqrt{5} = 50 - 40 = 10.$$

When $s_1 = 10$ cm, the area of the rectangle is increasing at a rate of $\boxed{10 \text{ cm}^2/\text{s}}.$

17. The volume V and surface area S of a sphere of radius r are $V = \frac{4}{3}\pi r^3$ and $S = 4\pi r^2$. Differentiating both formulas with respect to time t yields

$$\frac{dV}{dt} = 4\pi r^2 \frac{dr}{dt} \quad \text{and} \quad \frac{dS}{dt} = 8\pi r \frac{dr}{dt}.$$

Solving the former equation for $\frac{dr}{dt}$ and substituting that expression into the latter formula gives

$$\frac{dr}{dt} = \frac{1}{4\pi r^2} \frac{dV}{dt} \quad \text{so that} \quad \frac{dS}{dt} = \frac{8\pi r}{4\pi r^2} \frac{dV}{dt} = \frac{2}{r} \frac{dV}{dt}.$$

Given that $\frac{dV}{dt} = -1.5 \text{ m}^3/\text{min}$, it follows that when $r = 4 \text{ m}$,

$$\frac{dS}{dt} = \frac{2}{4}(-1.5) = -0.75.$$

When the radius of the balloon is 4 m, the surface area is shrinking at a rate of $\boxed{0.75 \text{ m}^2/\text{min}}$.

18. The volume V and surface area S of a sphere of radius r are $V = \frac{4}{3}\pi r^3$ and $S = 4\pi r^2$. Differentiating the volume formula with respect to time t yields

$$\frac{dV}{dt} = 4\pi r^2 \frac{dr}{dt}.$$

Given that the volume of ice decreases at a rate proportional to the surface area, it also follows that

$$\frac{dV}{dt} = kS = k(4\pi r^2),$$

where $k < 0$ is a constant of proportionality. Equating the two expressions for dV/dt yields

$$4\pi r^2 \frac{dr}{dt} = k(4\pi r^2) \quad \text{or} \quad \frac{dr}{dt} = k.$$

Therefore, the radius of the sphere decreases at a constant rate.

Applications and Extensions

19. Let x denote the distance from the lower end of the ladder to the wall against which the ladder is leaning. Then

$$\cos \theta = \frac{x}{5} \quad \text{and} \quad -\sin \theta \frac{d\theta}{dt} = \frac{1}{5} \frac{dx}{dt}.$$

Given that $\frac{dx}{dt} = 0.5 \text{ m/s}$, it follows that when $x = 4 \text{ m}$,

$$\cos \theta = \frac{4}{5} \quad \text{so that} \quad \sin \theta = \sqrt{1 - \left(\frac{4}{5}\right)^2} = \frac{3}{5}$$

and

$$-\frac{3}{5} \frac{d\theta}{dt} = \frac{1}{5}(0.5).$$

Therefore,

$$\frac{d\theta}{dt} = -\frac{1}{6}.$$

When the lower end of the ladder is 4 m from the wall, the inclination θ of the ladder is decreasing at a rate of $\boxed{\frac{1}{6} \text{ rad/s}}$.

20. Let x denote the distance from the man to the tower. Then

$$\tan \theta = \frac{23}{x} \quad \text{and} \quad \sec^2 \theta \frac{d\theta}{dt} = -\frac{23}{x^2} \frac{dx}{dt}.$$

Given that $\frac{dx}{dt} = -1$ m/s, it follows that when $x = 10$ m,

$$\tan \theta = \frac{23}{10} = 2.3 \quad \text{so that} \quad \sec^2 \theta = 1 + \tan^2 \theta = 1 + (2.3)^2 = 6.29$$

and

$$6.29 \frac{d\theta}{dt} = -\frac{23}{100}(-1) = 0.23.$$

Therefore,

$$\frac{d\theta}{dt} = \frac{0.23}{6.29} \approx 0.037.$$

When the man is 10 m from the tower, the angle of elevation is increasing at a rate of approximately 0.037 rad/s.

21. Let h denote the depth of the water in the pool at the deep end, and let L denote the horizontal length of the surface of the water at depth h (see the diagram below). By similar triangles

$$\frac{L}{h} = \frac{30}{2} = 15 \quad \text{so that} \quad L = 15h$$

and the volume of water in the pool is

$$V = \left(\frac{1}{2} Lh \right) (5) = \frac{5}{2} (15h)h = \frac{75}{2} h^2.$$

Differentiating with respect to time t yields

$$\frac{dV}{dt} = 75h \frac{dh}{dt} \quad \text{so} \quad \frac{dh}{dt} = \frac{1}{75h} \frac{dV}{dt}.$$

Given that $\frac{dV}{dt} = 15$ m³/min, it follows that when $h = 1$ m,

$$\frac{dh}{dt} = \frac{1}{75(1)} 15 = \frac{1}{5} = 0.2.$$

When the water level is 1 m deep at the deep end of the pool, the water level is rising at a rate of 0.2 m/min.

22. The volume V of water in a cylindrical tank with diameter 6 m (that is, the radius is 3 m) and depth h is $V = \pi(3)^2 h = 9\pi h$. Differentiating with respect to time t yields

$$\frac{dV}{dt} = 9\pi \frac{dh}{dt} \quad \text{or} \quad \frac{dh}{dt} = \frac{1}{9\pi} \frac{dV}{dt}.$$

Given that $\frac{dV}{dt} = 5 \text{ m}^3/\text{min}$, it follows that

$$\frac{dh}{dt} = \frac{1}{9\pi}(5) = \frac{5}{9\pi}.$$

The depth of the water is rising at a rate of $\boxed{\frac{5}{9\pi} \text{ m/min} \approx 0.177 \text{ m/min}}.$

23. The volume V of water in the shape of a cone with radius r and height h is $V = \frac{1}{3}\pi r^2 h$. Consider the diagram on the right in the text. By similar triangles

$$\frac{r}{h} = \frac{4}{16} = \frac{1}{4} \quad \text{so that} \quad r = \frac{1}{4}h$$

and

$$V = \frac{1}{3}\pi \left(\frac{1}{4}h\right)^2 h = \frac{1}{48}\pi h^3.$$

Differentiating with respect to time t yields

$$\frac{dV}{dt} = \frac{1}{16}\pi h^2 \frac{dh}{dt} \quad \text{or} \quad \frac{dh}{dt} = \frac{16}{\pi h^2} \frac{dV}{dt}.$$

Given that $\frac{dV}{dt} = 16 \text{ m}^3/\text{min}$, it follows that when $h = 8 \text{ m}$,

$$\frac{dh}{dt} = \frac{16}{\pi(8)^2}(16) = \frac{4}{\pi}.$$

When the water is 8 m deep, the water level is rising at a rate of $\boxed{\frac{4}{\pi} \text{ m/min} \approx 1.273 \text{ m/min}}.$

24. The volume V of sand in a conical pile of radius r and height h is $V = \frac{1}{3}\pi r^2 h$. If the height of the pile is always one-fourth the diameter, then the height is one-half the radius; in other words, the radius of the conical pile is always twice the height. Therefore,

$$V = \frac{1}{3}\pi(2h)^2 h = \frac{4}{3}\pi h^3.$$

Differentiating with respect to time t yields

$$\frac{dV}{dt} = 4\pi h^2 \frac{dh}{dt} \quad \text{or} \quad \frac{dh}{dt} = \frac{1}{4\pi h^2} \frac{dV}{dt}.$$

Given that $\frac{dV}{dt} = 20 \text{ cm}^3/\text{s}$, it follows that when $h = 3 \text{ cm}$,

$$\frac{dh}{dt} = \frac{1}{4\pi(3)^2}(20) = \frac{5}{9\pi}.$$

When the height of the sand pile is 3 cm, the height of the sand pile is increasing at a rate of

$$\boxed{\frac{5}{9\pi} \text{ cm/s} \approx 0.177 \text{ cm/s}}.$$

25. (a) The volume V of water in the shape of a cone with radius r and height h is $V = \frac{1}{3}\pi r^2 h$. By similar triangles (see the diagram below),

$$\frac{r}{h} = \frac{1}{4} \quad \text{so that} \quad r = \frac{1}{4}h$$

and

$$V = \frac{1}{3}\pi \left(\frac{1}{4}h\right)^2 h = \frac{1}{48}\pi h^3.$$

Differentiating with respect to time t yields

$$\frac{dV}{dt} = \frac{1}{16}\pi h^2 \frac{dh}{dt} \quad \text{or} \quad \frac{dh}{dt} = \frac{16}{\pi h^2} \frac{dV}{dt}.$$

Given that $\frac{dV}{dt} = 3 \text{ m}^3/\text{min}$, it follows that when $h = 3 \text{ m}$,

$$\frac{dh}{dt} = \frac{16}{\pi(3)^2}(3) = \frac{16}{3\pi}.$$

When the water in the tank is 3 m deep, the water level is rising at a rate of

$$\boxed{\frac{16}{3\pi} \text{ m/min} \approx 1.698 \text{ m/min}}.$$

- (b) Based on the observation that the depth of the water is increasing at only 0.5 m/min when the depth is 3 m, the rate at which the volume of water in the tank is increasing is

$$\frac{dV}{dt} = \frac{1}{16}\pi(3)^2(0.5) = \frac{9\pi}{32} \text{ m}^3/\text{min} \approx 0.884 \text{ m}^3/\text{min}.$$

Because water is entering the tank at a rate of 3 m³/min, the rate at which water is leaking from the tank is

$$3 - \frac{9\pi}{32} = \boxed{\frac{96 - 9\pi}{32} \text{ m}^3/\text{min} \approx 2.116 \text{ m}^3/\text{min}}.$$

26. As a function of x , the area A of the rectangle is $A = xe^x$. Differentiating with respect to time t then yields

$$\frac{dA}{dt} = xe^x \frac{dx}{dt} + e^x \frac{dx}{dt} = e^x(x+1) \frac{dx}{dt}.$$

Given that $\frac{dx}{dt} = 1$ unit per second, it follows that when $x = 10$ units,

$$\frac{dA}{dt} = e^{10}(11)(1) = 11e^{10}.$$

When $x = 10$ units, the area of the rectangle is increasing at a rate of

$$\boxed{11e^{10} \text{ units}^2/\text{s} \approx 242,291.124 \text{ units}^2/\text{s}}.$$

27. Let (x, y) be a point on the graph of the parabola $y^2 = 4(3 - x) = 12 - 4x$. The distance D from the point (x, y) to the origin is

$$D = \sqrt{x^2 + y^2} = \sqrt{x^2 - 4x + 12}.$$

Differentiating both the equation of the parabola and the distance formula with respect to time t yields

$$2y \frac{dy}{dt} = -4 \frac{dx}{dt} \quad \text{or} \quad \frac{dx}{dt} = -\frac{y}{2} \frac{dy}{dt}$$

and

$$\frac{dD}{dt} = \frac{1}{2}(x^2 - 4x + 12)^{-1/2}(2x - 4) \frac{dx}{dt} = \frac{x - 2}{\sqrt{x^2 - 4x + 12}} \frac{dx}{dt}.$$

Given that $\frac{dy}{dt} = 3$ units per second when the object is at the point $(-1, 4)$, it follows that when the object is at the point $(-1, 4)$,

$$\frac{dx}{dt} = -\frac{4}{2}(3) = -6 \text{ units per second,}$$

and

$$\frac{dD}{dt} = \frac{-1 - 2}{\sqrt{1 + 4 + 12}}(-6) = \frac{18}{\sqrt{17}}.$$

When the object is at the point $(-1, 4)$, the distance between the object and the origin is increasing at a rate of $\frac{18}{\sqrt{17}}$ units per second ≈ 4.366 units per second.

28. The volume V of liquid in the shape of a cone with radius r and height h is $V = \frac{1}{3}\pi r^2 h$. By similar triangles (see the diagram below),

$$\frac{r}{h} = \frac{7.5}{15} = \frac{1}{2} \quad \text{so that} \quad r = \frac{1}{2}h$$

and

$$V = \frac{1}{3}\pi \left(\frac{1}{2}h\right)^2 h = \frac{1}{12}\pi h^3.$$

Differentiating with respect to time t yields

$$\frac{dV}{dt} = \frac{1}{4}\pi h^2 \frac{dh}{dt} \quad \text{or} \quad \frac{dh}{dt} = \frac{4}{\pi h^2} \frac{dV}{dt}.$$

Given that $\frac{dV}{dt} = -5 \text{ cm}^3/\text{min}$, it follows that when $h = 8 \text{ cm}$,

$$\frac{dh}{dt} = \frac{4}{\pi(8)^2}(-5) = -\frac{5}{16\pi}.$$

When the depth of the liquid is 8 cm, the depth of the liquid is decreasing at a rate of

$\frac{5}{16\pi} \text{ cm/min} \approx 0.099 \text{ cm/min}$.

29. The distance x between the ball and first base is

$$x = \sqrt{s^2 + 90^2} = \sqrt{s^2 + 8100},$$

where s is the distance between the ball and home plate along the third-base line. Differentiating with respect to time t yields

$$\frac{dx}{dt} = \frac{1}{2}(s^2 + 8100)^{-1/2}(2s)\frac{ds}{dt} = \frac{s}{\sqrt{s^2 + 8100}} \frac{ds}{dt}.$$

Given that $\frac{ds}{dt} = 100$ ft/s, it follows that when the ball crosses third base ($s = 90$ ft),

$$\frac{dx}{dt} = \frac{90}{\sqrt{90^2 + 8100}}(100) = \frac{100}{\sqrt{2}} = 50\sqrt{2}.$$

When the ball crosses third base, the distance from the ball to first base is increasing at a rate of $50\sqrt{2}$ ft/s ≈ 70.711 ft/s.

30. Let x denote the horizontal distance between the falcon and the falconer, and let y denote the height of the falcon. With a speed of 88 ft/s, the falcon flies the first 200 ft in

$$\frac{200}{88} = \frac{25}{11} \text{ seconds.}$$

During these first $25/11$ seconds of flight, the falcon is traveling at an angle of 60° , so

$$x = 88(\cos 60^\circ)t = 44t \quad \text{and} \quad y = 88(\sin 60^\circ)t = 44t\sqrt{3}.$$

When the falcon levels off, it has traveled

$$44 \cdot \frac{25}{11} = 100 \text{ feet}$$

horizontally, and

$$44 \cdot \frac{25}{11} \cdot \sqrt{3} = 100\sqrt{3} \text{ feet}$$

vertically. Thereafter, the falcon maintains a constant height, so that

$$x = \begin{cases} 44t, & 0 \leq t \leq \frac{25}{11} \\ 100 + 88t, & t > \frac{25}{11} \end{cases} \quad \text{and} \quad y = \begin{cases} 44t\sqrt{3}, & 0 \leq t \leq \frac{25}{11} \\ 100\sqrt{3}, & t > \frac{25}{11}. \end{cases}$$

Now, let $D = \sqrt{x^2 + y^2}$ be the distance between the falcon and the falconer. Then

$$\frac{dD}{dt} = \frac{1}{2}(x^2 + y^2)^{-1/2} \left(2x \frac{dx}{dt} + 2y \frac{dy}{dt} \right) = \frac{x \frac{dx}{dt} + y \frac{dy}{dt}}{\sqrt{x^2 + y^2}}.$$

At $t = 6$ seconds, $x = 100 + 88(6) = 628$ ft, $y = 100\sqrt{3}$ ft, $\frac{dx}{dt} = 88$ ft/s, and $\frac{dy}{dt} = 0$ ft/s, so

$$\frac{dD}{dt} = \frac{628(88) + 0}{\sqrt{628^2 + (100\sqrt{3})^2}} \approx 84.833.$$

After the falcon has been in flight for 6 seconds, the falcon is moving away from the falconer at a rate of approximately 84.833 ft/s.

31. Differentiating the equation $PV^{1.4} = k$ with respect to time t yields

$$P \cdot 1.4V^{0.4} \frac{dV}{dt} + V^{1.4} \frac{dP}{dt} = 0$$

so that

$$\frac{dP}{dt} = -\frac{1.4PV^{0.4}}{V^{1.4}} \frac{dV}{dt} = -\frac{1.4P}{V} \frac{dV}{dt}.$$

Given that $\frac{dV}{dt} = -2 \text{ cm}^3/\text{min}$ at the instant when $P = 20 \text{ kg/cm}^2$ and $V = 32 \text{ cm}^3$, it follows that

$$\frac{dP}{dt} = -\frac{1.4(20)}{32}(-2) = \frac{28}{16} = 1.75.$$

At the instant when $P = 20 \text{ kg/cm}^2$ and $V = 32 \text{ cm}^3$, the pressure is increasing at a rate of

$$\boxed{1.75 \frac{\text{kg/cm}^2}{\text{min}}}.$$

32. The area A of a circle of radius r is $A = \pi r^2$. Differentiating with respect to time t yields

$$\frac{dA}{dt} = 2\pi r \frac{dr}{dt}.$$

Given that $\frac{dr}{dt} = 0.02 \text{ cm/s}$, it follows that when $r = 3 \text{ cm}$,

$$\frac{dA}{dt} = 2\pi(3)(0.02) = 0.12\pi.$$

When the radius of the plate is 3 cm, the area of the top surface of the plate is increasing at a rate of

$$\boxed{0.12\pi \text{ cm}^2/\text{s} \approx 0.377 \text{ cm}^2/\text{s}}.$$

33. The area A of a circle of radius r is $A = \pi r^2$. Differentiating with respect to time t yields

$$\frac{dA}{dt} = 2\pi r \frac{dr}{dt}.$$

Given that $\frac{dr}{dt} = 0.42 \text{ ft/min}$, it follows that when $r = 120 \text{ ft}$,

$$\frac{dA}{dt} = 2\pi(120)(0.42) = 100.8\pi.$$

When the radius of the oil spill is 120 ft, the area of the spill is increasing at a rate of

$$\boxed{100.8\pi \text{ ft}^2/\text{min} \approx 316.673 \text{ ft}^2/\text{min}}.$$

34. Let L denote the length of the string released and x denote the horizontal distance from the kite to the girl. Then $L^2 = 30^2 + x^2 = 900 + x^2$. Differentiating with respect to time t yields

$$2L \frac{dL}{dt} = 2x \frac{dx}{dt} \quad \text{so that} \quad \frac{dL}{dt} = \frac{x}{L} \frac{dx}{dt}.$$

Given that $\frac{dx}{dt} = 2 \text{ m/s}$, it follows that when $L = 70 \text{ m}$,

$$x = \sqrt{70^2 - 900} = \sqrt{4000} \text{ m},$$

and

$$\frac{dL}{dt} = \frac{\sqrt{4000}}{70}(2) = \frac{4\sqrt{10}}{7}.$$

When the length of the string released is 70 ft, the string is being let out at a rate of

$$\boxed{\frac{4\sqrt{10}}{7} \text{ m/s} \approx 1.807 \text{ m/s}}.$$

35. Let x denote the distance from the base of the ladder to the wall and y denote the distance up the wall from the top of the ladder to the ground. Then $x^2 + y^2 = 8^2 = 64$. Differentiating with respect to time t yields

$$2x \frac{dx}{dt} + 2y \frac{dy}{dt} = 0 \quad \text{or} \quad \frac{dy}{dt} = -\frac{x}{y} \frac{dx}{dt}.$$

- (a) Given that $\frac{dx}{dt} = 0.5$ m/s, it follows that when $x = 3$ m,

$$y = \sqrt{64 - 3^2} = \sqrt{55} \text{ m},$$

and

$$\frac{dy}{dt} = -\frac{3}{\sqrt{55}}(0.5) = -\frac{1.5}{\sqrt{55}}.$$

The top of the ladder is moving down the wall at a rate of $\frac{1.5}{\sqrt{55}} \text{ m/s} \approx 0.202 \text{ m/s}$.

- (b) Given that $\frac{dx}{dt} = 0.5$ m/s, it follows that when $x = 4$ m,

$$y = \sqrt{64 - 4^2} = \sqrt{48} = 4\sqrt{3} \text{ m},$$

and

$$\frac{dy}{dt} = -\frac{4}{4\sqrt{3}}(0.5) = -\frac{0.5}{\sqrt{3}}.$$

The top of the ladder is moving down the wall at a rate of $\frac{0.5}{\sqrt{3}} \text{ m/s} \approx 0.289 \text{ m/s}$.

- (c) Given that $\frac{dx}{dt} = 0.5$ m/s, it follows that when $x = 6$ m,

$$y = \sqrt{64 - 6^2} = \sqrt{28} = 2\sqrt{7} \text{ m},$$

and

$$\frac{dy}{dt} = -\frac{6}{2\sqrt{7}}(0.5) = -\frac{1.5}{\sqrt{7}}.$$

The top of the ladder is moving down the wall at a rate of $\frac{1.5}{\sqrt{7}} \text{ m/s} \approx 0.567 \text{ m/s}$.

36. Let x denote the distance from the point on the shore opposite the lighthouse to the point where the beam of light from the lighthouse touches the shoreline, and let θ denote the angle made by the beam and the perpendicular from the lighthouse to the shoreline (see the diagram below). Then

$$\frac{x}{2000} = \tan \theta \quad \text{so that} \quad \frac{1}{2000} \frac{dx}{dt} = \sec^2 \theta \frac{d\theta}{dt}.$$

Given that

$$\frac{d\theta}{dt} = 2 \frac{\text{revolutions}}{\text{minute}} \cdot \frac{2\pi \text{ rad}}{\text{revolution}} = 4\pi \frac{\text{rad}}{\text{minute}},$$

and $x = 500$ m, it follows that

$$\begin{aligned} \tan \theta &= \frac{500}{2000} = \frac{1}{4}, \\ \sec^2 \theta &= 1 + \tan^2 \theta = 1 + \left(\frac{1}{4}\right)^2 = \frac{17}{16}, \end{aligned}$$

and

$$\frac{dx}{dt} = 2000 \left(\frac{17}{16} \right) (4\pi) = 8500\pi.$$

When the beam passes a point 500 m from the point on the shore opposite the lighthouse, the beam is moving along the shore at a rate of $8500\pi \text{ m/min} \approx 26,703.538 \text{ m/min}$.

37. Let x denote the distance from the point on the shore opposite the ship to the point where the radar beam intersects the shoreline, and let θ denote the angle made by the beam and the perpendicular from the ship to the shoreline (see the diagram below). Then

$$\frac{x}{6} = \tan \theta \quad \text{so that} \quad \frac{1}{6} \frac{dx}{dt} = \sec^2 \theta \frac{d\theta}{dt}.$$

Given that

$$\frac{d\theta}{dt} = \frac{1 \text{ revolution}}{5 \text{ s}} \cdot \frac{2\pi \text{ rad}}{\text{revolution}} = \frac{2\pi}{5} \frac{\text{rad}}{\text{s}},$$

and $\theta = 45^\circ$, it follows that

$$\frac{dx}{dt} = 6 \sec^2 45^\circ \cdot \frac{2\pi}{5} = \frac{24\pi}{5}.$$

When the beam makes an angle of 45° with the shore, the beam is moving along the shore at a rate of

$$\frac{24\pi}{5} \text{ km/s} \approx 15.080 \text{ km/s}.$$

38. Let y denote the height of the rocket above the ground. Then

$$\tan \theta = \frac{y}{150} \quad \text{and} \quad \sec^2 \theta \frac{d\theta}{dt} = \frac{1}{150} \frac{dy}{dt}.$$

- (a) Just after launch, $y = 0$, so $\tan \theta = 0$ and $\sec^2 \theta = 1 + \tan^2 \theta = 1$. With $\frac{dy}{dt} = 2.0 \text{ m/s}$, it follows that

$$\frac{d\theta}{dt} = \frac{1}{150 \sec^2 \theta} \frac{dy}{dt} = \frac{1}{150} (2.0) = \frac{1}{75}.$$

Just after launch, the angle of elevation of the tracking dish is increasing at a rate of

$$\boxed{\frac{1}{75} \text{ rad/s} \approx 0.0133 \text{ rad/s}}.$$

- (b) When the rocket is 100 m above the ground, $y = 100$, so

$$\tan \theta = \frac{100}{150} = \frac{2}{3} \quad \text{and} \quad \sec^2 \theta = 1 + \tan^2 \theta = \frac{13}{9}.$$

With $\frac{dy}{dt} = 2.0$ m/s, it follows that

$$\frac{d\theta}{dt} = \frac{1}{150 \sec^2 \theta} \frac{dy}{dt} = \frac{1}{150(13/9)} (2.0) = \frac{18}{1950}.$$

When the rocket is 100 m above the ground, the angle of elevation of the tracking dish is increasing

at a rate of $\boxed{\frac{18}{1950} \text{ rad/s} \approx 0.00923 \text{ rad/s}}.$

- (c) When the rocket is 1.0 km above the ground, $y = 1000$, so

$$\tan \theta = \frac{1000}{150} = \frac{20}{3} \quad \text{and} \quad \sec^2 \theta = 1 + \tan^2 \theta = \frac{409}{9}.$$

With $\frac{dy}{dt} = 2.0$ m/s, it follows that

$$\frac{d\theta}{dt} = \frac{1}{150 \sec^2 \theta} \frac{dy}{dt} = \frac{1}{150(409/9)} (2.0) = \frac{18}{61350}.$$

When the rocket is 1 km above the ground, the angle of elevation of the tracking dish is increasing

at a rate of $\boxed{\frac{18}{61350} \text{ rad/s} \approx 0.000293 \text{ rad/s}}.$

- (d) Based on the results from parts (a), (b), and (c), $\boxed{\text{the tracking rate decreases with increasing height of the rocket. In the limit as the rocket gets extremely high (that is, as } \theta \rightarrow \pi/2), \tan \theta \rightarrow \infty \text{ so } \sec^2 \theta \rightarrow \infty \text{ and } \frac{d\theta}{dt} \rightarrow 0}.$

39. Let x denote the horizontal distance from the boy to the street lamp, and let s denote the length of the boy's shadow (see the diagram below). By similar triangles

$$\frac{s}{1} = \frac{x+s}{6} \quad \text{so that} \quad 6s = x+s \quad \text{or} \quad s = \frac{1}{5}x.$$

Therefore,

$$\frac{ds}{dt} = \frac{1}{5} \frac{dx}{dt},$$

and with $\frac{dx}{dt} = 20$ m/min,

$$\frac{ds}{dt} = \frac{1}{5}(20) = 4.$$

The child's shadow is lengthening at a rate of $\boxed{4 \text{ m/min}}.$

40. Let x denote the distance from the boy's feet to the base of the pole. Then, the distance D from the boy's feet to the top of the pole is given by

$$D = \sqrt{x^2 + 20^2} = \sqrt{x^2 + 400}.$$

Differentiating with respect to time t yields

$$\frac{dD}{dt} = \frac{1}{2}(x^2 + 400)^{-1/2}(2x)\frac{dx}{dt} = \frac{x}{\sqrt{x^2 + 400}} \frac{dx}{dt}.$$

Given that

$$\frac{dx}{dt} = -4 \frac{\text{km}}{\text{h}} \cdot \frac{1000 \text{ m}}{1 \text{ km}} \cdot \frac{1 \text{ h}}{3600 \text{ s}} = -\frac{10}{9} \frac{\text{m}}{\text{s}},$$

where the derivative is negative because the boy is walking toward the pole, it follows that when $x = 5 \text{ m}$,

$$\frac{dD}{dt} = \frac{5}{\sqrt{5^2 + 400}} \left(-\frac{10}{9} \right) \approx -0.269.$$

When the boy is 5 m from the pole, the distance from his feet to the top of the pole is decreasing at a rate of approximately $\boxed{0.269 \text{ m/s}}$.

41. Place the center of the ferris wheel at the point $(0, 30)$, and suppose that the ferris wheel rotates counterclockwise. Then the x - and y -coordinates of a passenger on the ferris wheel can be modeled by

$$x = 25 \cos \theta \quad \text{and} \quad y = 30 + 25 \sin \theta.$$

When a passenger is 42.5 ft above the ground,

$$42.5 = 30 + 25 \sin \theta \quad \text{so that} \quad \sin \theta = \frac{1}{2}.$$

Given that the passenger is rising, $\theta = 30^\circ$. Moreover, with

$$\frac{d\theta}{dt} = \frac{1 \text{ revolution}}{2 \text{ min}} \cdot \frac{2\pi \text{ rad}}{\text{revolution}} = \pi \frac{\text{rad}}{\text{min}},$$

it follows that

$$\frac{dy}{dt} = 25 \cos \theta \frac{d\theta}{dt} = 25\pi \cos 30^\circ = \frac{25\pi\sqrt{3}}{2} \text{ ft/min} \approx 68.017 \text{ ft/min}.$$

Additionally,

$$\frac{dx}{dt} = -25 \sin \theta \frac{d\theta}{dt} = -25\pi \sin 30^\circ = -\frac{25\pi}{2} \text{ ft/min} \approx -39.270 \text{ ft/min}.$$

The passenger is rising at a rate of $\boxed{\frac{25\pi\sqrt{3}}{2} \text{ ft/min} \approx 68.017 \text{ ft/min}}$ and is moving horizontally backward at a rate of $\boxed{\frac{25\pi}{2} \text{ ft/min} \approx 39.270 \text{ ft/min}}$.

42. Let x denote the distance from the intersection of the car traveling east, and y denote the distance from the intersection of the car traveling south. The distance D between the cars is then given by $D = \sqrt{x^2 + y^2}$, and

$$\frac{dD}{dt} = \frac{1}{2}(x^2 + y^2)^{-1/2} \left(2x \frac{dx}{dt} + 2y \frac{dy}{dt} \right) = \frac{x \frac{dx}{dt} + y \frac{dy}{dt}}{\sqrt{x^2 + y^2}}.$$

Given that $\frac{dx}{dt} = -30 \text{ km/h}$, $\frac{dy}{dt} = -40 \text{ km/h}$, $x = 100 \text{ m} = 0.1 \text{ km}$, and $y = 75 \text{ m} = 0.075 \text{ km}$, it follows that

$$\frac{dD}{dt} = \frac{0.1 \cdot -30 + 0.075 \cdot -40}{\sqrt{0.1^2 + 0.075^2}} = -48 \text{ km/h}.$$

The cars are approaching one another at a rate of $\boxed{48 \text{ km/h}}$.

43. Let x denote the horizontal distance between the delivery truck and the elevator, and let h denote the elevation of the elevator. The distance D between the delivery truck and the elevator is then given by $D = \sqrt{x^2 + h^2}$, and

$$\frac{dD}{dt} = \frac{1}{2}(x^2 + h^2)^{-1/2} \left(2x \frac{dx}{dt} + 2h \frac{dh}{dt} \right) = \frac{x \frac{dx}{dt} + h \frac{dh}{dt}}{\sqrt{x^2 + h^2}}.$$

One second after the elevator and delivery truck begin moving, $x = 8$ m and $h = 20$ m. Given that $\frac{dx}{dt} = 8$ m/s and $\frac{dh}{dt} = -5$ m/s, it follows that

$$\frac{dD}{dt} = \frac{8 \cdot 8 + 20 \cdot -5}{\sqrt{8^2 + 20^2}} = -\frac{9}{\sqrt{29}} = -\frac{9\sqrt{29}}{\sqrt{29}} \text{ m/s} \approx -1.671 \text{ m/s}.$$

The elevator and the delivery truck are separating at a rate of $-\frac{9\sqrt{29}}{\sqrt{29}}$ m/s ≈ -1.671 m/s; that is,

they are approaching one another at a rate of $\frac{9\sqrt{29}}{\sqrt{29}}$ m/s ≈ 1.671 m/s.

44. Let x denote the horizontal distance between the person and the pulley, and let h denote the distance through which the container has been lifted. Given that the person holds the end of the rope and walks away from an initial position beneath the pulley, the rope has length 20 m. The right triangle formed by the pulley, the person's hand and the initial location of the top of the container therefore has hypotenuse of length $10 + h$ and legs of length x and 10. Therefore,

$$(10 + h)^2 = x^2 + 10^2,$$

and

$$2(10 + h) \frac{dh}{dt} = 2x \frac{dx}{dt} \quad \text{or} \quad \frac{dh}{dt} = \frac{x}{10 + h} \frac{dx}{dt}.$$

When the person is 5 m away from the container, $x = 5$ and

$$h = \sqrt{x^2 + 10^2} - 10 = \sqrt{125} - 10 = 5\sqrt{5} - 10.$$

Given that $\frac{dx}{dt} = 2$ m/s, it follows that

$$\frac{dh}{dt} = \frac{5}{10 + 5\sqrt{5} - 10} (2) = \frac{2}{\sqrt{5}}.$$

When the person is 5 m away, the container is rising at a rate of $\frac{2}{\sqrt{5}}$ m/s ≈ 0.894 m/s.

45. (a) Differentiating $C = 10,000 + 3x$ with respect to time t yields

$$\frac{dC}{dt} = 3 \frac{dx}{dt}.$$

When $x = 1000$ switches and $\frac{dx}{dt} = 50$ switches per day,

$$\frac{dC}{dt} = 3(50) = 150.$$

When production is 1000 switches per day, cost increases at a rate of \$150/day.

(b) Differentiating

$$R = 5x - \frac{x^2}{2000}$$

with respect to time t yields

$$\frac{dR}{dt} = \left(5 - \frac{x}{1000}\right) \frac{dx}{dt}.$$

When $x = 1000$ switches and $\frac{dx}{dt} = 50$ switches per day,

$$\frac{dR}{dt} = \left(5 - \frac{1000}{1000}\right) \cdot 50 = 200.$$

When production is 1000 switches per day, revenue increases at a rate of $\boxed{\$200/\text{day}}$.

(c) Let P denote profit, so that $P = R - C$ and

$$\frac{dP}{dt} = \frac{dR}{dt} - \frac{dC}{dt}.$$

When $x = 1000$ switches and $\frac{dx}{dt} = 50$ switches per day,

$$\frac{dP}{dt} = 200 - 150 = 50,$$

based on the answers from parts (a) and (b). When production is 1000 switches per day, profit increases at a rate of $\boxed{\$50/\text{day}}$.

46. (a) With $R = \frac{2Gm}{c^2}$ and G and c constant,

$$\frac{dR}{dt} = \frac{2G}{c^2} \frac{dm}{dt}.$$

Given that $\frac{dm}{dt} = 1.99 \times 10^{30}$ kg/yr, it follows that

$$\frac{dR}{dt} = \frac{2(6.67 \times 10^{-11})}{(3.00 \times 10^8)^2} \cdot 1.99 \times 10^{30} \approx 2949.622.$$

If one of these huge black holes swallows one Sun-like star per year, the event horizon grows at a rate of approximately $\boxed{2949.622 \text{ m/yr} \approx 2.95 \text{ km/yr}}$.

(b) Using differentials,

$$\frac{|\Delta R|}{R} \approx \frac{|dR|}{R} = \frac{\frac{2G}{c^2} |dm|}{\frac{2Gm}{c^2}} = \frac{|dm|}{m}.$$

Assuming m is the mass of 10 billion Suns and $dm = 1$ Sun, the percentage increase in the event horizon each year is

$$\frac{|dm|}{m} \times 100\% = \frac{1}{10^{10}} \times 100\% = \boxed{10^{-8}\%}.$$

47. Because the object weighs 1000 lb on Earth's surface, $K = 1000$, and

$$W = 1000 \left(\frac{3960}{3960 + R} \right)^2 = 1000(3960)^2(3960 + R)^{-2}.$$

Differentiating with respect to time t then yields

$$\frac{dW}{dt} = -2000(3960)^2(3960 + R)^{-3} \frac{dR}{dt}.$$

Given that $\frac{dR}{dt} = 10$ mi/s, it follows that when $R = 50$ mi,

$$\frac{dW}{dt} = -2000 \frac{3960^2}{(3960 + 50)^3} (10) \approx -4.864.$$

When the object is 50 mi above Earth's surface, the weight of the object is decreasing at a rate of approximately $\boxed{-4.864 \text{ lb/s}}$.

48. (a) Let $x = \cos \theta + \sqrt{16 - \sin^2 \theta}$. Differentiating with respect to time t ,

$$\frac{dx}{dt} = -\sin \theta \frac{d\theta}{dt} + \frac{1}{2}(16 - \sin^2 \theta)^{-1/2}(-2 \sin \theta \cos \theta) \frac{d\theta}{dt} = -\left(1 + \frac{\cos \theta}{\sqrt{16 - \sin^2 \theta}}\right) \sin \theta \frac{d\theta}{dt}.$$

Given that $\frac{d\theta}{dt} = 45$ rad/s, it follows that when $\theta = \pi/6$ rad,

$$\frac{dx}{dt} = -\left(1 + \frac{\frac{\sqrt{3}}{2}}{\sqrt{16 - \frac{1}{4}}}\right) \cdot \frac{1}{2}(45) \approx 27.410.$$

When $\theta = \frac{\pi}{6}$, the speed of the piston head is approximately $\boxed{27.410 \text{ m/s}}$.

- (b) The figure below displays the graph of x as a function of θ . Based on the graph, the maximum distance of the piston head from the center of the crank shaft is $\boxed{5 \text{ m}}$, and the minimum distance is $\boxed{3 \text{ m}}$.

49. Using the diagram in the text,

$$\cot \theta = \frac{x}{4500},$$

so that

$$-\csc^2 \theta \frac{d\theta}{dt} = \frac{1}{4500} \frac{dx}{dt} \quad \text{or} \quad \frac{dx}{dt} = -4500 \csc^2 \theta \frac{d\theta}{dt}.$$

Given that $\frac{d\theta}{dt} = 1^\circ/\text{s} = \frac{\pi}{180}$ rad/s, it follows that when $\theta = 30^\circ$,

$$\frac{dx}{dt} = -4500 \cdot 4 \cdot \frac{\pi}{180} = -100\pi.$$

The plane is approaching the battery at a rate of $\boxed{100\pi \text{ ft/s} \approx 314.159 \text{ ft/s}}$.

50. Let h denote the elevation of the balloon, and let θ denote the angle of elevation of the observer's line of sight. Then

$$\tan \theta = \frac{h}{200} \quad \text{so that} \quad \sec^2 \theta \frac{d\theta}{dt} = \frac{1}{200} \frac{dh}{dt}.$$

When the balloon is 600 m high, $h = 600$ and $\tan \theta = 3$ so

$$\sec^2 \theta = 1 + \tan^2 \theta = 1 + 3^2 = 10.$$

Given that $\frac{dh}{dt} = 100$ m/min, it follows that

$$\frac{d\theta}{dt} = \frac{1}{200 \sec^2 \theta} \frac{dh}{dt} = \frac{1}{200(10)} \cdot 100 = \frac{1}{20}.$$

When the balloon is 600 m high, the angle of elevation of the observer's line of sight increases at a rate of $\boxed{\frac{1}{20} \text{ rad/min} = 0.05 \text{ rad/min}}.$

51. Let x denote the horizontal distance between the searchlight and the plane. Then

$$\cot \theta = \frac{x}{3000 \text{ ft}} \cdot \frac{5280 \text{ ft}}{\text{mi}} = 1.76x,$$

so that

$$-\csc^2 \theta \frac{d\theta}{dt} = 1.76 \frac{dx}{dt} \quad \text{or} \quad \frac{d\theta}{dt} = -\frac{1.76}{\csc^2 \theta} \frac{dx}{dt}.$$

When the distance between the plane and the searchlight is 5000 ft, then $x = 4000$ ft and $\cot \theta = 4/3$ so

$$\csc^2 \theta = 1 + \cot^2 \theta = 1 + \left(\frac{4}{3}\right)^2 = 1 + \frac{16}{9} = \frac{25}{9}.$$

Given that $\frac{dx}{dt} = 500$ mi/h, it follows that

$$\frac{d\theta}{dt} = -\frac{1.76}{25/9}(500) = -316.8.$$

When the distance between the searchlight and the plane is 5000 ft, the searchlight is turning at a rate of $\boxed{-316.8 \text{ rad/h} = -0.088 \text{ rad/s}}.$

52. Let x denote the distance from the police car to the intersection, and let y denote the distance from the suspect car to the intersection. Then

$$\tan \theta = \frac{y}{x}.$$

Differentiating with respect to time t yields

$$\sec^2 \theta \frac{d\theta}{dt} = \frac{x \frac{dy}{dt} - y \frac{dx}{dt}}{x^2},$$

or

$$\frac{d\theta}{dt} = \frac{x \frac{dy}{dt} - y \frac{dx}{dt}}{x^2 \sec^2 \theta}.$$

Two seconds after the suspect car has crossed the intersection, $x = 210 - 2(80) = 50$ ft, $y = 2(60) = 120$ ft, $\tan \theta = 120/50 = 2.4$, and

$$\sec^2 \theta = 1 + \tan^2 \theta = 1 + (2.4)^2 = 6.76.$$

Given that $\frac{dx}{dt} = -80$ ft/s and $\frac{dy}{dt} = 60$ ft/s, it follows that

$$\frac{d\theta}{dt} = \frac{50 \cdot 60 - 120 \cdot (-80)}{50^2(6.76)} \approx 0.746.$$

In order to follow the suspicious vehicle, the light beam must be turning at a rate of approximately $\boxed{0.746 \text{ rad/s}}$.

53. Let $V = hx^2$.

(a) If h decreases with time but x remains constant, then

$$\frac{dV}{dt} = \boxed{x^2 \frac{dh}{dt}},$$

so that the volume of the box decreases at a rate x^2 time the rate of decrease in the height.

(b) If both h and x change with time, then

$$\frac{dV}{dt} = h \cdot 2x \frac{dx}{dt} + x^2 \frac{dh}{dt} = \boxed{2hx \frac{dx}{dt} + x^2 \frac{dh}{dt}}.$$

Answers will now vary. For example, note that the rate of change of the height is multiplied by the area of the square base while the rate of change of the side length of the base is multiplied by twice the area of the vertical sides.

54. Let $y = 2e^{\cos x}$. If both x and y vary with time, then

$$\frac{dy}{dt} = 2e^{\cos x}(-\sin x) \frac{dx}{dt} \quad \text{or} \quad \frac{dx}{dt} = -\frac{1}{2 \sin x e^{\cos x}} \frac{dy}{dt}.$$

Given that $\frac{dy}{dt} = 5$ units per second, it follows that when $x = \frac{\pi}{2}$,

$$\frac{dx}{dt} = -\frac{1}{2 \cdot 1 \cdot e^0}(5) = -\frac{5}{2}.$$

When $x = \frac{\pi}{2}$, x is decreasing at a rate of $\boxed{\frac{5}{2} \text{ units per second}}$.

Challenge Problems

55. Place the origin at the center of the dome, so the surface of the dome over which the shadow travels can be modeled by the equation $x^2 + y^2 = 30^2 = 900$. As the shadow of the ball moves along the surface of the dome,

$$2x \frac{dx}{dt} + 2y \frac{dy}{dt} = 0 \quad \text{or} \quad \frac{dx}{dt} = -\frac{y}{x} \frac{dy}{dt},$$

and the speed with which the shadow is moving is

$$\begin{aligned} \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} &= \sqrt{1 + \frac{y^2}{x^2}} \left| \frac{dy}{dt} \right| \\ &= \sqrt{\frac{x^2 + y^2}{x^2}} \left| \frac{dy}{dt} \right| = \frac{30}{\sqrt{900 - y^2}} \left| \frac{dy}{dt} \right|. \end{aligned}$$

Because it is sunset, the rays from the sun are traveling parallel to the ground, and the y -coordinate of the shadow is the same as the y -coordinate of the ball itself. Let $t = 0$ denote the time when the ball begins falling. Then the y -coordinate of the ball (and of the shadow) is given by $y = 30 - 16t^2$, and

$$\frac{dy}{dt} = -32t.$$

At $t = 1/2$ s, $y = 30 - 16(1/4) = 26$ ft, $\frac{dy}{dt} = -16$ ft/s, and the speed of the shadow is

$$\frac{30}{\sqrt{900 - 26^2}} |-16| \approx \boxed{32.071 \text{ ft/s}}.$$

56. Because the sun is rising in the east and the wall of the station runs north-south, the speed with which the shadow of the train moves along the wall of the station is equal to the rate of change in the y -coordinate of the train as it moves along the track. Given that $y^2 = 600x$ along the track, it follows that

$$2y \frac{dy}{dt} = 600 \frac{dx}{dt} \quad \text{or} \quad \frac{dx}{dt} = \frac{y}{300} \frac{dy}{dt}.$$

The speed with which the train moves along the track is

$$\sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} = \sqrt{1 + \frac{y^2}{300^2}} \left| \frac{dy}{dt} \right|.$$

At the instant the shadow of the train reaches the end of the station wall, $y = 400$ ft and the speed of the train along the track is 15 mi/h, so

$$\sqrt{1 + \frac{400^2}{300^2}} \left| \frac{dy}{dt} \right| = 15$$

and

$$\left| \frac{dy}{dt} \right| = \frac{15}{\sqrt{1 + \frac{16}{9}}} = 15 \cdot \frac{3}{5} = 9 \text{ mi/h}.$$

Because the train is traveling in a northeasterly direction, the shadow is moving north at 9 mi/h as it reaches the end of the station wall.

57. The area A of the triangle OAB is

$$A = \frac{1}{2}(2)(3) \sin \theta = 3 \sin \theta,$$

where θ is the angle between the two hands of the clock. Now the hour hand moves one-twelfth of the circle in 60 minutes, so it moves at a rate of

$$\frac{1}{12} \cdot 2\pi \cdot \frac{1}{60} = \frac{\pi}{360} \text{ rad/min},$$

while the minute hand makes one revolution of the circle in 60 minutes, so it moves at a rate of

$$\frac{2\pi}{60} = \frac{\pi}{30} \text{ rad/min}.$$

At noon, the hour hand and the minute hand overlay, so ten minutes later the angle between the hands is

$$\theta = \frac{\pi}{30} \cdot 10 - \frac{\pi}{360} \cdot 10 = \frac{\pi}{3} - \frac{\pi}{36} = \frac{11\pi}{36},$$

and the rate at which the angle θ is changing is

$$\frac{d\theta}{dt} = \frac{\pi}{30} - \frac{\pi}{360} = \frac{11\pi}{360} \text{ rad/min.}$$

At 12:10 p.m.,

$$\frac{dA}{dt} = 3 \cos \theta \frac{d\theta}{dt} = 3 \cos \frac{11\pi}{36} \cdot \frac{11\pi}{360} \approx 0.165;$$

that is, the area of the triangle is increasing at a rate of approximately $\boxed{0.165 \text{ in}^2/\text{min}}$.

58. Place the origin at the “intersection” of the track and the street, with the positive x -axis pointing along the track in the direction the train is traveling. Let $t = 0$ correspond to the time the car passes under the track, and note that at this time, the train has already traveled 125 feet (5 seconds at 25 ft/s) along the track. Therefore, the x -, y - and z -coordinates of the train at any time t are given by

$$x_T = 125 + 25t, \quad y_T = 0, \quad \text{and} \quad z_T = 20,$$

while the coordinates of the car are given by

$$x_C = 40 \cos(-30^\circ)t = 20\sqrt{3}t, \quad y_C = 40 \sin(-30^\circ)t = -20t, \quad \text{and} \quad z_C = 0.$$

The distance D between the train and the car is

$$\begin{aligned} D &= \sqrt{(x_T - x_C)^2 + (y_T - y_C)^2 + (z_T - z_C)^2} \\ &= \sqrt{(125 + 25t - 20\sqrt{3}t)^2 + (20t)^2 + 20^2} \\ &= \sqrt{125^2 + 20^2 + 250(25 - 20\sqrt{3})t + [(25 - 20\sqrt{3})^2 + 20^2]t^2} \\ &= \sqrt{16025 + (6250 - 5000\sqrt{3})t + (2225 - 1000\sqrt{3})t^2} \end{aligned}$$

and

$$\frac{dD}{dt} = \frac{6250 - 5000\sqrt{3} + 2(2225 - 1000\sqrt{3})t}{2\sqrt{16025 + (6250 - 5000\sqrt{3})t + (2225 - 1000\sqrt{3})t^2}}.$$

Therefore, at $t = 3$,

$$\begin{aligned} \frac{dD}{dt} &= \frac{6250 - 5000\sqrt{3} + 2(2225 - 1000\sqrt{3})(3)}{2\sqrt{16025 + (6250 - 5000\sqrt{3})(3) + (2225 - 1000\sqrt{3})(3)^2}} \\ &= \frac{19600 - 11000\sqrt{3}}{2\sqrt{54800 - 24000\sqrt{3}}} \approx 2.380 \text{ ft/s.} \end{aligned}$$

The train and the car are separating at a rate of approximately $\boxed{2.380 \text{ ft/s}}$.

4.2: Maximum and Minimum Values; Critical Numbers

Concepts and Vocabulary

1. False. Any function f that is defined **and continuous** on a closed interval $[a, b]$ will have both an absolute maximum value and an absolute minimum value.
2. A number c in the domain of a function f is called a (b) critical number of f if either $f'(c) = 0$ or $f'(c)$ does not exist.
3. False. At a critical number, there **may be** a local extreme value.
4. False. If a function f is continuous on a closed interval $[a, b]$, then its absolute maximum value is found **either** at a critical number **or at an endpoint of the interval**.
5. False. The Extreme Value Theorem tells us when the absolute maximum and absolute minimum **exist**.
6. False. If f is differentiable on the interval $(0, 4)$ and $f'(2) = 0$, then f **may have** a local maximum or a local minimum at 2.

Skill Building

7. For the function given in the graph,

x_1 :	neither
x_2 :	local maximum
x_3 :	local minimum and absolute minimum
x_4 :	neither
x_5 :	local maximum
x_6 :	neither
x_7 :	local minimum
x_8 :	absolute maximum

8. For the function given in the graph,

x_1 :	neither
x_2 :	local maximum
x_3 :	local maximum
x_4 :	local minimum
x_5 :	neither
x_6 :	local maximum
x_7 :	local minimum and absolute minimum
x_8 :	absolute maximum

9. The figure below displays the graph of a function with the following properties: domain $[0, 8]$, absolute maximum at 0, absolute minimum at 3, local minimum at 7.

10. The figure below displays the graph of a function with the following properties: domain $[-5, 5]$, absolute maximum at 3, absolute minimum at -3 .

11. The figure below displays the graph of a function with the following properties: domain $[3, 10]$ and no local extreme values.

12. The figure below displays the graph of a function with the following properties: no absolute extreme values, differentiable at 4 and a local minimum at 4, not differentiable at 0 but a local maximum at 0.

13. Let $f(x) = x^2 - 8x$. Because f is a polynomial function, it is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now

$$f'(x) = 2x - 8 = 2(x - 4) = 0$$

when $x = 4$. Therefore, $\boxed{4}$ is the only critical number of f .

14. Let $f(x) = 1 - 6x + x^2$. Because f is a polynomial function, it is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now

$$f'(x) = -6 + 2x = 2(x - 3) = 0$$

when $x = 3$. Therefore, $\boxed{3}$ is the only critical number of f .

15. Let $f(x) = x^3 - 3x^2$. Because f is a polynomial function, it is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now

$$f'(x) = 3x^2 - 6x = 3x(x - 2) = 0$$

when $x = 0$ and when $x = 2$. Therefore, $\boxed{0 \text{ and } 2}$ are the critical numbers of f .

16. Let $f(x) = x^3 - 6x$. Because f is a polynomial function, it is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now

$$f'(x) = 3x^2 - 6 = 3(x^2 - 2) = 0$$

when $x = \pm\sqrt{2}$. Therefore, $\boxed{-\sqrt{2} \text{ and } \sqrt{2}}$ are the critical numbers of f .

17. Let $f(x) = x^4 - 2x^2 + 1$. Because f is a polynomial function, it is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now

$$f'(x) = 4x^3 - 4x = 4x(x^2 - 1) = 4x(x - 1)(x + 1) = 0$$

when $x = 0$ and when $x = \pm 1$. Therefore, $\boxed{-1, 0, \text{ and } 1}$ are the critical numbers of f .

18. Let $f(x) = 3x^4 - 4x^3$. Because f is a polynomial function, it is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now

$$f'(x) = 12x^3 - 12x^2 = 12x^2(x - 1) = 0$$

when $x = 0$ and when $x = 1$. Therefore, $\boxed{0 \text{ and } 1}$ are the critical numbers of f .

19. Let $f(x) = x^{2/3}$. The domain of f is the set of all real numbers, and $f'(x) = \frac{2}{3}x^{-1/3}$. The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now, $f'(x)$ is never equal to 0, and $f'(x)$ does not exist at $x = 0$. Because $x = 0$ is in the domain of f , 0 is a critical number of f . Therefore, $\boxed{0}$ is the only critical number of f .

20. Let $f(x) = x^{1/3}$. The domain of f is the set of all real numbers, and $f'(x) = \frac{1}{3}x^{-2/3}$. The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now, $f'(x)$ is never equal to 0, and $f'(x)$ does not exist at $x = 0$. Because $x = 0$ is in the domain of f , 0 is a critical number of f . Therefore, $\boxed{0}$ is the only critical number of f .

21. Let $f(x) = 2\sqrt{x}$. The domain of f is the set $\{x|x \geq 0\}$, and $f'(x) = \frac{1}{\sqrt{x}}$. The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now, $f'(x)$ is never equal to 0, and $f'(x)$ does not exist at $x = 0$. Because $x = 0$ is in the domain of f , 0 is a critical number of f . Therefore, $\boxed{0}$ is the only critical number of f .

22. Let $f(x) = 4 - \sqrt{x}$. The domain of f is the set $\{x|x \geq 0\}$, and $f'(x) = -\frac{1}{2\sqrt{x}}$. The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now, $f'(x)$ is never equal to 0, and $f'(x)$ does not exist at $x = 0$. Because $x = 0$ is in the domain of f , 0 is a critical number of f . Therefore, $\boxed{0}$ is the only critical number of f .

23. Let $f(x) = x + \sin x$, and consider the interval $0 \leq x \leq \pi$. Because f is differentiable on $0 \leq x \leq \pi$, the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = 1 + \cos x = 0$$

when $\cos x = -1$. On the interval $0 \leq x \leq \pi$, $\cos x = -1$ when $x = \pi$. Therefore, $\boxed{\pi}$ is the only critical number of f on the interval $0 \leq x \leq \pi$.

24. Let $f(x) = x - \cos x$, and consider the interval $-\frac{\pi}{2} \leq x \leq \frac{\pi}{2}$. Because f is differentiable on $-\frac{\pi}{2} \leq x \leq \frac{\pi}{2}$, the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = 1 + \sin x = 0$$

when $\sin x = -1$. On the interval $-\frac{\pi}{2} \leq x \leq \frac{\pi}{2}$, $\sin x = -1$ when $x = -\frac{\pi}{2}$. Therefore, $\boxed{-\frac{\pi}{2}}$ is the only critical number of f on the interval $-\frac{\pi}{2} \leq x \leq \frac{\pi}{2}$.

25. Let $f(x) = x\sqrt{1-x^2}$. The domain of f is the set $\{x|-1 \leq x \leq 1\}$, and

$$\begin{aligned} f'(x) &= x \cdot \frac{1}{2}(1-x^2)^{-1/2}(-2x) + \sqrt{1-x^2} \\ &= -\frac{x^2}{\sqrt{1-x^2}} + \sqrt{1-x^2} = \frac{-x^2 + 1 - x^2}{\sqrt{1-x^2}} = \frac{1-2x^2}{\sqrt{1-x^2}}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now, $f'(x) = 0$ when $1 - 2x^2 = 0$, or when $x = \pm\frac{\sqrt{2}}{2}$, and $f'(x)$ does not exist when $1 - x^2 = 0$, or when $x = \pm 1$. All four

of these numbers are in the domain of f , so all four are critical numbers. Therefore, $\boxed{\pm 1 \text{ and } \pm\frac{\sqrt{2}}{2}}$ are critical numbers of f .

26. Let $f(x) = x^2\sqrt{2-x}$. The domain of f is the set $\{x|x \leq 2\}$, and

$$\begin{aligned} f'(x) &= x^2 \cdot \frac{1}{2}(2-x)^{-1/2}(-1) + 2x\sqrt{2-x} \\ &= -\frac{x^2}{2\sqrt{2-x}} + 2x\sqrt{2-x} = \frac{-x^2 + 4x(2-x)}{2\sqrt{2-x}} = \frac{8x - 5x^2}{2\sqrt{2-x}}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now, $f'(x) = 0$ when $8x - 5x^2 = x(8 - 5x) = 0$, or when $x = 0$ or $x = \frac{8}{5}$. On the other hand, $f'(x)$ does not exist when $2 - x = 0$, or when $x = 2$. All three of these numbers are in the domain of f , so all three are critical numbers. Therefore, $\boxed{0, \frac{8}{5}, \text{ and } 2}$ are critical numbers of f .

27. Let $f(x) = \frac{x^2}{x-1}$. The domain of f is the set $\{x|x \neq 1\}$, and

$$f'(x) = \frac{(x-1)(2x) - x^2}{(x-1)^2} = \frac{2x^2 - 2x - x^2}{(x-1)^2} = \frac{x^2 - 2x}{(x-1)^2}.$$

The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now, $f'(x) = 0$ when $x^2 - 2x = x(x-2) = 0$, or when $x = 0$ or $x = 2$. On the other hand, $f'(x)$ does not exist when $x-1 = 0$, or when $x = 1$. As $x = 1$ is not in the domain of f , 1 is not a critical number. Therefore, $\boxed{0 \text{ and } 2}$ are the critical numbers of f .

28. Let $f(x) = \frac{x}{x^2-1}$. The domain of f is the set $\{x|x \neq \pm 1\}$, and

$$f'(x) = \frac{(x^2-1) - x(2x)}{(x^2-1)^2} = \frac{x^2-1-2x^2}{(x^2-1)^2} = -\frac{1+x^2}{(x^2-1)^2}.$$

The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now, $f'(x)$ is never equal to zero, but $f'(x)$ does not exist at $x = \pm 1$. As neither $x = 1$ nor $x = -1$ are in the domain of f , neither number is a critical number. Therefore, f has $\boxed{\text{no critical numbers}}$.

29. Let $f(x) = (x+3)^2(x-1)^{2/3}$. The domain of f is the set of all real numbers, and

$$\begin{aligned} f'(x) &= (x+3)^2 \cdot \frac{2}{3}(x-1)^{-1/3} + (x-1)^{2/3} \cdot 2(x+3) \\ &= \frac{2(x+3)^2}{3(x-1)^{1/3}} + 2(x+3)(x-1)^{2/3} = \frac{2(x+3)^2 + 6(x+3)(x-1)}{3(x-1)^{1/3}} \\ &= \frac{2(x+3)[x+3+3(x-1)]}{3(x-1)^{1/3}} = \frac{8x(x+3)}{3(x-1)^{1/3}}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now, $f'(x) = 0$ when $8x(x+3) = 0$, or when $x = 0$ or $x = -3$. On the other hand, $f'(x)$ does not exist when $x-1 = 0$, or when $x = 1$. All three of these numbers are in the domain of f , so all three are critical numbers. Therefore, $\boxed{-3, 0, \text{ and } 1}$ are critical numbers of f .

30. Let $f(x) = (x-1)^2(x+1)^{1/3}$. The domain of f is the set of all real numbers, and

$$\begin{aligned} f'(x) &= (x-1)^2 \cdot \frac{1}{3}(x+1)^{-2/3} + (x+1)^{1/3} \cdot 2(x-1) \\ &= \frac{(x-1)^2}{3(x+1)^{2/3}} + 2(x-1)(x+1)^{1/3} = \frac{(x-1)^2 + 6(x-1)(x+1)}{3(x+1)^{2/3}} \\ &= \frac{(x-1)[x-1+6(x+1)]}{3(x+1)^{2/3}} = \frac{(x-1)(7x+5)}{3(x+1)^{2/3}}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now, $f'(x) = 0$ when $(x-1)(7x+5) = 0$, or when $x = 1$ or $x = -\frac{5}{7}$. On the other hand, $f'(x)$ does not exist when $x+1 = 0$, or when $x = -1$. All three of these numbers are in the domain of f , so all three are critical numbers.

Therefore, $\boxed{-1, -\frac{5}{7}, \text{ and } 1}$ are critical numbers of f .

31. Let $f(x) = \frac{(x-3)^{1/3}}{x-1}$. The domain of f is the set $\{x|x \neq 1\}$, and

$$\begin{aligned} f'(x) &= \frac{(x-1) \cdot \frac{1}{3}(x-3)^{-2/3} - (x-3)^{1/3}}{(x-1)^2} \cdot \frac{3(x-3)^{2/3}}{3(x-3)^{2/3}} \\ &= \frac{(x-1) - 3(x-3)}{3(x-1)^2(x-3)^{2/3}} = \frac{8-2x}{3(x-1)^2(x-3)^{2/3}}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now, $f'(x) = 0$ when $8 - 2x = 0$, or when $x = 4$. On the other hand, $f'(x)$ does not exist when $(x-1)^2(x-3)^{2/3} = 0$, or when $x = 1$ or $x = 3$. As $x = 1$ is not in the domain of f , 1 is not a critical number. Therefore, 3 and 4 are critical numbers of f .

32. Let $f(x) = \frac{(x+3)^{2/3}}{x+1}$. The domain of f is the set $\{x|x \neq -1\}$, and

$$\begin{aligned} f'(x) &= \frac{(x+1) \cdot \frac{2}{3}(x+3)^{-1/3} - (x+3)^{2/3}}{(x+1)^2} \cdot \frac{3(x+3)^{1/3}}{3(x+3)^{1/3}} \\ &= \frac{2(x+1) - 3(x+3)}{3(x+1)^2(x+3)^{1/3}} = -\frac{x+7}{3(x+1)^2(x+3)^{1/3}}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now, $f'(x) = 0$ when $x + 7 = 0$, or when $x = -7$. On the other hand, $f'(x)$ does not exist when $(x+1)^2(x+3)^{1/3} = 0$, or when $x = -1$ or $x = -3$. As $x = -1$ is not in the domain of f , -1 is not a critical number. Therefore, -7 and -3 are critical numbers of f .

33. Let $f(x) = \frac{\sqrt[3]{x^2-9}}{x}$. The domain of f is the set $\{x|x \neq 0\}$, and

$$\begin{aligned} f'(x) &= \frac{x \cdot \frac{1}{3}(x^2-9)^{-2/3}(2x) - \sqrt[3]{x^2-9}}{x^2} \cdot \frac{3(x^2-9)^{2/3}}{3(x^2-9)^{2/3}} \\ &= \frac{2x^2 - 3(x^2-9)}{3x^2(x^2-9)^{2/3}} = \frac{27-x^2}{3x^2(x^2-9)^{2/3}}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now, $f'(x) = 0$ when $27 - x^2 = 0$, or when $x = \pm\sqrt{27} = \pm 3\sqrt{3}$. On the other hand, $f'(x)$ does not exist when $x^2(x^2-9)^{2/3} = 0$, or when $x = 0$ or $x = \pm 3$. As $x = 0$ is not in the domain of f , 0 is not a critical number. Therefore, ± 3 and $\pm 3\sqrt{3}$ are critical numbers of f .

34. Let $f(x) = \frac{\sqrt[3]{4-x^2}}{x}$. The domain of f is the set $\{x|x \neq 0\}$, and

$$\begin{aligned} f'(x) &= \frac{x \cdot \frac{1}{3}(4-x^2)^{-2/3}(-2x) - \sqrt[3]{4-x^2}}{x^2} \cdot \frac{3(4-x^2)^{2/3}}{3(4-x^2)^{2/3}} \\ &= \frac{-2x^2 - 3(4-x^2)}{3x^2(4-x^2)^{2/3}} = \frac{x^2-12}{3x^2(4-x^2)^{2/3}}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now, $f'(x) = 0$ when $x^2 - 12 = 0$, or when $x = \pm\sqrt{12} = \pm 2\sqrt{3}$. On the other hand, $f'(x)$ does not exist when $x^2(4-x^2)^{2/3} = 0$, or when $x = 0$ or $x = \pm 2$. As $x = 0$ is not in the domain of f , 0 is not a critical number. Therefore, ± 2 and $\pm 2\sqrt{3}$ are critical numbers of f .

35. On the interval $[0, 1)$, $f(x) = 3x$ so $f'(x) = 3$. Because $f'(x)$ exists everywhere on the interval $[0, 1)$ and is never equal to 0, f has no critical numbers in $[0, 1)$. On the interval $(1, 2]$, $f(x) = 4 - x$, so

$f'(x) = -1$. Because $f'(x)$ exists everywhere on the interval $(1, 2]$ and is never equal to 0, f has no critical numbers in $(1, 2]$. At $x = 1$, the rule for f changes, so it is necessary to investigate the existence of $f'(1)$. Now,

$$\lim_{x \rightarrow 1^-} \frac{f(x) - f(1)}{x - 1} = \lim_{x \rightarrow 1^-} \frac{3x - 3}{x - 1} = \lim_{x \rightarrow 1^-} \frac{3(x - 1)}{x - 1} = \lim_{x \rightarrow 1^-} 3 = 3,$$

and

$$\lim_{x \rightarrow 1^+} \frac{f(x) - f(1)}{x - 1} = \lim_{x \rightarrow 1^+} \frac{(4 - x) - 3}{x - 1} = \lim_{x \rightarrow 1^+} \frac{-(x - 1)}{x - 1} = \lim_{x \rightarrow 1^+} -1 = -1.$$

Because these two one-sided limits are not equal, $f'(x)$ does not exist at $x = 1$. Therefore, $\boxed{1}$ is the only critical number of f .

36. On the interval $[0, 1)$, $f(x) = x^2$ so $f'(x) = 2x$. Because $f'(x)$ exists everywhere on the interval $[0, 1)$ but is equal to 0 at $x = 0$, 0 is a critical number in $[0, 1)$. On the interval $(1, 2]$, $f(x) = 1 - x^2$, so $f'(x) = -2x$. Because $f'(x)$ exists everywhere and is never equal to 0 on the interval $(1, 2]$, f has no critical numbers in $(1, 2]$. At $x = 1$, the rule for f changes, so it is necessary to investigate the existence of $f'(1)$. Now,

$$\lim_{x \rightarrow 1^-} f(x) = \lim_{x \rightarrow 1^-} x^2 = 1 \quad \text{and} \quad \lim_{x \rightarrow 1^+} f(x) = \lim_{x \rightarrow 1^+} (1 - x^2) = 0.$$

Because these two one-sided limits are not equal, f is not continuous at $x = 1$ and $f'(x)$ does not exist at $x = 1$. Therefore, $\boxed{0 \text{ and } 1}$ are the critical numbers of f .

37. Let $f(x) = x^2 - 8x$, and consider the closed interval $[-1, 10]$. Because f is continuous on this closed interval, the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute minimum on $[-1, 10]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, f is a polynomial function, so it is differentiable everywhere, which means that the critical numbers of f occur where $f'(x) = 0$. Moreover,

$$f'(x) = 2x - 8 = 2(x - 4) = 0$$

when $x = 4$. Therefore, 4 is the only critical number of f . Evaluating f at the endpoints of the interval $[-1, 10]$ and at the critical number 4 yields

$$\begin{aligned} f(-1) &= (-1)^2 - 8(-1) = 9 \\ f(4) &= 4^2 - 8(4) = -16 \\ f(10) &= 10^2 - 8(10) = 20. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[-1, 10]$ is $\boxed{20}$ (and this occurs at the endpoint $x = 10$), while the absolute minimum value of f is $\boxed{-16}$ (and this occurs at the critical number $x = 4$).

38. Let $f(x) = 1 - 6x + x^2$, and consider the closed interval $[0, 4]$. Because f is continuous on this closed interval, the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute minimum on $[0, 4]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, f is a polynomial function, so it is differentiable everywhere, which means that the critical numbers of f occur where $f'(x) = 0$. Moreover,

$$f'(x) = -6 + 2x = 2(x - 3) = 0$$

when $x = 3$. Therefore, 3 is the only critical number of f . Evaluating f at the endpoints of the interval $[0, 4]$ and at the critical number 3 yields

$$\begin{aligned} f(0) &= 1 - 6(0) + 0^2 = 1 \\ f(3) &= 1 - 6(3) + 3^2 = -8 \\ f(4) &= 1 - 6(4) + 4^2 = -7. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[0, 4]$ is $\boxed{1}$ (and this occurs at the endpoint $x = 0$), while the absolute minimum value of f is $\boxed{-8}$ (and this occurs at critical number $x = 3$).

39. Let $f(x) = x^3 - 3x^2$, and consider the closed interval $[1, 4]$. Because f is continuous on this closed interval, the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute minimum on $[1, 4]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, f is a polynomial function, so it is differentiable everywhere, which means that the critical numbers of f occur where $f'(x) = 0$. Moreover,

$$f'(x) = 3x^2 - 6x = 3x(x - 2) = 0$$

when $x = 0$ or $x = 2$. Therefore, 0 and 2 are the critical numbers of f ; however, $x = 0$ is not inside the interval $(1, 4)$, so this critical number can be excluded. Evaluating f at the endpoints of the interval $[1, 4]$ and at the critical number 2 yields

$$\begin{aligned} f(1) &= 1^3 - 3(1)^2 = -2 \\ f(2) &= 2^3 - 3(2)^2 = -4 \\ f(4) &= 4^3 - 3(4)^2 = 16. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[1, 4]$ is $\boxed{16}$ (and this occurs at the endpoint $x = 4$), while the absolute minimum value of f is $\boxed{-4}$ (and this occurs at critical number $x = 2$).

40. Let $f(x) = x^3 - 6x$, and consider the closed interval $[-1, 1]$. Because f is continuous on this closed interval, the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute minimum on $[-1, 1]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, f is a polynomial function, so it is differentiable everywhere, which means that the critical numbers of f occur where $f'(x) = 0$. Moreover,

$$f'(x) = 3x^2 - 6 = 3(x^2 - 2) = 0$$

when $x = \pm\sqrt{2}$. Therefore, $-\sqrt{2}$ and $\sqrt{2}$ are the critical numbers of f ; however, neither of these numbers is inside the interval $(-1, 1)$, so both can be excluded, leaving no critical numbers inside the open interval. Evaluating f at the endpoints of the interval $[-1, 1]$ yields

$$\begin{aligned} f(-1) &= (-1)^3 - 6(-1) = 5 \\ f(1) &= 1^3 - 6(1) = -5. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[-1, 1]$ is $\boxed{5}$ (and this occurs at the endpoint $x = -1$), while the absolute minimum value of f is $\boxed{-5}$ (and this occurs at the endpoint $x = 1$).

41. Let $f(x) = x^4 - 2x^2 + 1$, and consider the closed interval $[0, 2]$. Because f is continuous on this closed interval, the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute minimum on $[0, 2]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, f is a polynomial function, so it is differentiable everywhere, which means that the critical numbers of f occur where $f'(x) = 0$. Moreover,

$$f'(x) = 4x^3 - 4x = 4x(x^2 - 1) = 4x(x - 1)(x + 1) = 0$$

when $x = 0$ or $x = \pm 1$. Therefore, $-1, 0$ and 1 are the critical numbers of f ; however, of these numbers, only $x = 1$ is inside the open interval $(0, 2)$. Evaluating f at the endpoints of the interval $[0, 2]$ and at the critical number 1 yields

$$\begin{aligned} f(0) &= 1 \\ f(1) &= 1^4 - 2(1)^2 + 1 = 0 \\ f(2) &= 2^4 - 2(2)^2 + 1 = 9. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[0, 2]$ is $\boxed{9}$ (and this occurs at the endpoint $x = 2$), while the absolute minimum value of f is $\boxed{0}$ (and this occurs at the critical number $x = 1$).

42. Let $f(x) = 3x^4 - 4x^3$, and consider the closed interval $[-2, 0]$. Because f is continuous on this closed interval, the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute minimum on $[-2, 0]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, f is a polynomial function, so it is differentiable everywhere, which means that the critical numbers of f occur where $f'(x) = 0$. Moreover,

$$f'(x) = 12x^3 - 12x^2 = 12x^2(x - 1) = 0$$

when $x = 0$ or $x = 1$. Therefore, 0 and 1 are the critical numbers of f ; however, neither of these numbers is inside the interval $(-2, 0)$, leaving no critical numbers inside the open interval. Evaluating f at the endpoints of the interval $[0, 2]$ yields

$$\begin{aligned} f(-2) &= 3(-2)^4 - 4(-2)^3 = 80 \\ f(0) &= 0. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[-2, 0]$ is $\boxed{80}$ (and this occurs at the endpoint $x = -2$), while the absolute minimum value of f is $\boxed{0}$ (and this occurs at the endpoint $x = 0$).

43. Let $f(x) = x^{2/3}$, and consider the closed interval $[-1, 1]$. Because f is continuous on this closed interval, the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute minimum on $[-1, 1]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, the critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Moreover,

$$f'(x) = \frac{2}{3}x^{-1/3},$$

so $f'(x)$ is never equal to 0, and $f'(x)$ does not exist at $x = 0$. Because $x = 0$ is in the domain of f , 0 is a critical number of f . Evaluating f at the endpoints of the interval $[-1, 1]$ and the critical number 0 yields

$$\begin{aligned} f(-1) &= (-1)^{2/3} = 1 \\ f(0) &= 0 \\ f(1) &= 1^{2/3} = 1. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[-1, 1]$ is $\boxed{1}$ (and this occurs at both endpoints $x = \pm 1$), while the absolute minimum value of f is $\boxed{0}$ (and this occurs at the critical number $x = 0$).

44. Let $f(x) = x^{1/3}$, and consider the closed interval $[-1, 1]$. Because f is continuous on this closed interval, the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute minimum on $[-1, 1]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, the critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Moreover,

$$f'(x) = \frac{1}{3}x^{-2/3},$$

so $f'(x)$ is never equal to 0, and $f'(x)$ does not exist at $x = 0$. Because $x = 0$ is in the domain of f , 0 is a critical number of f . Evaluating f at the endpoints of the interval $[-1, 1]$ and the critical number 0 yields

$$\begin{aligned} f(-1) &= (-1)^{1/3} = -1 \\ f(0) &= 0 \\ f(1) &= 1^{1/3} = 1. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[-1, 1]$ is $\boxed{1}$ (and this occurs at the endpoint $x = 1$), while the absolute minimum value of f is $\boxed{-1}$ (and this occurs at the endpoint $x = -1$).

45. Let $f(x) = 2\sqrt{x}$, and consider the closed interval $[1, 4]$. Because f is continuous on this closed interval, the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute minimum on $[1, 4]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, the critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Moreover,

$$f'(x) = \frac{1}{\sqrt{x}},$$

so $f'(x)$ is never equal to 0, and $f'(x)$ does not exist at $x = 0$. Because $x = 0$ is in the domain of f , 0 is a critical number of f ; however, $x = 0$ is not inside the interval $(1, 4)$, so this critical number can be excluded, leaving no critical numbers inside the open interval. Evaluating f at the endpoints of the interval $[1, 4]$ yields

$$\begin{aligned} f(1) &= 2\sqrt{1} = 2 \\ f(4) &= 2\sqrt{4} = 4. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[1, 4]$ is $\boxed{4}$ (and this occurs at the endpoint $x = 4$), while the absolute minimum value of f is $\boxed{2}$ (and this occurs at the endpoint $x = 1$).

46. Let $f(x) = 4 - \sqrt{x}$, and consider the closed interval $[0, 4]$. Because f is continuous on this closed interval, the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute minimum on $[0, 4]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, the critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Moreover,

$$f'(x) = -\frac{1}{2\sqrt{x}},$$

so $f'(x)$ is never equal to 0, and $f'(x)$ does not exist at $x = 0$. Because $x = 0$ is in the domain of f , 0 is a critical number of f ; however, $x = 0$ is not inside the open interval $(0, 4)$, so this critical number can be excluded, leaving no critical numbers inside the open interval. Evaluating f at the endpoints of the interval $[0, 4]$ yields

$$\begin{aligned} f(0) &= 4 \\ f(4) &= 4 - \sqrt{4} = 2. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[0, 4]$ is $\boxed{4}$ (and this occurs at the endpoint $x = 0$), while the absolute minimum value of f is $\boxed{2}$ (and this occurs at the endpoint $x = 4$).

47. Let $f(x) = x + \sin x$, and consider the closed interval $[0, \pi]$. Because f is continuous on this closed interval, the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute minimum on $[0, \pi]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, f is differentiable everywhere, which means that the critical numbers of f occur where $f'(x) = 0$. Moreover,

$$f'(x) = 1 + \cos x = 0$$

when $\cos x = -1$. On the interval $0 \leq x \leq \pi$, $\cos x = -1$ when $x = \pi$; however, $x = \pi$ is not inside the interval $(0, \pi)$, leaving no critical numbers inside the open interval. Evaluating f at the endpoints of the interval $[0, \pi]$ yields

$$\begin{aligned} f(0) &= \sin 0 = 0 \\ f(\pi) &= \pi + \sin \pi = \pi. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[0, \pi]$ is $\boxed{\pi}$ (and this occurs at the endpoint $x = \pi$), while the absolute minimum value of f is $\boxed{0}$ (and this occurs at the endpoint $x = 0$).

48. Let $f(x) = x - \cos x$, and consider the closed interval $\left[-\frac{\pi}{2}, \frac{\pi}{2}\right]$. Because f is continuous on this closed interval, the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute minimum on $\left[-\frac{\pi}{2}, \frac{\pi}{2}\right]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, f is differentiable everywhere, which means that the critical numbers of f occur where $f'(x) = 0$. Moreover,

$$f'(x) = 1 + \sin x = 0$$

when $\sin x = -1$. On the interval $-\frac{\pi}{2} \leq x \leq \frac{\pi}{2}$, $\sin x = -1$ when $x = -\frac{\pi}{2}$; however, $x = -\frac{\pi}{2}$ is not inside the interval $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$, leaving no critical numbers inside the open interval. Evaluating f at the endpoints of the interval $\left[-\frac{\pi}{2}, \frac{\pi}{2}\right]$ yields

$$\begin{aligned} f\left(-\frac{\pi}{2}\right) &= -\frac{\pi}{2} - \cos\left(-\frac{\pi}{2}\right) = -\frac{\pi}{2} \\ f\left(\frac{\pi}{2}\right) &= \frac{\pi}{2} - \cos\left(\frac{\pi}{2}\right) = \frac{\pi}{2}. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $\left[-\frac{\pi}{2}, \frac{\pi}{2}\right]$ is $\boxed{\frac{\pi}{2}}$ (and this occurs at the endpoint $x = \frac{\pi}{2}$), while the absolute minimum value of f is $\boxed{-\frac{\pi}{2}}$ (and this occurs at the endpoint $x = -\frac{\pi}{2}$).

49. Let $f(x) = x\sqrt{1-x^2}$, and consider the closed interval $[-1, 1]$. Because f is continuous on this closed interval, the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute minimum on $[-1, 1]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, the critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Moreover,

$$\begin{aligned} f'(x) &= x \cdot \frac{1}{2}(1-x^2)^{-1/2}(-2x) + \sqrt{1-x^2} \\ &= -\frac{x^2}{\sqrt{1-x^2}} + \sqrt{1-x^2} = \frac{-x^2 + 1 - x^2}{\sqrt{1-x^2}} = \frac{1-2x^2}{\sqrt{1-x^2}}, \end{aligned}$$

so $f'(x) = 0$ when $1 - 2x^2 = 0$, or when $x = \pm \frac{\sqrt{2}}{2}$, and $f'(x)$ does not exist when $1 - x^2 = 0$, or when $x = \pm 1$. All four of these numbers are in the domain of f , so all four are critical numbers; however, of these numbers, only $x = \pm \frac{\sqrt{2}}{2}$ are inside the open interval $(-1, 1)$. Evaluating f at the endpoints of the interval $[-1, 1]$ and the critical numbers $\pm \frac{\sqrt{2}}{2}$ yields

$$\begin{aligned} f(-1) &= 0 \\ f\left(-\frac{\sqrt{2}}{2}\right) &= -\frac{\sqrt{2}}{2}\sqrt{1-\frac{1}{2}} = -\frac{1}{2} \\ f\left(\frac{\sqrt{2}}{2}\right) &= \frac{\sqrt{2}}{2}\sqrt{1-\frac{1}{2}} = \frac{1}{2} \\ f(1) &= 0. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[-1, 1]$ is $\boxed{\frac{1}{2}}$ (and this occurs at the critical number $x = \frac{\sqrt{2}}{2}$), while the absolute minimum value of f is $\boxed{-\frac{1}{2}}$ (and this occurs at the critical number $x = -\frac{\sqrt{2}}{2}$).

50. Let $f(x) = x^2\sqrt{2-x}$, and consider the closed interval $[0, 2]$. Because f is continuous on this closed interval, the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute minimum on $[0, 2]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, the critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Moreover,

$$\begin{aligned} f'(x) &= x^2 \cdot \frac{1}{2}(2-x)^{-1/2}(-1) + 2x\sqrt{2-x} \\ &= -\frac{x^2}{2\sqrt{2-x}} + 2x\sqrt{2-x} = \frac{-x^2 + 4x(2-x)}{2\sqrt{2-x}} = \frac{8x - 5x^2}{2\sqrt{2-x}}, \end{aligned}$$

so $f'(x) = 0$ when $8x - 5x^2 = x(8 - 5x) = 0$, or when $x = 0$ or $x = \frac{8}{5}$. On the other hand, $f'(x)$ does not exist when $2 - x = 0$, or when $x = 2$. All three of these numbers are in the domain of f , so all three are critical numbers; however, of these numbers, only $\frac{8}{5}$ is inside the open interval $(0, 2)$. Evaluating f at the endpoints of the interval $[0, 2]$ and the critical number $\frac{8}{5}$ yields

$$\begin{aligned} f(0) &= 0 \\ f\left(\frac{8}{5}\right) &= \frac{64}{25}\sqrt{2 - \frac{8}{5}} = \frac{64\sqrt{10}}{125} \\ f(2) &= 0. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[0, 2]$ is $\boxed{\frac{64\sqrt{10}}{125}}$ (and this occurs at the critical number $x = \frac{8}{5}$), while the absolute minimum value of f is $\boxed{0}$ (and this occurs at the endpoints $x = 0$ and $x = 2$).

51. Let $f(x) = \frac{x^2}{x-1}$, and consider the closed interval $\left[-1, \frac{1}{2}\right]$. Because f is continuous on this closed interval, the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute minimum on $\left[-1, \frac{1}{2}\right]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, the critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Moreover,

$$f'(x) = \frac{(x-1)(2x) - x^2}{(x-1)^2} = \frac{2x^2 - 2x - x^2}{(x-1)^2} = \frac{x^2 - 2x}{(x-1)^2},$$

so $f'(x) = 0$ when $x^2 - 2x = x(x - 2) = 0$, or when $x = 0$ or $x = 2$. On the other hand, $f'(x)$ does not exist when $x - 1 = 0$, or when $x = 1$. As $x = 1$ is not in the domain of f , 1 is not a critical number. Therefore, 0 and 2 are the critical numbers of f ; however, $x = 2$ is not inside the open interval $\left(-1, \frac{1}{2}\right)$, so this critical number can be excluded. Evaluating f at the endpoints of the

interval $\left[-1, \frac{1}{2}\right]$ and the critical number 0 yields

$$\begin{aligned} f(-1) &= \frac{(-1)^2}{-1-1} = -\frac{1}{2} \\ f(0) &= 0 \\ f\left(\frac{1}{2}\right) &= \frac{1/4}{-1/2} = -\frac{1}{2}. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $\left[-1, \frac{1}{2}\right]$ is $\boxed{0}$ (and this occurs at the critical number $x = 0$), while the absolute minimum value of f is $\boxed{-\frac{1}{2}}$ (and this occurs at both endpoints $x = -1$ and $x = \frac{1}{2}$).

52. Let $f(x) = \frac{x}{x^2-1}$, and consider the closed interval $\left[-\frac{1}{2}, \frac{1}{2}\right]$. Because f is continuous on this closed interval, the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute minimum on $\left[-\frac{1}{2}, \frac{1}{2}\right]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, the critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Moreover,

$$f'(x) = \frac{(x^2-1) - x(2x)}{(x^2-1)^2} = \frac{x^2-1-2x^2}{(x^2-1)^2} = -\frac{1+x^2}{(x^2-1)^2},$$

so $f'(x)$ is never equal to zero, and $f'(x)$ does not exist at $x = \pm 1$. As neither $x = 1$ nor $x = -1$ are in the domain of f , neither number is a critical number. Therefore, f has no critical numbers. Evaluating f at the endpoints of the interval $\left[-\frac{1}{2}, \frac{1}{2}\right]$ yields

$$\begin{aligned} f\left(-\frac{1}{2}\right) &= \frac{-1/2}{-3/4} = \frac{2}{3} \\ f\left(\frac{1}{2}\right) &= \frac{1/2}{-3/4} = -\frac{2}{3}. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $\left[-\frac{1}{2}, \frac{1}{2}\right]$ is $\boxed{\frac{2}{3}}$ (and this occurs at the endpoint $x = -\frac{1}{2}$), while the absolute minimum value of f is $\boxed{-\frac{2}{3}}$ (and this occurs at the endpoint $x = \frac{1}{2}$).

53. Let $f(x) = (x+3)^2(x-1)^{2/3}$, and consider the closed interval $[-4, 5]$. Because f is continuous on this closed interval, the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute minimum on $[-4, 5]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, the critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Moreover,

$$\begin{aligned} f'(x) &= (x+3)^2 \cdot \frac{2}{3}(x-1)^{-1/3} + (x-1)^{2/3} \cdot 2(x+3) \\ &= \frac{2(x+3)^2}{3(x-1)^{1/3}} + 2(x+3)(x-1)^{2/3} = \frac{2(x+3)^2 + 6(x+3)(x-1)}{3(x-1)^{1/3}} \\ &= \frac{2(x+3)[x+3+3(x-1)]}{3(x-1)^{1/3}} = \frac{8x(x+3)}{3(x-1)^{1/3}}, \end{aligned}$$

so $f'(x) = 0$ when $8x(x+3) = 0$, or when $x = 0$ or $x = -3$. On the other hand, $f'(x)$ does not exist when $x - 1 = 0$, or when $x = 1$. All three of these numbers are in the domain of f , so all three are critical numbers. Evaluating f at the endpoints of the interval $[-4, 5]$ and the critical numbers -3 , 0 , and 1 yields

$$\begin{aligned} f(-4) &= (-1)^2(-5)^{2/3} = 25^{1/3} = \sqrt[3]{25} \approx 2.924 \\ f(-3) &= 0 \\ f(0) &= 3^2(-1)^{2/3} = 9 \\ f(1) &= 0 \\ f(5) &= 8^2(4)^{2/3} = 64(4)^{2/3} = 64\sqrt[3]{16} \approx 161.270. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[-4, 5]$ is $\boxed{64\sqrt[3]{16}}$ (and this occurs at the endpoint $x = 5$), while the absolute minimum value of f is $\boxed{0}$ (and this occurs at the critical numbers $x = -3$ and $x = 1$).

54. Let $f(x) = (x-1)^2(x+1)^{1/3}$, and consider the closed interval $[-2, 7]$. Because f is continuous on this closed interval, the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute minimum on $[-2, 7]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, the critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Moreover,

$$\begin{aligned} f'(x) &= (x-1)^2 \cdot \frac{1}{3}(x+1)^{-2/3} + (x+1)^{1/3} \cdot 2(x-1) \\ &= \frac{(x-1)^2}{3(x+1)^{2/3}} + 2(x-1)(x+1)^{1/3} = \frac{(x-1)^2 + 6(x-1)(x+1)}{3(x+1)^{2/3}} \\ &= \frac{(x-1)[x-1+6(x+1)]}{3(x+1)^{2/3}} = \frac{(x-1)(7x+5)}{3(x+1)^{2/3}}, \end{aligned}$$

so $f'(x) = 0$ when $(x-1)(7x+5) = 0$, or when $x = 1$ or $x = -\frac{5}{7}$. On the other hand, $f'(x)$ does not exist when $x+1 = 0$, or when $x = -1$. All three of these numbers are in the domain of f , so all three are critical numbers. Evaluating f at the endpoints of the interval $[-2, 7]$ and the critical numbers -1 , $-\frac{5}{7}$, and 1 yields

$$\begin{aligned} f(-2) &= (-3)^2(-1)^{1/3} = -9 \\ f(-1) &= 0 \\ f\left(-\frac{5}{7}\right) &= \left(-\frac{12}{7}\right)^2 \left(\frac{2}{7}\right)^{1/3} \approx 1.936 \\ f(1) &= 0 \\ f(7) &= 6^2(8)^{1/3} = 72. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[-2, 7]$ is $\boxed{72}$ (and this occurs at the endpoint $x = 7$), while the absolute minimum value of f is $\boxed{-9}$ (and this occurs at the endpoint $x = -2$).

55. Let $f(x) = \frac{(x-3)^{1/3}}{x-1}$, and consider the closed interval $[2, 11]$. Because f is continuous on this closed interval, the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute minimum on $[2, 11]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, the critical numbers of f occur

where $f'(x) = 0$ or where $f'(x)$ does not exist. Moreover,

$$\begin{aligned} f'(x) &= \frac{(x-1) \cdot \frac{1}{3}(x-3)^{-2/3} - (x-3)^{1/3}}{(x-1)^2} \cdot \frac{3(x-3)^{2/3}}{3(x-3)^{2/3}} \\ &= \frac{(x-1) - 3(x-3)}{3(x-1)^2(x-3)^{2/3}} = \frac{8-2x}{3(x-1)^2(x-3)^{2/3}}, \end{aligned}$$

so $f'(x) = 0$ when $8 - 2x = 0$, or when $x = 4$. On the other hand, $f'(x)$ does not exist when $(x-1)^2(x-3)^{2/3} = 0$, or when $x = 1$ or $x = 3$. As $x = 1$ is not in the domain of f , 1 is not a critical number. Therefore, 3 and 4 are critical numbers of f . Evaluating f at the endpoints of the interval $[2, 11]$ and the critical numbers 3 and 4 yields

$$\begin{aligned} f(2) &= \frac{(-1)^{1/3}}{1} = -1 \\ f(3) &= 0 \\ f(4) &= \frac{1^{1/3}}{3} = \frac{1}{3} \\ f(11) &= \frac{8^{1/3}}{10} = \frac{1}{5}. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[2, 11]$ is $\boxed{\frac{1}{3}}$ (and this occurs at the critical number $x = 4$), while the absolute minimum value of f is $\boxed{-1}$ (and this occurs at the endpoint $x = 2$).

56. Let $f(x) = \frac{(x+3)^{2/3}}{x+1}$, and consider the closed interval $[-4, -2]$. Because f is continuous on this closed interval, the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute minimum on $[-4, -2]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, the critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Moreover,

$$\begin{aligned} f'(x) &= \frac{(x+1) \cdot \frac{2}{3}(x+3)^{-1/3} - (x+3)^{2/3}}{(x+1)^2} \cdot \frac{3(x+3)^{1/3}}{3(x+3)^{1/3}} \\ &= \frac{2(x+1) - 3(x+3)}{3(x+1)^2(x+3)^{1/3}} = -\frac{x+7}{3(x+1)^2(x+3)^{1/3}}, \end{aligned}$$

so $f'(x) = 0$ when $x + 7 = 0$, or when $x = -7$. On the other hand, $f'(x)$ does not exist when $(x+1)^2(x+3)^{1/3} = 0$, or when $x = -1$ or $x = -3$. As $x = -1$ is not in the domain of f , -1 is not a critical number. Therefore, -7 and -3 are critical numbers of f ; however, $x = -7$ is not inside the interval $(-4, -2)$, so this critical number can be excluded. Evaluating f at the endpoints of the interval $[-4, -2]$ and the critical number -3 yields

$$\begin{aligned} f(-4) &= \frac{(-1)^{2/3}}{-3} = -\frac{1}{3} \\ f(-3) &= 0 \\ f(-2) &= \frac{1^{2/3}}{-1} = -1. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[-4, -2]$ is $\boxed{0}$ (and this occurs at the critical number $x = -3$), while the absolute minimum value of f is $\boxed{-1}$ (and this occurs at the endpoint $x = -2$).

57. Let $f(x) = \frac{\sqrt[3]{x^2-9}}{x}$, and consider the closed interval $[3, 6]$. Because f is continuous on this closed interval, the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute

minimum on $[3, 6]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, the critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Moreover,

$$\begin{aligned} f'(x) &= \frac{x \cdot \frac{1}{3}(x^2 - 9)^{-2/3}(2x) - \sqrt[3]{x^2 - 9}}{x^2} \cdot \frac{3(x^2 - 9)^{2/3}}{3(x^2 - 9)^{2/3}} \\ &= \frac{2x^2 - 3(x^2 - 9)}{3x^2(x^2 - 9)^{2/3}} = \frac{27 - x^2}{3x^2(x^2 - 9)^{2/3}}, \end{aligned}$$

so $f'(x) = 0$ when $27 - x^2 = 0$, or when $x = \pm\sqrt{27} = \pm 3\sqrt{3}$. On the other hand, $f'(x)$ does not exist when $x^2(x^2 - 9)^{2/3} = 0$, or when $x = 0$ or $x = \pm 3$. As $x = 0$ is not in the domain of f , 0 is not a critical number. Therefore, ± 3 and $\pm 3\sqrt{3}$ are critical numbers of f ; however, of these numbers, only $3\sqrt{3}$ is inside the open interval $(3, 6)$. Evaluating f at the endpoints of the interval $[3, 6]$ and the critical number $3\sqrt{3}$ yields

$$\begin{aligned} f(3) &= 0 \\ f(3\sqrt{3}) &= \frac{\sqrt[3]{18}}{3\sqrt{3}} \approx 0.504 \\ f(6) &= \frac{\sqrt[3]{27}}{6} = \frac{1}{2}. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[3, 6]$ is $\boxed{\frac{\sqrt[3]{18}}{3\sqrt{3}}}$ (and this occurs at the critical number $x = 3\sqrt{3}$), while the absolute minimum value of f is $\boxed{0}$ (and this occurs at the endpoint $x = 3$).

58. Let $f(x) = \frac{\sqrt[3]{4 - x^2}}{x}$, and consider the closed interval $[-4, -1]$. Because f is continuous on this closed interval, the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute minimum on $[-4, -1]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, the critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Moreover,

$$\begin{aligned} f'(x) &= \frac{x \cdot \frac{1}{3}(4 - x^2)^{-2/3}(-2x) - \sqrt[3]{4 - x^2}}{x^2} \cdot \frac{3(4 - x^2)^{2/3}}{3(4 - x^2)^{2/3}} \\ &= \frac{-2x^2 - 3(4 - x^2)}{3x^2(4 - x^2)^{2/3}} = \frac{x^2 - 12}{3x^2(4 - x^2)^{2/3}}, \end{aligned}$$

so $f'(x) = 0$ when $x^2 - 12 = 0$, or when $x = \pm\sqrt{12} = \pm 2\sqrt{3}$. On the other hand, $f'(x)$ does not exist when $x^2(4 - x^2)^{2/3} = 0$, or when $x = 0$ or $x = \pm 2$. As $x = 0$ is not in the domain of f , 0 is not a critical number. Therefore, ± 2 and $\pm 2\sqrt{3}$ are critical numbers of f ; however, $x = 2$ and $x = 2\sqrt{3}$ are not inside the interval $(-4, -1)$, so these critical numbers can be excluded. Evaluating f at the endpoints of the interval $[-4, -1]$ and the critical numbers $-2\sqrt{3}$ and -2 yields

$$\begin{aligned} f(-4) &= \frac{\sqrt[3]{-12}}{-4} = \frac{\sqrt[3]{12}}{4} \approx 0.572 \\ f(-2\sqrt{3}) &= \frac{\sqrt[3]{-8}}{-2\sqrt{3}} = \frac{\sqrt{3}}{3} \approx 0.577 \\ f(-2) &= 0 \\ f(-1) &= \frac{\sqrt[3]{3}}{-1} = -\sqrt[3]{3}. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[-4, -1]$ is $\boxed{\frac{\sqrt{3}}{3}}$ (and this occurs at the critical number $x = -2\sqrt{3}$), while the absolute minimum value of f is $\boxed{-\frac{\sqrt{3}}{3}}$ (and this occurs at the endpoint $x = -1$).

59. Let $f(x) = e^x - 3x$, and consider the closed interval $[0, 1]$. Because f is continuous on this closed interval, the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute minimum on $[0, 1]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, f is differentiable everywhere, which means that the critical numbers of f occur where $f'(x) = 0$. Moreover,

$$f'(x) = e^x - 3 = 0$$

when $x = \ln 3$. Therefore, $\ln 3$ is the only critical number of f ; however, $x = \ln 3 \approx 1.099$ is not inside the interval $(0, 1)$, so this critical number can be excluded, leaving no critical numbers inside the open interval. Evaluating f at the endpoints of the interval $[0, 1]$ yields

$$\begin{aligned} f(0) &= e^0 - 3(0) = 1 \\ f(1) &= e^1 - 3(1) = e - 3 \approx -0.282. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[0, 1]$ is $\boxed{1}$ (and this occurs at the endpoint $x = 0$), while the absolute minimum value of f is $\boxed{e - 3}$ (and this occurs at the endpoint $x = 1$).

60. Let $f(x) = e^{\cos x}$, and consider the closed interval $[-\pi, 2\pi]$. Because f is continuous on this closed interval, the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute minimum on $[-\pi, 2\pi]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, f is differentiable everywhere, which means that the critical numbers of f occur where $f'(x) = 0$. Moreover,

$$f'(x) = -\sin x e^{\cos x} = 0$$

when $\sin x = 0$. On the interval $-\pi \leq x \leq 2\pi$, $\sin x = 0$ when $x = -\pi$, $x = 0$, $x = \pi$, and $x = 2\pi$; however, $-\pi$ and 2π are not inside the interval $(-\pi, 2\pi)$, so these critical numbers can be excluded, leaving only 0 and π inside the open interval. Evaluating f at the endpoints of the interval $[-\pi, 2\pi]$ and the critical numbers 0 and π yields

$$\begin{aligned} f(-\pi) &= e^{\cos(-\pi)} = e^{-1} \\ f(0) &= e^{\cos 0} = e \\ f(\pi) &= e^{\cos \pi} = e^{-1} \\ f(2\pi) &= e^{\cos(2\pi)} = e. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[-\pi, 2\pi]$ is $\boxed{e}$ (and this occurs at the critical number $x = 0$ and at the endpoint $x = 2\pi$), while the absolute minimum value of f is $\boxed{e^{-1}}$ (and this occurs at the endpoint $x = -\pi$ and at the critical number $x = \pi$).

61. The function f is continuous on the intervals $[0, 1)$ and $(1, 3]$ because the component functions $2x + 1$ and $3x$ are continuous on these intervals, respectively. At $x = 1$,

$$\lim_{x \rightarrow 1^-} f(x) = \lim_{x \rightarrow 1^-} (2x + 1) = 3 \quad \text{and} \quad \lim_{x \rightarrow 1^+} f(x) = \lim_{x \rightarrow 1^+} (3x) = 3,$$

so that $\lim_{x \rightarrow 1} f(x)$ exists and is equal to 3. As $f(1) = 3(1) = 3$, it follows that f is continuous at $x = 1$. Hence, f is continuous on the closed interval $[0, 3]$.

Now, on the interval $[0, 1)$, $f(x) = 2x + 1$ so $f'(x) = 2$. Because $f'(x)$ exists everywhere on the interval $[0, 1)$ and is never equal to 0, f has no critical numbers in $[0, 1)$. On the interval $(1, 3]$, $f(x) = 3x$,

so $f'(x) = 3$. Because $f'(x)$ exists everywhere on the interval $(1, 3]$ and is never equal to 0, f has no critical numbers in $(1, 3]$. At $x = 1$, the rule for f changes, so it is necessary to investigate the existence of $f'(1)$. Now,

$$\lim_{x \rightarrow 1^-} \frac{f(x) - f(1)}{x - 1} = \lim_{x \rightarrow 1^-} \frac{(2x + 1) - 3}{x - 1} = \lim_{x \rightarrow 1^-} \frac{2(x - 1)}{x - 1} = \lim_{x \rightarrow 1^-} 2 = 2,$$

and

$$\lim_{x \rightarrow 1^+} \frac{f(x) - f(1)}{x - 1} = \lim_{x \rightarrow 1^+} \frac{3x - 3}{x - 1} = \lim_{x \rightarrow 1^+} \frac{3(x - 1)}{x - 1} = \lim_{x \rightarrow 1^+} 3 = 3.$$

Because these two one-sided limits are not equal, $f'(x)$ does not exist at $x = 1$. Therefore, 1 is the only critical number of f . Evaluating f at the endpoints of the interval $[0, 3]$ and the critical number 1 yields

$$\begin{aligned} f(0) &= 2(0) + 1 = 1 \\ f(1) &= 3(1) = 3 \\ f(3) &= 3(3) = 9. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[0, 3]$ is $\boxed{9}$ (and this occurs at the endpoint $x = 3$), while the absolute minimum value of f is $\boxed{1}$ (and this occurs at the endpoint $x = 0$).

62. The function f is continuous on the intervals $[-1, 2)$ and $(2, 4]$ because the component functions $x + 3$ and $2x + 1$ are continuous on these intervals, respectively. At $x = 2$,

$$\lim_{x \rightarrow 2^-} f(x) = \lim_{x \rightarrow 2^-} (x + 3) = 5 \quad \text{and} \quad \lim_{x \rightarrow 2^+} f(x) = \lim_{x \rightarrow 2^+} (2x + 1) = 5,$$

so that $\lim_{x \rightarrow 2} f(x)$ exists and is equal to 5. As $f(2) = 2 + 3 = 5$, it follows that f is continuous at $x = 2$. Hence, f is continuous on the closed interval $[-1, 4]$.

Now, on the interval $[-1, 2)$, $f(x) = x + 3$ so $f'(x) = 1$. Because $f'(x)$ exists everywhere on the interval $[-1, 2)$ and is never equal to 0, f has no critical numbers in $[-1, 2)$. On the interval $(2, 4]$, $f(x) = 2x + 1$, so $f'(x) = 2$. Because $f'(x)$ exists everywhere on the interval $(2, 4]$ and is never equal to 0, f has no critical numbers in $(2, 4]$. At $x = 2$, the rule for f changes, so it is necessary to investigate the existence of $f'(2)$. Now,

$$\lim_{x \rightarrow 2^-} \frac{f(x) - f(2)}{x - 2} = \lim_{x \rightarrow 2^-} \frac{(x + 3) - 5}{x - 2} = \lim_{x \rightarrow 2^-} \frac{x - 2}{x - 2} = \lim_{x \rightarrow 2^-} 1 = 1,$$

and

$$\lim_{x \rightarrow 2^+} \frac{f(x) - f(2)}{x - 2} = \lim_{x \rightarrow 2^+} \frac{(2x + 1) - 5}{x - 2} = \lim_{x \rightarrow 2^+} \frac{2(x - 2)}{x - 2} = \lim_{x \rightarrow 2^+} 2 = 2.$$

Because these two one-sided limits are not equal, $f'(x)$ does not exist at $x = 2$. Therefore, 2 is the only critical number of f . Evaluating f at the endpoints of the interval $[-1, 4]$ and the critical number 2 yields

$$\begin{aligned} f(-1) &= -1 + 3 = 2 \\ f(2) &= 2 + 3 = 5 \\ f(4) &= 2(4) + 1 = 9. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[-1, 4]$ is $\boxed{9}$ (and this occurs at the endpoint $x = 4$), while the absolute minimum value of f is $\boxed{2}$ (and this occurs at the endpoint $x = -1$).

63. The function f is continuous on the intervals $[-2, 1)$ and $(1, 2]$ because the component functions x^2 and x^3 are continuous on these intervals, respectively. At $x = 1$,

$$\lim_{x \rightarrow 1^-} f(x) = \lim_{x \rightarrow 1^-} x^2 = 1 \quad \text{and} \quad \lim_{x \rightarrow 1^+} f(x) = \lim_{x \rightarrow 1^+} x^3 = 1,$$

so that $\lim_{x \rightarrow 1} f(x)$ exists and is equal to 1. As $f(1) = 1^3 = 1$, it follows that f is continuous at $x = 1$. Hence, f is continuous on the closed interval $[-2, 2]$.

Now, on the interval $[-2, 1)$, $f(x) = x^2$ so $f'(x) = 2x$. Because $f'(x)$ exists everywhere on the interval $[-2, 1)$ but is equal to 0 at $x = 0$, 0 is a critical number in $[-2, 1)$. On the interval $(1, 2]$, $f(x) = x^3$, so $f'(x) = 3x^2$. Because $f'(x)$ exists everywhere and is never equal to 0 on the interval $(1, 2]$, f has no critical numbers in $(1, 2]$. At $x = 1$, the rule for f changes, so it is necessary to investigate the existence of $f'(1)$. Now,

$$\lim_{x \rightarrow 1^-} \frac{f(x) - f(1)}{x - 1} = \lim_{x \rightarrow 1^-} \frac{x^2 - 1}{x - 1} = \lim_{x \rightarrow 1^-} \frac{(x + 1)(x - 1)}{x - 1} = \lim_{x \rightarrow 1^-} (x + 1) = 2,$$

and

$$\lim_{x \rightarrow 1^+} \frac{f(x) - f(1)}{x - 1} = \lim_{x \rightarrow 1^+} \frac{x^3 - 1}{x - 1} = \lim_{x \rightarrow 1^+} \frac{(x - 1)(x^2 + x + 1)}{x - 1} = \lim_{x \rightarrow 1^+} (x^2 + x + 1) = 3.$$

Because these two one-sided limits are not equal, $f'(x)$ does not exist at $x = 1$. Therefore, 1 is a critical number of f . Evaluating f at the endpoints of the interval $[-2, 2]$ and the critical numbers 0 and 1 yields

$$\begin{aligned} f(-2) &= (-2)^2 = 4 \\ f(0) &= 0^2 = 0 \\ f(1) &= 1^3 = 1 \\ f(2) &= 2^3 = 8. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[-2, 2]$ is $\boxed{8}$ (and this occurs at the endpoint $x = 2$), while the absolute minimum value of f is $\boxed{0}$ (and this occurs at the critical number $x = 0$).

64. The function f is continuous on the intervals $[-1, 0)$ and $(0, 1]$ because the component functions $x + 2$ and $2 - x$ are continuous on these intervals, respectively. At $x = 0$,

$$\lim_{x \rightarrow 0^-} f(x) = \lim_{x \rightarrow 0^-} (x + 2) = 2 \quad \text{and} \quad \lim_{x \rightarrow 0^+} f(x) = \lim_{x \rightarrow 0^+} (2 - x) = 2,$$

so that $\lim_{x \rightarrow 0} f(x)$ exists and is equal to 2. As $f(0) = 2 - 0 = 2$, it follows that f is continuous at $x = 2$. Hence, f is continuous on the closed interval $[-1, 1]$.

Now, on the interval $[-1, 0)$, $f(x) = x + 2$ so $f'(x) = 1$. Because $f'(x)$ exists everywhere on the interval $[-1, 0)$ and is never equal to 0, f has no critical numbers in $[-1, 0)$. On the interval $(0, 1]$, $f(x) = 2 - x$, so $f'(x) = -1$. Because $f'(x)$ exists everywhere on the interval $(0, 1]$ and is never equal to 0, f has no critical numbers in $(0, 1]$. At $x = 0$, the rule for f changes, so it is necessary to investigate the existence of $f'(0)$. Now,

$$\lim_{x \rightarrow 0^-} \frac{f(x) - f(0)}{x - 0} = \lim_{x \rightarrow 0^-} \frac{(x + 2) - 2}{x} = \lim_{x \rightarrow 0^-} \frac{x}{x} = \lim_{x \rightarrow 0^-} 1 = 1,$$

and

$$\lim_{x \rightarrow 0^+} \frac{f(x) - f(0)}{x - 0} = \lim_{x \rightarrow 0^+} \frac{(2 - x) - 2}{x} = \lim_{x \rightarrow 0^+} \frac{-x}{x} = \lim_{x \rightarrow 0^+} -1 = -1.$$

Because these two one-sided limits are not equal, $f'(x)$ does not exist at $x = 0$. Therefore, 0 is the only critical number of f . Evaluating f at the endpoints of the interval $[-1, 1]$ and the critical number 0 yields

$$\begin{aligned} f(-1) &= -1 + 2 = 1 \\ f(0) &= 2 - 0 = 2 \\ f(1) &= 2 - 1 = 1. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[-1, 1]$ is $\boxed{2}$ (and this occurs at the critical number $x = 0$), while the absolute minimum value of f is $\boxed{1}$ (and this occurs at both endpoints $x = \pm 1$).

Applications and Extensions

65. Let $f(x) = 3x^4 - 2x^3 - 21x^2 + 36x$.

(a) Then $\boxed{f'(x) = 12x^3 - 6x^2 - 42x + 36}$.

(b) The polynomial function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Using the computer algebra system *Maple*,

$$12x^3 - 6x^2 - 42x + 36 = 0$$

when $x = -2$, $x = 1$, and $x = \frac{3}{2}$. Therefore, $\boxed{-2, 1, \text{ and } \frac{3}{2}}$ are the critical numbers of f .

(c) The figure below displays the graph of f . The graph suggests that f has an $\boxed{\text{absolute minimum at } -2}$, a $\boxed{\text{local maximum at } 1}$, and a $\boxed{\text{local minimum at } \frac{3}{2}}$.

66. Let $f(x) = x^2 + 2x - \frac{2}{x}$.

(a) Then $\boxed{f'(x) = 2x + 2 + \frac{2}{x^2}}$.

(b) The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now, $f'(x)$ does not exist at $x = 0$; however, $x = 0$ is not in the domain of f , so 0 is not a critical number. Using the computer algebra system *Maple*,

$$2x + 2 + \frac{2}{x^2} = 0$$

when $x \approx -1.466$. Therefore, $\boxed{-1.466}$ is the only critical number of f .

(c) The figure below displays the graph of f . The graph suggests that f has a $\boxed{\text{local minimum at } -1.466}$.

67. Let $f(x) = \frac{(x^2 - 5x + 2)\sqrt{x + 5}}{\sqrt{x^2 + 2}}$.

(a) Then

$$\ln f(x) = \ln \left(\frac{(x^2 - 5x + 2)\sqrt{x + 5}}{\sqrt{x^2 + 2}} \right) = \ln(x^2 - 5x + 2) + \frac{1}{2} \ln(x + 5) - \frac{1}{2} \ln(x^2 + 2)$$

and

$$\begin{aligned} \frac{d}{dx} \ln f(x) &= \frac{d}{dx} \left(\ln(x^2 - 5x + 2) + \frac{1}{2} \ln(x + 5) - \frac{1}{2} \ln(x^2 + 2) \right) \\ \frac{1}{f(x)} \frac{df}{dx} &= \frac{1}{x^2 - 5x + 2} \cdot (2x - 5) + \frac{1}{2} \cdot \frac{1}{x + 5} - \frac{1}{2} \cdot \frac{1}{x^2 + 2} \cdot 2x \\ &= \frac{2x - 5}{x^2 - 5x + 2} + \frac{1}{2x + 10} - \frac{x}{x^2 + 2} \\ &= \frac{(2x - 5)(2x + 10)(x^2 + 2) + (x^2 - 5x + 2)(x^2 + 2) - x(x^2 - 5x + 2)(2x + 10)}{2(x^2 - 5x + 2)(x + 5)(x^2 + 2)} \\ &= \frac{(4x^4 + 10x^3 - 42x^2 + 20x - 100) + (x^4 - 5x^3 + 4x^2 - 10x + 4) - (2x^4 - 46x^2 + 20x)}{2(x^2 - 5x + 2)(x + 5)(x^2 + 2)} \\ &= \frac{3x^4 + 5x^3 + 8x^2 - 10x - 96}{2(x^2 - 5x + 2)(x + 5)(x^2 + 2)}. \end{aligned}$$

Therefore,

$$f'(x) = \frac{(x^2 - 5x + 2)\sqrt{x + 5}}{\sqrt{x^2 + 2}} \cdot \frac{3x^4 + 5x^3 + 8x^2 - 10x - 96}{2(x^2 - 5x + 2)(x + 5)(x^2 + 2)} = \boxed{\frac{3x^4 + 5x^3 + 8x^2 - 10x - 96}{2\sqrt{x + 5}(x^2 + 2)^{3/2}}}.$$

- (b) The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now, $f'(x)$ does not exist at $x = -5$. Using the computer algebra system *Maple*,

$$\frac{3x^4 + 5x^3 + 8x^2 - 10x - 96}{2\sqrt{x + 5}(x^2 + 2)^{3/2}} = 0$$

when $x \approx -2.364$ and $x \approx 1.977$. Therefore, $\boxed{-5, -2.364, \text{ and } 1.977}$ are the critical numbers of f .

- (c) The figure below displays the graph of f . The graph suggests that f has an $\boxed{\text{absolute minimum at } 1.977}$, a $\boxed{\text{local maximum at } -2.364}$, and

$\boxed{\text{neither a local maximum nor a local minimum at } -5}$.

68. Let $f(x) = \frac{(x^2 - 9x + 16)\sqrt{x+3}}{\sqrt{x^2 - 4x + 6}}$.

(a) Then

$$\ln f(x) = \ln \left(\frac{(x^2 - 9x + 16)\sqrt{x+3}}{\sqrt{x^2 - 4x + 6}} \right) = \ln(x^2 - 9x + 16) + \frac{1}{2} \ln(x+3) - \frac{1}{2} \ln(x^2 - 4x + 6)$$

and

$$\begin{aligned} \frac{d}{dx} \ln f(x) &= \frac{d}{dx} \left(\ln(x^2 - 9x + 16) + \frac{1}{2} \ln(x+3) - \frac{1}{2} \ln(x^2 - 4x + 6) \right) \\ \frac{1}{f(x)} \frac{df}{dx} &= \frac{1}{x^2 - 9x + 16} \cdot (2x - 9) + \frac{1}{2} \cdot \frac{1}{x+3} - \frac{1}{2} \cdot \frac{1}{x^2 - 4x + 6} \cdot (2x - 4) \\ &= \frac{2x - 9}{x^2 - 9x + 16} + \frac{1}{2x + 6} - \frac{x - 2}{x^2 - 4x + 6} \\ &= \frac{(2x - 9)(2x + 6)(x^2 - 4x + 6) + (x^2 - 9x + 16)(x^2 - 4x + 6) - (x - 2)(x^2 - 9x + 16)(2x + 6)}{2(x^2 - 9x + 16)(x + 3)(x^2 - 4x + 6)} \\ &= \frac{3x^4 - 19x^3 + 50x^2 - 78x - 36}{2(x^2 - 9x + 16)(x + 3)(x^2 - 4x + 6)}. \end{aligned}$$

Therefore,

$$f'(x) = \frac{(x^2 - 9x + 16)\sqrt{x+3}}{\sqrt{x^2 - 4x + 6}} \cdot \frac{3x^4 - 19x^3 + 50x^2 - 78x - 36}{2(x^2 - 9x + 16)(x + 3)(x^2 - 4x + 6)} = \boxed{\frac{3x^4 - 19x^3 + 50x^2 - 78x - 36}{2\sqrt{x+3}(x^2 - 4x + 6)^{3/2}}}.$$

(b) The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now, $f'(x)$ does not exist at $x = -3$. Using the computer algebra system *Maple*,

$$\frac{3x^4 - 19x^3 + 50x^2 - 78x - 36}{2\sqrt{x+3}(x^2 - 4x + 6)^{3/2}} = 0$$

when $x \approx -0.364$ and $x \approx 3.977$. Therefore, $\boxed{-3, -0.364, \text{ and } 3.977}$ are the critical numbers of f .

(c) The figure below displays the graph of f . The graph suggests that f has a $\boxed{\text{local minimum at } 3.977}$, a $\boxed{\text{local maximum at } -0.364}$, and $\boxed{\text{neither a local maximum nor a local minimum at } -3}$.

69. Let $f(x) = x^4 - 12.4x^3 + 49.24x^2 - 68.64x$.

(a) Then $f'(x) = 4x^3 - 37.2x^2 + 98.48x - 68.64$.

(b) Consider the closed interval $[0, 5]$. Because f is continuous on this closed interval, the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute minimum on $[0, 5]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, f is a polynomial function, so it is differentiable everywhere, which means that the critical numbers of f occur where $f'(x) = 0$. Using the computer algebra system *Maple*,

$$4x^3 - 37.2x^2 + 98.48x - 68.64 = 0$$

when $x = 1.1$, when $x = 3$, and when $x = 5.2$. Therefore, 1.1, 3, and 5.2 are the critical numbers of f ; however, $x = 5.2$ is not inside the open interval $(0, 5)$, so this critical number can be excluded. Evaluating f at the endpoints of the interval $[0, 5]$ and at the critical numbers 1.1 and 3 yields

$$\begin{aligned} f(0) &= 0 \\ f(1.1) &= -30.9639 \\ f(3) &= -16.56 \\ f(5) &= -37.2. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[0, 5]$ is 0 (and this occurs at the endpoint $x = 0$), while the absolute minimum value of f is -37.2 (and this occurs at the endpoint $x = 5$).

(c) The figure below displays the graph of f , which does support the conclusions from part (b): the absolute maximum occurs at 0 and the absolute minimum occurs at 5.

70. Let $f(x) = e^{-x} \sin(2x) + e^{-x/2} \cos(2x)$.

(a) Then

$$\begin{aligned} f'(x) &= e^{-x} \cdot 2 \cos(2x) - e^{-x} \sin(2x) - e^{-x/2} \cdot 2 \sin(2x) - \frac{1}{2} e^{-x/2} \cos(2x) \\ &= \left(2e^{-x} - \frac{1}{2} e^{-x/2} \right) \cos(2x) - \left(e^{-x} + 2e^{-x/2} \right) \sin(2x). \end{aligned}$$

(b) Consider the closed interval $[0, 5]$. Because f is continuous on this closed interval, the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute minimum on $[0, 5]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, f is differentiable everywhere, which means that the critical numbers of f occur where $f'(x) = 0$. Using the computer algebra system *Maple*,

$$\left(2e^{-x} - \frac{1}{2} e^{-x/2} \right) \cos(2x) - \left(e^{-x} + 2e^{-x/2} \right) \sin(2x) = 0$$

on the open interval $(0, 5)$ when $x \approx 0.211$, when $x \approx 1.648$, when $x \approx 3.123$ and when $x \approx 4.641$. Therefore, 0.211, 1.648, 3.123, and 4.641 are the critical numbers of f . Evaluating f at the endpoints of the interval $[0, 5]$ and at the critical numbers 0.211, 1.648, 3.123, and 4.641 yields

$$\begin{aligned} f(0) &= 1 \\ f(0.211) &\approx 1.153 \\ f(1.648) &\approx -0.463 \\ f(3.123) &\approx 0.208 \\ f(4.641) &\approx -0.096 \\ f(5) &\approx -0.073. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[0, 5]$ is approximately 1.153 (and this occurs at the critical number $x \approx 0.211$), while the absolute minimum value of f is approximately -0.463 (and this occurs at the critical number $x \approx 1.648$).

(c) The figure below displays the graph of f , which does support the conclusions from part (b): the absolute maximum occurs at approximately 0.211 and the absolute minimum occurs at approximately 1.648.

71. (a) Let $C(x) = 3.60 \left(\frac{2500}{x} + x \right)$ and consider the interval $[10, 75]$. Because C is continuous on this closed interval, the Extreme Value Theorem guarantees that C has an absolute maximum and an absolute minimum on $[10, 75]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. The critical numbers of C occur where $C'(x) = 0$ or where $C'(x)$ does not exist. Now,

$$C'(x) = 3.60 \left(-\frac{2500}{x^2} + 1 \right),$$

so $C'(x) = 0$ when $x = \pm 50$ and $C'(x)$ does not exist when $x = 0$. Because $x = 0$ is not in the domain of C , 0 is not a critical number. Therefore, ± 50 are the critical numbers of C ; however, $x = -50$ is not inside the open interval $(10, 75)$, so this number can be excluded. Evaluating C at the endpoints of the interval $[10, 75]$ and at the critical number 50 yields

$$C(10) = 3.60 \left(\frac{2500}{10} + 10 \right) = 3.60(260) = 936$$

$$C(50) = 3.60 \left(\frac{2500}{50} + 50 \right) = 3.60(100) = 360$$

$$C(75) = 3.60 \left(\frac{2500}{75} + 75 \right) = 3.60 \cdot \frac{325}{3} = 390.$$

Therefore, the absolute minimum value of C on the interval $[10, 75]$ is \$360 and this occurs at $x = 50$. The most economical speed for the truck to travel is 50 miles per hour.

- (b) The figure below displays the graph of C .

72. Working from the set-up of the previous problem, the time it takes to drive 200 miles at the rate of x miles per hour is $\frac{200}{x}$ hours. If the driver is paid \$28.00 per hour, then the total cost of the trip is

$$C(x) = 3.60 \left(\frac{2500}{x} + x \right) + 28 \cdot \frac{200}{x} = \frac{14600}{x} + 3.60x.$$

The critical numbers of C occur where $C'(x) = 0$ or where $C'(x)$ does not exist. Now,

$$C'(x) = -\frac{14600}{x^2} + 3.6,$$

so $C'(x) = 0$ when $x \approx \pm 63.68$ and $C'(x)$ does not exist when $x = 0$. Because $x = 0$ is not in the domain of C , 0 is not a critical number. Therefore, ± 63.68 are the critical numbers of C ; however, $x = -63.68$ is not inside the interval $(10, 75)$, so this number can be excluded. Evaluating C at the endpoints of the interval $[10, 75]$ and at the critical number 63.68 yields

$$\begin{aligned} C(10) &= \frac{14600}{10} + 3.60(10) = 1496 \\ C(63.68) &= \frac{14600}{63.68} + 3.60(63.68) \approx 458.52 \\ C(75) &= \frac{14600}{75} + 3.60(75) \approx 464.67. \end{aligned}$$

Therefore, the absolute minimum value of C on the interval $[10, 75]$ is approximately \$458.52 and this occurs at $x \approx 63.68$. The most economical speed for the truck to travel is approximately 63.68 miles per hour.

73. Let $R(\theta) = \frac{v_0^2 \sqrt{2}}{16} \cos \theta (\sin \theta - \cos \theta)$.

- (a) Consider the closed interval $[45^\circ, 90^\circ]$. Because R is continuous on this closed interval, the Extreme Value Theorem guarantees that R has an absolute maximum and an absolute minimum on $[45^\circ, 90^\circ]$. The absolute maximum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, R is differentiable everywhere, which means that the critical numbers of R occur where $R'(\theta) = 0$. Moreover,

$$\begin{aligned} R'(\theta) &= \frac{v_0^2 \sqrt{2}}{16} [\cos \theta (\cos \theta + \sin \theta) - (\sin \theta - \cos \theta) \sin \theta] \\ &= \frac{v_0^2 \sqrt{2}}{16} (\cos^2 \theta - \sin^2 \theta + 2 \sin \theta \cos \theta) \\ &= \frac{v_0^2 \sqrt{2}}{16} (\cos 2\theta + \sin 2\theta). \end{aligned}$$

Therefore, $R'(\theta) = 0$ when $\cos 2\theta + \sin 2\theta = 0$. On the interval $45^\circ \leq \theta \leq 90^\circ$, $\cos 2\theta + \sin 2\theta = 0$ when $\theta = 67.5^\circ$. Evaluating f at the endpoints of the interval $[45^\circ, 90^\circ]$ and the critical number 67.5° yields

$$\begin{aligned} R(45^\circ) &= \frac{v_0^2 \sqrt{2}}{16} \cos 45^\circ (\sin 45^\circ - \cos 45^\circ) = 0 \\ R(67.5^\circ) &= \frac{v_0^2 \sqrt{2}}{16} \cos 67.5^\circ (\sin 67.5^\circ - \cos 67.5^\circ) \approx 0.0183v_0^2 \\ R(90^\circ) &= \frac{v_0^2 \sqrt{2}}{16} \cos 90^\circ (\sin 90^\circ - \cos 90^\circ) = 0. \end{aligned}$$

Therefore, the absolute maximum value of R on the interval $[45^\circ, 90^\circ]$ occurs when $\theta = 67.5^\circ$. The maximum value of R is approximately $0.0183v_0^2$.

- (b) The figure below displays the graph of R using $v_0 = 32$ ft/s. The dashed vertical line is drawn at $\theta = 67.5^\circ$.

- (c) Based on the graph in part (b), the angle that maximizes R is $\theta = 67.5^\circ$, and the maximum range is approximately

$$0.0183(32)^2 \approx 18.745 \text{ feet.}$$

74. Let $y = 10 \cosh \frac{x}{10} + 15$ and consider the interval $[-10, 10]$. Because y is continuous on this closed interval, the Extreme Value Theorem guarantees that y has an absolute maximum and an absolute minimum on $[-10, 10]$. The absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, y is differentiable everywhere, which means that the critical numbers of y occur where $y'(x) = 0$. Moreover,

$$y'(x) = \sinh \frac{x}{10} = 0$$

when $x = 0$. Evaluating y at the endpoints of the interval $[-10, 10]$ and the critical number 0 yields

$$y(-10) = 10 \cosh(-1) + 15 \approx 30.431$$

$$y(0) = 10 \cosh 0 + 15 = 25$$

$$y(10) = 10 \cosh 1 + 15 \approx 30.431.$$

Therefore, the absolute minimum value of y on the interval $[-10, 10]$ is 25; that is, the height of the cable at its lowest point is 25 m.

75. (a) Let $R = \frac{2v_0^2}{g} \sin \theta \cos \theta = \frac{v_0^2}{g} \sin 2\theta$, and consider the interval $[0^\circ, 90^\circ]$. Because R is continuous on this closed interval, the Extreme Value Theorem guarantees that R has an absolute maximum and an absolute minimum on $[0^\circ, 90^\circ]$. The absolute maximum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, R is differentiable everywhere, which means that the critical numbers of R occur where $R'(\theta) = 0$. Moreover,

$$R'(\theta) = \frac{2v_0^2}{g} \cos 2\theta = 0$$

when $\cos 2\theta = 0$. On the interval $[0^\circ, 90^\circ]$, $\cos 2\theta = 0$ when $\theta = 45^\circ$. Evaluating f at the endpoints of the interval $[0^\circ, 90^\circ]$ and the critical number 45° yields

$$R(0^\circ) = \frac{v_0^2}{g} \sin 0^\circ = 0$$

$$R(45^\circ) = \frac{v_0^2}{g} \sin 90^\circ = \frac{v_0^2}{g}$$

$$R(90^\circ) = \frac{v_0^2}{g} \sin 180^\circ = 0 = 0.$$

Therefore, the absolute maximum value of R is achieved when $\theta = 45^\circ$; that is, the golf ball achieves its maximum range when the golfer hits the ball at an angle of 45° .

- (b) With $v_0 = 91.1$ m/s and $g = 9.8$ m/s², the maximum range is

$$\frac{v_0^2}{g} = \frac{91.1^2}{9.8} \approx \boxed{846.858 \text{ m}}.$$

76. (a) Recall that

$$\lim_{\alpha \rightarrow 0} \frac{\sin \alpha}{\alpha} = 1,$$

so

$$\lim_{\alpha \rightarrow 0} I = I_0 \lim_{\alpha \rightarrow 0} \left(\frac{\sin \alpha}{\alpha} \right)^2 = I_0 \left(\lim_{\alpha \rightarrow 0} \frac{\sin \alpha}{\alpha} \right)^2 = I_0(1)^2 = \boxed{I_0}.$$

- (b) Differentiating the intensity formula with respect to α yields

$$I'(\alpha) = 2I_0 \frac{\sin \alpha}{\alpha} \cdot \frac{\alpha \cos \alpha - \sin \alpha}{\alpha^2} = 2I_0 \frac{\sin \alpha (\alpha \cos \alpha - \sin \alpha)}{\alpha^3}.$$

Though $I'(\alpha)$ does not exist when $\alpha = 0$, 0 is not in the domain of I , so 0 is not a critical number. Now, $I'(\alpha) = 0$ when either $\sin \alpha = 0$ (but $\alpha \neq 0$) or $\alpha \cos \alpha - \sin \alpha = 0$. When $\sin \alpha = 0$ (but $\alpha \neq 0$), it follows that I is also equal to 0 and because $I \geq 0$, these critical numbers correspond to absolute and local minima. On the other hand, when

$$\alpha \cos \alpha - \sin \alpha = 0 \quad \text{or equivalently} \quad \tan \alpha = \alpha,$$

I could have a local maximum or neither a maximum nor a minimum. As the graph of I shows (see below with $I_0 = 1$), every location where I has a horizontal tangent line corresponds to either a local maximum or a local minimum of I . The critical numbers corresponding to $\tan \alpha = \alpha$ must therefore be local maxima.

- (c) Based on the graph of the intensity in part (b), the intensity of light is not the same at each bright spot, but rather decreases as the angle α increases.

77. With $t = \sqrt{27 - 3q^2}$, the tax revenue R is given by

$$R = tq = q\sqrt{27 - 3q^2}.$$

The domain of this function is the set $\{q \mid -3 \leq q \leq 3\}$; however, from an economics standpoint, the quantity consumed must be greater than or equal to 0, so consider the function R over the interval $[0, 3]$. Because R is continuous on this closed interval, the Extreme Value Theorem guarantees that R has an absolute maximum and an absolute minimum on $[0, 3]$. The absolute maximum can only occur

at the endpoints of the interval or at the critical numbers inside the open interval. Now, the critical numbers of R occur where $R'(q) = 0$ or where $R'(q)$ does not exist. Moreover,

$$\begin{aligned} R'(q) &= q \cdot \frac{1}{2}(27 - 3q^2)^{-1/2}(-6q) + \sqrt{27 - 3q^2} \\ &= -\frac{3q^2}{\sqrt{27 - 3q^2}} + \sqrt{27 - 3q^2} = \frac{-3q^2 + 27 - 3q^2}{\sqrt{27 - 3q^2}} = \frac{27 - 6q^2}{\sqrt{27 - 3q^2}}, \end{aligned}$$

so $R'(q) = 0$ when $27 - 6q^2 = 0$, or when $q = \pm \frac{3\sqrt{2}}{2}$, and $R'(q)$ does not exist when $27 - 3q^2 = 0$, or when $q = \pm 3$. Of these numbers, only $\frac{3\sqrt{2}}{2}$ lies inside the open interval $(0, 3)$. Evaluating R at the endpoints of the interval $[0, 3]$ and the critical number $\frac{3\sqrt{2}}{2}$ yields

$$\begin{aligned} R(0) &= 0\sqrt{27} = 0 \\ R\left(\frac{3\sqrt{2}}{2}\right) &= \frac{3\sqrt{2}}{2} \sqrt{27 - 3\left(\frac{3\sqrt{2}}{2}\right)^2} = \frac{9\sqrt{3}}{2} \approx 7.794 \\ R(3) &= 3\sqrt{27 - 3(3)^2} = 0. \end{aligned}$$

Therefore, the absolute maximum value of R on the interval $[0, 3]$ is $\frac{9\sqrt{3}}{2}$ (and this occurs at the critical number $q = \frac{3\sqrt{2}}{2}$). Substituting this value for q into the formula for t gives

$$t = \sqrt{27 - 3\left(\frac{3\sqrt{2}}{2}\right)^2} = \frac{3\sqrt{6}}{2} \approx 3.674.$$

The maximum tax revenue is approximately 7.794, and this is produced with a tax rate of approximately 3.674.

78. With $t = 18 - 3q^2$, the tax revenue R is given by

$$R = tq = q(18 - 3q^2) = 18q - 3q^3.$$

The domain of this function is the set of all real numbers; however, from an economics standpoint, the quantity consumed must be greater than or equal to 0 and the tax rate must also be greater than or equal to 0, so consider the function R over the interval $[0, \sqrt{6}]$. Because R is continuous on this closed interval, the Extreme Value Theorem guarantees that R has an absolute maximum and an absolute minimum on $[0, \sqrt{6}]$. The absolute maximum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, R is differentiable everywhere, which means that the critical numbers of R occur where $R'(\theta) = 0$. Moreover,

$$R'(q) = 18 - 9q^2 = 9(2 - q^2),$$

so $R'(q) = 0$ when $2 - q^2 = 0$, or when $q = \pm\sqrt{2}$. As $q = -\sqrt{2}$ is not inside the open interval $(0, \sqrt{6})$, this number can be excluded. This leaves $\sqrt{2}$ as the only critical number. Evaluating R at the endpoints of the interval $[0, \sqrt{6}]$ and the critical number $\sqrt{2}$ yields

$$\begin{aligned} R(0) &= 0 \\ R(\sqrt{2}) &= \sqrt{2}(12) = 12\sqrt{2} \approx 16.971 \\ R(\sqrt{6}) &= 0. \end{aligned}$$

Therefore, the absolute maximum value of R on the interval $[0, \sqrt{6}]$ is $12\sqrt{2}$ (and this occurs at the critical number $q = \sqrt{2}$). Substituting this value for q into the formula for t gives

$$t = 18 - 3(\sqrt{2})^2 = 12.$$

The maximum tax revenue is approximately 16.971, and this is produced with a tax rate of 12.

79. Let $y = 15 \cosh \frac{x}{15} - 10$ and consider the interval $[-6, 6]$, thus assuming that the x -axis is placed along the ground with the two poles at $(-6, 0)$ and $(6, 0)$. Because y is continuous on this closed interval, the Extreme Value Theorem guarantees that y has an absolute maximum and an absolute minimum on $[-6, 6]$. The absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, y is differentiable everywhere, which means that the critical numbers of y occur where $y'(x) = 0$. Moreover,

$$y'(x) = \sinh \frac{x}{15} = 0$$

when $x = 0$. Evaluating y at the endpoints of the interval $[-6, 6]$ and the critical number 0 yields

$$\begin{aligned} y(-6) &= 15 \cosh \left(-\frac{6}{15} \right) - 10 \approx 6.216 \\ y(0) &= 15 \cosh 0 - 10 = 5 \\ y(6) &= 15 \cosh \left(\frac{6}{15} \right) - 10 \approx 6.216. \end{aligned}$$

Therefore, the absolute minimum value of y on the interval $[-6, 6]$ is 5; that is, the height of the cable at its lowest point is 5 m.

80. Let the amplitude of the harmonic motion be $A = 0.24$ m and the period be 4 s, so that

$$\omega = \frac{2\pi}{4} = \frac{\pi}{2}.$$

- (a) The position s is then given by

$$s(t) = 0.24 \cos \left(\frac{\pi}{2} t \right).$$

When $t = 0.5$ s,

$$s(0.5) = 0.24 \cos \left(\frac{\pi}{2} \cdot 0.5 \right) = 0.24 \cos \left(\frac{\pi}{4} \right) = \boxed{0.12\sqrt{2} \text{ m} \approx 0.170 \text{ m}}.$$

- (b) The velocity of the object is

$$v(t) = s'(t) = \boxed{-0.12\pi \sin \left(\frac{\pi}{2} t \right)}.$$

- (c) When $t = 0.5$ s,

$$v(0.5) = -0.12\pi \sin \left(\frac{\pi}{2} \cdot 0.5 \right) = -0.12\pi \sin \left(\frac{\pi}{4} \right) = \boxed{-0.06\pi\sqrt{2} \text{ m/s} \approx -0.267 \text{ m/s}}.$$

- (d) The acceleration of the object is

$$a(t) = v'(t) = \boxed{-0.06\pi^2 \cos \left(\frac{\pi}{2} t \right)}.$$

(e) When $t = 0.5$ s,

$$a(0.5) = -0.06\pi^2 \cos\left(\frac{\pi}{2} \cdot 0.5\right) = -0.06\pi^2 \cos\left(\frac{\pi}{4}\right) = -0.03\pi^2\sqrt{2} \approx -0.419 \text{ m/s}^2.$$

With $m = 1$ kg, $F = ma \approx -0.419$ N. The magnitude of the force is approximately $\boxed{0.419 \text{ N}}$, and the direction of the force is $\boxed{\text{toward the equilibrium position}}$ of $s = 0$.

(f) The position of the object will be -0.12 m when

$$-0.12 = s(t) = 0.24 \cos\left(\frac{\pi}{2}t\right) \quad \text{or when} \quad \cos\left(\frac{\pi}{2}t\right) = -\frac{1}{2}.$$

Starting from $\theta = 0$, $\cos \theta$ first reaches the value $-\frac{1}{2}$ when $\theta = \frac{2\pi}{3}$. Therefore,

$$\cos\left(\frac{\pi}{2}t\right)$$

first reaches the value $-\frac{1}{2}$ when

$$\frac{\pi}{2}t = \frac{2\pi}{3} \quad \text{or when} \quad \boxed{t = \frac{4}{3} \text{ seconds}}.$$

(g) When $t = 4/3$ s,

$$v\left(\frac{4}{3}\right) = -0.12\pi \sin\left(\frac{\pi}{2} \cdot \frac{4}{3}\right) = -0.12\pi \sin\left(\frac{2\pi}{3}\right) = \boxed{-0.06\pi\sqrt{3} \text{ m/s} \approx -0.326 \text{ m/s}}.$$

81. (a) Let $f(x) = \frac{x^3}{3} - 0.055x^2 + 0.0028x - 4$. Because f is a polynomial function, it is differentiable everywhere. Therefore, the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = x^2 - 0.11x + 0.0028 = 0$$

when

$$x = \frac{0.11 \pm \sqrt{0.11^2 - 4(0.0028)}}{2} = \frac{0.11 \pm \sqrt{0.0009}}{2} = \frac{0.11 \pm 0.03}{2} = \boxed{0.07, 0.04}.$$

- (b) Evaluating f at the endpoints of the closed interval $[-1, 1]$ and at the critical numbers 0.04 and 0.07 yields

$$\begin{aligned} f(-1) &\approx -4.391133333 \\ f(0.04) &\approx -3.999954667 \\ f(0.07) &\approx -3.999959167 \\ f(1) &\approx -3.718866667. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[-1, 1]$ is approximately $\boxed{-3.719}$ (which occurs at the endpoint $x = 1$), and the absolute minimum value is approximately $\boxed{-4.391}$ (which occurs at the endpoint $x = -1$).

- (c) The figure below displays the graph of f on the interval $[-1, 1]$.

82. (a) Let $y = x - \cosh^{-1} x$, and note the domain of y is the set $\{x|x \geq 1\}$. Now,

$$y' = 1 - \frac{1}{\sqrt{x^2 - 1}},$$

so, on the domain of y , $y'(x) = 0$ when $\sqrt{x^2 - 1} = 1$ or $x = \sqrt{2}$, and $y'(x)$ does not exist when $x = 1$. Because

$$\begin{aligned} y(1) &= 1 - \cosh^{-1} 1 = 1 - 0 = 1 \\ y(\sqrt{2}) &= \sqrt{2} - \cosh^{-1} \sqrt{2} \approx 0.533 \\ \lim_{x \rightarrow \infty} y(x) &= \infty, \end{aligned}$$

it follows that the minimum value of $y = x - \cosh^{-1} x$ is $\boxed{\sqrt{2} - \cosh^{-1} \sqrt{2}}$.

- (b) The figure below displays the graph of $y = x - \cosh^{-1} x$.

83. Let $f(x) = \sqrt{1+x^2} + |x-2|$, and consider the interval $[0, 3]$. Because f is continuous on this closed interval, the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute minimum on $[0, 3]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, the critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. On the interval $[0, 2)$, $x-2 < 0$, so $f(x) = \sqrt{1+x^2} - x + 2$ and

$$f'(x) = \frac{1}{2}(1+x^2)^{-1/2}(2x) - 1 = \frac{x}{\sqrt{1+x^2}} - 1.$$

This derivative exists and is never equal to zero for $0 \leq x < 2$, so there are no critical numbers on this interval. On the interval $(2, 3]$, $x - 2 > 0$, so $f(x) = \sqrt{1+x^2} + x - 2$ and

$$f'(x) = \frac{1}{2}(1+x^2)^{-1/2}(2x) + 1 = \frac{x}{\sqrt{1+x^2}} + 1.$$

This derivative exists and is never equal to zero for $2 < x \leq 3$, so there are no critical numbers on this interval. At $x = 2$, $f'(x)$ does not exist because of the $|x - 2|$ term, so 2 is a critical number of f . Evaluating f at the endpoints of the interval $[0, 3]$ and at the critical number 2 yields

$$\begin{aligned} f(0) &= \sqrt{1} + |0 - 2| = 1 + 2 = 3 \\ f(2) &= \sqrt{1+4} + 0 = \sqrt{5} \\ f(3) &= \sqrt{1+9} + |3 - 2| = \sqrt{10} + 1. \end{aligned}$$

Therefore, the absolute maximum value of the function f on the interval $[0, 3]$ is $\boxed{\sqrt{10} + 1}$ (and this occurs at the endpoint $\boxed{x = 3}$), while the absolute minimum value is $\boxed{\sqrt{5}}$ (and this occurs at the critical point $\boxed{x = 2}$).

84. Let $f(x) = Ax^2 + Bx + C$. Because the graph of f contains the points $(0, 2)$ and $(1, 8)$, it follows that $f(0) = 2$ and $f(1) = 8$. Now, $f(0) = C$, so $C = 2$, and $f(1) = A + B + C$, so $A + B + C = 8$ or $A + B = 6$. If f has a local minimum at 0, then 0 must be a critical number of f ; since the polynomial function f is differentiable everywhere, it follows that $f'(0) = 0$. Now, $f'(x) = 2Ax + B$, so $f'(0) = B$. Therefore, $B = 0$, and finally, $A = 6$. In summary, $\boxed{A = 6, B = 0, \text{ and } C = 2}$.

85. Let $f(x) = [(16 - x^2)(x^2 - 9)]^{1/2}$.

- (a) The domain of f is determined by the inequality $(16 - x^2)(x^2 - 9) \geq 0$. Now, $16 - x^2$ is positive for $-4 < x < 4$ and is negative for $|x| > 4$; on the other hand, $x^2 - 9$ is positive for $|x| > 3$ and is negative for $-3 < x < 3$. It follows that $16 - x^2$ and $x^2 - 9$ have the same sign for $-4 < x < -3$ and $3 < x < 4$. Additionally, $(16 - x^2)(x^2 - 9) = 0$ for $x = \pm 3$ and $x = \pm 4$. Therefore, the domain of f is the set

$$\boxed{\{x \mid -4 \leq x \leq -3 \text{ or } 3 \leq x \leq 4\}},$$

or in interval notation $\boxed{[-4, -3] \cup [3, 4]}$.

- (b) Note that

$$f(-x) = [(16 - (-x)^2)((-x)^2 - 9)]^{1/2} = [(16 - x^2)(x^2 - 9)]^{1/2} = f(x),$$

so f is an even function. To determine the absolute maximum value of f on its domain, it is therefore sufficient to consider the closed interval $[3, 4]$. The absolute maximum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, the critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Moreover,

$$\begin{aligned} f'(x) &= \frac{1}{2}[(16 - x^2)(x^2 - 9)]^{-1/2}[(16 - x^2)(2x) + (x^2 - 9)(-2x)] \\ &= \frac{1}{[(16 - x^2)(x^2 - 9)]^{1/2}} \cdot (16x - x^3 - x^3 + 9x) \\ &= \frac{x(25 - 2x^2)}{[(16 - x^2)(x^2 - 9)]^{1/2}}, \end{aligned}$$

so $f'(x) = 0$ when $25 - 2x^2 = 0$ or $x = \pm \frac{5\sqrt{2}}{2}$ and $f'(x)$ does not exist when $x = \pm 3$ and when $x = \pm 4$. Of these numbers, only $\frac{5\sqrt{2}}{2}$ is inside the open interval $(3, 4)$. Evaluating f at the

endpoints of the closed interval $[3, 4]$ and the critical number $\frac{5\sqrt{2}}{2}$ yields

$$\begin{aligned} f(3) &= 0 \\ f\left(\frac{5\sqrt{2}}{2}\right) &= \sqrt{\left(16 - \frac{25}{2}\right)\left(\frac{25}{2} - 9\right)} = \frac{7}{2} \\ f(4) &= 0. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[3, 4]$ is $\frac{7}{2}$. Because f is an even function, it follows that the absolute maximum value on the interval $[-4, -3]$ is also $\frac{7}{2}$, so the absolute maximum value of f on its domain is $\boxed{\frac{7}{2}}$.

86. Let $f(x) = \sqrt{x(2-x)}$. Because $x(2-x) \geq 0$ for $0 \leq x \leq 2$, the domain of f is the set $\{x | 0 \leq x \leq 2\}$. On this closed interval, f is continuous, so the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute minimum on $[0, 2]$. Without calculus, note that $f(x) = \sqrt{x(2-x)} \geq 0$ on its domain and $f(0) = f(2) = 0$. It follows that 0 is the absolute minimum value of f . As for the absolute maximum value, note that the graph of $y = x(2-x) = 2x - x^2$ is a downward opening parabola with its vertex at $(1, 1)$; therefore, $2x - x^2 \leq 1$, so that $\sqrt{x(2-x)} \leq 1$, and 1 is the absolute maximum value of f . Next, using calculus, the absolute maximum and absolute minimum can only occur at the endpoints of the interval $[0, 2]$ or at the critical numbers inside the open interval. Now, the critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Moreover,

$$f'(x) = \frac{1}{2}[x(2-x)]^{-1/2}(2-2x) = \frac{1-x}{\sqrt{x(2-x)}},$$

so $f'(x) = 0$ when $x = 1$ and $f'(x)$ does not exist when $x = 0$ and $x = 2$. Of these numbers, only $x = 1$ is inside the open interval $(0, 2)$. Evaluating f at the endpoints of the closed interval $[0, 2]$ and the critical number 1 yields

$$\begin{aligned} f(0) &= 0 \\ f(1) &= \sqrt{1(1)} = 1 \\ f(2) &= 0. \end{aligned}$$

Therefore, the absolute maximum value of f on its domain is $\boxed{1}$ (and this occurs at the critical number $x = 1$), while the absolute minimum value is $\boxed{0}$ (and this occurs at both endpoints $x = 0$ and $x = 2$).

87. (a) $\boxed{\text{Not necessarily true}}$. Just because a function is continuous on a closed interval $[a, b]$ is no guarantee that the function is differentiable on (a, b) .
- (b) $\boxed{\text{Not necessarily true}}$. An absolute maximum can occur at an endpoint of the interval $[a, b]$; even if the absolute maximum occurs at a critical number, the derivative might not exist at that critical number.
- (c) $\boxed{\text{True}}$. This is the definition of continuity on the open interval (a, b) .
- (d) $\boxed{\text{Not necessarily true}}$. Just because a function is continuous on a closed interval $[a, b]$ is no guarantee that the function is differentiable on (a, b) ; even if the function is differentiable, the derivative does not need to equal 0 for some x , $a \leq x \leq b$.
- (e) $\boxed{\text{True}}$. This follows from the Extreme Value Theorem.
88. Let f be a function defined on an interval I . An extreme value of f , whether absolute or local, is a value of f that is larger than or equal to in the case of a maximum or smaller than or equal to in

the case of a minimum other values of f . To be an absolute extreme value, the value of f must be the largest or smallest value taken on by f throughout the entire interval I . In contrast, to be a local extreme value, the value of f only needs to be the largest or smallest value taken on by f in some open interval contained inside I .

89. The absolute extreme values of a continuous function defined on a closed interval $[a, b]$ can only occur at the endpoints of the interval or at the critical numbers inside the open interval (a, b) . Therefore, first determine the critical numbers of the function: determine where inside the open interval that the derivative is equal to zero and where the derivative does not exist. Next, evaluate the function at the endpoints of the interval and at the critical numbers inside the interval. Finally, identify the absolute maximum value (the largest of the function values obtained in the previous step) and the absolute minimum value (the smallest of the function values obtained in the previous step).
90. By definition, a local maximum for a function f occurs at c when $f(c) \geq f(x)$ for all x in some open interval containing c . Similarly, f has a local minimum at c when $f(c) \leq f(x)$ for all x in some open interval containing c . In each case, it is required that f be defined in an open interval containing c . Here, the function is defined on the closed interval $[a, b]$, so there is no open interval containing a on which f is defined. It is therefore impossible for $f(a)$ to be a local extreme value of f – though it is still possible for $f(a)$ to be an absolute extreme value of f .
91. Suppose f has a local minimum at c . Then, for all x in an open interval containing c , $f(c) \leq f(x)$. Multiplying this inequality by -1 yields $-f(c) \geq -f(x)$. Now, let $g(x) = -f(x)$. Then the last inequality becomes $g(c) \geq g(x)$ for all x in an open interval containing c . Therefore, g has a local maximum at c .
92. Suppose f has a local minimum at c . Then $f(c) \leq f(x)$ for all x in some open interval containing c . Equivalently, $f(x) - f(c) \geq 0$. The derivative of f at c may be written as

$$f'(c) = \lim_{x \rightarrow c} \frac{f(x) - f(c)}{x - c},$$

provided the limit exists. If this limit does not exist, then $f'(c)$ does not exist and there is nothing further to prove. If this limit does exist, then the two one-sided limits

$$\lim_{x \rightarrow c^-} \frac{f(x) - f(c)}{x - c} \quad \text{and} \quad \lim_{x \rightarrow c^+} \frac{f(x) - f(c)}{x - c}$$

must exist and be equal to one another. For the limit from the left, $x < c$, so $x - c < 0$,

$$\frac{f(x) - f(c)}{x - c} \leq 0, \quad \text{and} \quad \lim_{x \rightarrow c^-} \frac{f(x) - f(c)}{x - c} \leq 0.$$

For the limit from the right, $x > c$, so $x - c > 0$,

$$\frac{f(x) - f(c)}{x - c} \geq 0, \quad \text{and} \quad \lim_{x \rightarrow c^+} \frac{f(x) - f(c)}{x - c} \geq 0.$$

For the two one-sided limits to be equal, they must equal zero; therefore

$$f'(c) = \lim_{x \rightarrow c} \frac{f(x) - f(c)}{x - c} = 0.$$

Challenge Problems

93. (a) Let a , b , c , and d be real numbers, $n \geq 1$ an integer, and $f(x) = \frac{ax^{2n} + b}{cx^n + d}$. If $a = 0$, then

$$f(x) = \frac{b}{cx^n + d} = b(cx^n + d)^{-1} \quad \text{and} \quad f'(x) = -bcn x^{n-1} (cx^n + d)^{-2}.$$

Now, $f'(x)$ does not exist when $cx^n + d = 0$, but any x that satisfies this equation is not in the domain of f , so it cannot be a critical number. Therefore, the only critical numbers of f occur where $f'(x) = 0$, which is at $x = 0$. So, if $a = 0$, then f has only one critical number.

Next, consider the case $c = 0$ but $d \neq 0$ (c and d cannot be simultaneously equal to zero, as that would cause division by zero for all x). Then

$$f(x) = \frac{a}{d}x^{2n} + \frac{b}{d} \quad \text{and} \quad f'(x) = \frac{2an}{d}x^{2n-1}.$$

Now, $f'(x)$ exists for all x and is equal to zero only at $x = 0$. When $c = 0$ but $d \neq 0$, f has only one critical number.

Finally, suppose $a \neq 0$ and $c \neq 0$. Then

$$\begin{aligned} f'(x) &= \frac{(cx^n + d)(2anx^{2n-1}) - (ax^{2n} + b)(cnx^{n-1})}{(cx^n + d)^2} \\ &= \frac{2acnx^{3n-1} + 2adnx^{2n-1} - acnx^{3n-1} - bcnx^{n-1}}{(cx^n + d)^2} \\ &= \frac{acnx^{n-1} \left(x^{2n} + 2\frac{d}{c}x^n - \frac{b}{a} \right)}{(cx^n + d)^2}. \end{aligned}$$

Now, $f'(x)$ does not exist when $cx^n + d = 0$, but any x that satisfies this equation is not in the domain of f , so it cannot be a critical number. Therefore, the only critical numbers of f occur where $f'(x) = 0$. Clearly, $f'(x) = 0$ when $x = 0$. Any other critical numbers are the zeros of the function

$$g(x) = x^{2n} + 2\frac{d}{c}x^n - \frac{b}{a} = \left(x^n + \frac{d}{c} \right)^2 - \left(\frac{b}{a} + \frac{d^2}{c^2} \right).$$

The number of zeros of g depends on the values of a , b , c , and d :

- i. If $\frac{b}{a} + \frac{d^2}{c^2} < 0$, g has no zeros.
- ii. If $\frac{b}{a} + \frac{d^2}{c^2} = 0$, then g has one zero if n is odd (which will not be 0 provided $d \neq 0$) but 2 zeroes if n is even and $d/c < 0$.
- iii. If $\frac{b}{a} + \frac{d^2}{c^2} > 0$, then g has two zeros if n is odd (neither of which will be 0 provided $b \neq 0$) but can have 0, 2, or 4 zeros if n is even depending on the signs of

$$-\frac{d}{c} + \sqrt{\frac{b}{a} + \frac{d^2}{c^2}} \quad \text{and} \quad -\frac{d}{c} - \sqrt{\frac{b}{a} + \frac{d^2}{c^2}}.$$

It follows that f can have at most five critical numbers.

- (b) Based on part (a), in order for f to have five critical numbers, n must be even and

$$\frac{b}{a} + \frac{d^2}{c^2}, \quad -\frac{d}{c} + \sqrt{\frac{b}{a} + \frac{d^2}{c^2}}, \quad \text{and} \quad -\frac{d}{c} - \sqrt{\frac{b}{a} + \frac{d^2}{c^2}}$$

must all be positive. Answers will vary, but one choice of parameter values is $n = 2$, $a = 1$, $b = -1$, $c = 1$, and $d = -2$. Note that

$$\begin{aligned} \frac{b}{a} + \frac{d^2}{c^2} &= -1 + 4 = 3 > 0 \\ -\frac{d}{c} + \sqrt{\frac{b}{a} + \frac{d^2}{c^2}} &= 2 + \sqrt{3} > 0 \\ -\frac{d}{c} - \sqrt{\frac{b}{a} + \frac{d^2}{c^2}} &= 2 - \sqrt{3} > 0. \end{aligned}$$

The function

$$f(x) = \frac{x^4 - 1}{x^2 - 2}$$

has exactly five critical numbers:

$$0, \quad \pm\sqrt{2 + \sqrt{3}}, \quad \text{and} \quad \pm\sqrt{2 - \sqrt{3}}.$$

4.3: The Mean Value Theorem

Concepts and Vocabulary

1. False. If a function f is defined and continuous on a closed interval $[a, b]$, differentiable on the open interval (a, b) , and if $f(a) = f(b)$, then Rolle's Theorem guarantees that there is at least one number c in the interval (a, b) for which $f'(c) = 0$. The conclusion of Rolle's Theorem involves the derivative of the function, not the function itself.
2. Answers will vary. Here is one possible response. For a function f that is continuous on a closed interval $[a, b]$ and differentiable on the open interval (a, b) , the Mean Value Theorem guarantees that there is at least one tangent line to the graph of f on the open interval (a, b) which is parallel to the secant line between the points $(a, f(a))$ and $(b, f(b))$.
3. True. If two functions f and g are differentiable on an open interval (a, b) and if $f'(x) = g'(x)$ for all numbers x in (a, b) , then f and g differ by a constant on (a, b) .
4. False. When the derivative f' is positive on an open interval I , then f is **increasing** on I .

Skill Building

5. Let $f(x) = x^2 - 3x$. The polynomial function f is continuous and differentiable everywhere, so it is continuous on the closed interval $[0, 3]$ and differentiable on the open interval $(0, 3)$. Additionally,

$$f(0) = 0 \quad \text{and} \quad f(3) = 3^2 - 3(3) = 0,$$

so $f(0) = f(3)$. The function f therefore satisfies all three conditions of Rolle's Theorem on the interval $[0, 3]$. Now, $f'(x) = 2x - 3$, so $f'(c) = 0$ when $c = \frac{3}{2}$.

6. Let $f(x) = x^2 + 2x$. The polynomial function f is continuous and differentiable everywhere, so it is continuous on the closed interval $[-2, 0]$ and differentiable on the open interval $(-2, 0)$. Additionally,

$$f(-2) = (-2)^2 + 2(-2) = 0 \quad \text{and} \quad f(0) = 0,$$

so $f(-2) = f(0)$. The function f therefore satisfies all three conditions of Rolle's Theorem on the interval $[-2, 0]$. Now, $f'(x) = 2x + 2$, so $f'(c) = 0$ when $c = -1$.

7. Let $g(x) = x^2 - 2x - 2$. The polynomial function g is continuous and differentiable everywhere, so it is continuous on the closed interval $[0, 2]$ and differentiable on the open interval $(0, 2)$. Additionally,

$$g(0) = -2 \quad \text{and} \quad g(2) = 2^2 - 2(2) - 2 = -2,$$

so $g(0) = g(2)$. The function g therefore satisfies all three conditions of Rolle's Theorem on the interval $[0, 2]$. Now, $g'(x) = 2x - 2$, so $g'(c) = 0$ when $c = 1$.

8. Let $g(x) = x^2 + 1$. The polynomial function g is continuous and differentiable everywhere, so it is continuous on the closed interval $[-1, 1]$ and differentiable on the open interval $(-1, 1)$. Additionally,

$$g(-1) = (-1)^2 + 1 = 2 \quad \text{and} \quad g(1) = 1^2 + 1 = 2,$$

so $g(-1) = g(1)$. The function g therefore satisfies all three conditions of Rolle's Theorem on the interval $[-1, 1]$. Now, $g'(x) = 2x$, so $g'(c) = 0$ when $c = 0$.

9. Let $f(x) = x^3 - x$. The polynomial function f is continuous and differentiable everywhere, so it is continuous on the closed interval $[-1, 0]$ and differentiable on the open interval $(-1, 0)$. Additionally,

$$f(-1) = (-1)^3 - (-1) = 0 \quad \text{and} \quad f(0) = 0,$$

so $f(-1) = f(0)$. The function f therefore satisfies all three conditions of Rolle's Theorem on the interval $[-1, 0]$. Now, $f'(x) = 3x^2 - 1$, so $f'(c) = 0$ when $c = \pm \frac{\sqrt{3}}{3}$. Of these two numbers, only

$$\boxed{c = -\frac{\sqrt{3}}{3}} \text{ is in the interval } [-1, 0].$$

10. Let $f(x) = x^3 - 4x$. The polynomial function f is continuous and differentiable everywhere, so it is continuous on the closed interval $[-2, 2]$ and differentiable on the open interval $(-2, 2)$. Additionally,

$$f(-2) = (-2)^3 - 4(-2) = 0 \quad \text{and} \quad f(2) = 2^3 - 4(2) = 0,$$

so $f(-2) = f(2)$. The function f therefore satisfies all three conditions of Rolle's Theorem on the

interval $[-2, 2]$. Now, $f'(x) = 3x^2 - 4$, so $f'(c) = 0$ when $\boxed{c = \pm \frac{2\sqrt{3}}{3}}$.

11. Let $f(t) = t^3 - t + 2$. The polynomial function f is continuous and differentiable everywhere, so it is continuous on the closed interval $[-1, 1]$ and differentiable on the open interval $(-1, 1)$. Additionally,

$$f(-1) = (-1)^3 - (-1) + 2 = 2 \quad \text{and} \quad f(1) = 1^3 - 1 + 2 = 2,$$

so $f(-1) = f(1)$. The function f therefore satisfies all three conditions of Rolle's Theorem on the

interval $[-1, 1]$. Now, $f'(t) = 3t^2 - 1$, so $f'(c) = 0$ when $\boxed{c = \pm \frac{\sqrt{3}}{3}}$.

12. Let $f(t) = t^4 - 3$. The polynomial function f is continuous and differentiable everywhere, so it is continuous on the closed interval $[-2, 2]$ and differentiable on the open interval $(-2, 2)$. Additionally,

$$f(-2) = (-2)^4 - 3 = 13 \quad \text{and} \quad f(2) = 2^4 - 3 = 13,$$

so $f(-2) = f(2)$. The function f therefore satisfies all three conditions of Rolle's Theorem on the interval $[-2, 2]$. Now, $f'(t) = 4t^3$, so $f'(c) = 0$ when $\boxed{c = 0}$.

13. Let $s(t) = t^4 - 2t^2 + 1$. The polynomial function s is continuous and differentiable everywhere, so it is continuous on the closed interval $[-2, 2]$ and differentiable on the open interval $(-2, 2)$. Additionally,

$$s(-2) = (-2)^4 - 2(-2)^2 + 1 = 9 \quad \text{and} \quad s(2) = 2^4 - 2(2)^2 + 1 = 9,$$

so $s(-2) = s(2)$. The function s therefore satisfies all three conditions of Rolle's Theorem on the interval $[-2, 2]$. Now, $s'(t) = 4t^3 - 4t = 4t(t^2 - 1)$, so $s'(c) = 0$ when $\boxed{c = 0 \text{ or } c = \pm 1}$.

14. Let $s(t) = t^4 + t^2$. The polynomial function s is continuous and differentiable everywhere, so it is continuous on the closed interval $[-2, 2]$ and differentiable on the open interval $(-2, 2)$. Additionally,

$$s(-2) = (-2)^4 + (-2)^2 = 20 \quad \text{and} \quad s(2) = 2^4 + (2)^2 = 20,$$

so $s(-2) = s(2)$. The function s therefore satisfies all three conditions of Rolle's Theorem on the interval $[-2, 2]$. Now, $s'(t) = 4t^3 + 2t = 2t(2t^2 + 1)$, so $s'(c) = 0$ when $\boxed{c = 0}$.

15. Let $f(x) = \sin(2x)$. The trigonometric function f is continuous and differentiable everywhere, so it is continuous on the closed interval $[0, \pi]$ and differentiable on the open interval $(0, \pi)$. Additionally,

$$f(0) = \sin 0 = 0 \quad \text{and} \quad f(\pi) = \sin(2\pi) = 0,$$

so $f(0) = f(\pi)$. The function f therefore satisfies all three conditions of Rolle's Theorem on the interval

$[0, \pi]$. Now, $f'(x) = 2\cos(2x)$, so $f'(c) = 0$ on the interval $(0, \pi)$ when $\boxed{c = \frac{\pi}{4} \text{ or } c = \frac{3\pi}{4}}$.

16. Let $f(x) = \sin x + \cos x$. The function f is the sum of the trigonometric functions $\sin x$ and $\cos x$, both of which are continuous and differentiable everywhere. Therefore, f is continuous and differentiable everywhere, so it is continuous on the closed interval $[0, 2\pi]$ and differentiable on the open interval $(0, 2\pi)$. Additionally,

$$f(0) = \sin 0 + \cos 0 = 0 + 1 = 1 \quad \text{and} \quad f(2\pi) = \sin(2\pi) + \cos(2\pi) = 0 + 1 = 1,$$

so $f(0) = f(2\pi)$. The function f therefore satisfies all three conditions of Rolle's Theorem on the interval $[0, 2\pi]$. Now, $f'(x) = \cos x - \sin x$, so $f'(c) = 0$ on the interval $(0, 2\pi)$ when $c = \frac{\pi}{4}$ or $c = \frac{5\pi}{4}$.

17. Let $f(x) = x^2 - 2x + 1$. Though the polynomial function f is continuous on the closed interval $[-2, 1]$ and differentiable on the open interval $(-2, 1)$,

$$f(-2) = (-2)^2 - 2(-2) + 1 = 9 \quad \text{and} \quad f(1) = 1 - 2 + 1 = 0.$$

Therefore, $f(-2) \neq f(1)$, so Rolle's Theorem does not apply for the function f on the interval $[-2, 1]$.

18. Let $f(x) = x^3 - 3x$. Though the polynomial function f is continuous on the closed interval $[2, 4]$ and differentiable on the open interval $(2, 4)$,

$$f(2) = 2^3 - 3(2) = 2 \quad \text{and} \quad f(4) = 4^3 - 3(4) = 52.$$

Therefore, $f(2) \neq f(4)$, so Rolle's Theorem cannot be applied to the function f on the interval $[2, 4]$.

19. Let $f(x) = x^{1/3} - x$. Though f is continuous on the closed interval $[-1, 1]$,

$$f'(x) = \frac{1}{3}x^{-2/3} - 1,$$

so f is not differentiable at 0 and therefore is not differentiable on the open interval $(-1, 1)$. Consequently, Rolle's Theorem cannot be applied to the function f on the interval $[-1, 1]$.

20. Let $f(x) = x^{2/5}$. Though f is continuous on the closed interval $[-1, 1]$,

$$f'(x) = \frac{2}{5}x^{-3/5},$$

so f is not differentiable at 0 and therefore is not differentiable on the open interval $(-1, 1)$. Consequently, Rolle's Theorem cannot be applied to the function f on the interval $[-1, 1]$.

21. Let $f(x) = x^2 + 1$. The polynomial function f is continuous and differentiable everywhere, so it is continuous on the closed interval $[0, 2]$ and differentiable on the open interval $(0, 2)$. The function f therefore satisfies the conditions of the Mean Value Theorem on the interval $[0, 2]$. Now,

$$f'(x) = 2x \quad \text{and} \quad \frac{f(b) - f(a)}{b - a} = \frac{f(2) - f(0)}{2 - 0} = \frac{5 - 1}{2} = 2,$$

so

$$f'(c) = \frac{f(b) - f(a)}{b - a} \quad \text{when} \quad 2c = 2,$$

or when $c = 1$.

22. Let $f(x) = x + 2 + \frac{3}{x-1}$. The function f is continuous and differentiable on the set $\{x | x \neq 1\}$, so it is continuous on the closed interval $[2, 7]$ and differentiable on the open interval $(2, 7)$. The function f therefore satisfies the conditions of the Mean Value Theorem on the interval $[2, 7]$. Now,

$$f'(x) = 1 - \frac{3}{(x-1)^2} \quad \text{and} \quad \frac{f(b) - f(a)}{b - a} = \frac{f(7) - f(2)}{7 - 2} = \frac{\frac{19}{2} - 7}{5} = \frac{1}{2},$$

so

$$f'(c) = \frac{f(b) - f(a)}{b - a} \quad \text{when} \quad 1 - \frac{3}{(c-1)^2} = \frac{1}{2}.$$

Therefore,

$$\begin{aligned} \frac{3}{(c-1)^2} &= \frac{1}{2} \\ (c-1)^2 &= 6 \\ c &= 1 \pm \sqrt{6}. \end{aligned}$$

Of these numbers, only $\boxed{c = 1 + \sqrt{6}}$ is in the interval $(2, 7)$.

23. Let $f(x) = \ln \sqrt{x} = \frac{1}{2} \ln x$. The function f is continuous and differentiable on the set $\{x|x > 0\}$, so it is continuous on the closed interval $[1, e]$ and differentiable on the open interval $(1, e)$. The function f therefore satisfies the conditions of the Mean Value Theorem on the interval $[1, e]$. Now,

$$f'(x) = \frac{1}{2x} \quad \text{and} \quad \frac{f(b) - f(a)}{b - a} = \frac{f(e) - f(1)}{e - 1} = \frac{\frac{1}{2} - 0}{e - 1} = \frac{1}{2(e - 1)},$$

so

$$f'(c) = \frac{f(b) - f(a)}{b - a} \quad \text{when} \quad \frac{1}{2c} = \frac{1}{2(e - 1)},$$

or when $\boxed{c = e - 1}$. Note that $e - 1 \approx 1.718 > 1$.

24. Let $f(x) = xe^x$. The function f is continuous and differentiable everywhere, so it is continuous on the closed interval $[0, 1]$ and differentiable on the open interval $(0, 1)$. The function f therefore satisfies the conditions of the Mean Value Theorem on the interval $[0, 1]$. Now,

$$f'(x) = xe^x + e^x \quad \text{and} \quad \frac{f(b) - f(a)}{b - a} = \frac{f(1) - f(0)}{1 - 0} = \frac{e - 0}{1} = e,$$

so

$$f'(c) = \frac{f(b) - f(a)}{b - a} \quad \text{when} \quad e^c(c + 1) = e,$$

or when $\boxed{c \approx 0.557}$. This value was obtained using the computer algebra system *Maple*.

25. Let $f(x) = x^3 - 5x^2 + 4x - 2$. The polynomial function f is continuous and differentiable everywhere, so it is continuous on the closed interval $[1, 3]$ and differentiable on the open interval $(1, 3)$. The function f therefore satisfies the conditions of the Mean Value Theorem on the interval $[1, 3]$. Now,

$$f'(x) = 3x^2 - 10x + 4 \quad \text{and} \quad \frac{f(b) - f(a)}{b - a} = \frac{f(3) - f(1)}{3 - 1} = \frac{-8 - (-2)}{2} = -3,$$

so

$$f'(c) = \frac{f(b) - f(a)}{b - a} \quad \text{when} \quad 3c^2 - 10c + 4 = -3.$$

Therefore,

$$\begin{aligned} 3c^2 - 10c + 7 &= 0 \\ (3c - 7)(c - 1) &= 0 \\ c &= \frac{7}{3}, 1. \end{aligned}$$

Of these numbers, only $\boxed{c = \frac{7}{3}}$ is in the interval $(1, 3)$.

26. Let $f(x) = x^3 - 7x^2 + 5x$. The polynomial function f is continuous and differentiable everywhere, so it is continuous on the closed interval $[-2, 2]$ and differentiable on the open interval $(-2, 2)$. The function f therefore satisfies the conditions of the Mean Value Theorem on the interval $[-2, 2]$. Now,

$$f'(x) = 3x^2 - 14x + 5 \quad \text{and} \quad \frac{f(b) - f(a)}{b - a} = \frac{f(2) - f(-2)}{2 - (-2)} = \frac{-10 - (-46)}{4} = 9,$$

so

$$f'(c) = \frac{f(b) - f(a)}{b - a} \quad \text{when} \quad 3c^2 - 14c + 5 = 9.$$

Therefore, $3c^2 - 14c - 4 = 0$ and

$$c = \frac{14 \pm \sqrt{(-14)^2 - 4(3)(-4)}}{2(3)} = \frac{14 \pm \sqrt{244}}{6} = \frac{7 \pm \sqrt{61}}{3}.$$

Of these numbers, only $c = \frac{7 - \sqrt{61}}{3} \approx -0.270$ is in the interval $(-2, 2)$. Note that $c = \frac{7 + \sqrt{61}}{3} \approx 4.937$.

27. Let $f(x) = \frac{x+1}{x} = 1 + \frac{1}{x}$. The function f is continuous and differentiable on the set $\{x|x \neq 0\}$, so it is continuous on the closed interval $[1, 3]$ and differentiable on the open interval $(1, 3)$. The function f therefore satisfies the conditions of the Mean Value Theorem on the interval $[1, 3]$. Now,

$$f'(x) = -\frac{1}{x^2} \quad \text{and} \quad \frac{f(b) - f(a)}{b - a} = \frac{f(3) - f(1)}{3 - 1} = \frac{\frac{4}{3} - 2}{2} = -\frac{1}{3},$$

so

$$f'(c) = \frac{f(b) - f(a)}{b - a} \quad \text{when} \quad -\frac{1}{c^2} = -\frac{1}{3}.$$

Therefore, $c^2 = 3$ and $c = \pm\sqrt{3}$. Of these numbers, only $c = \sqrt{3}$ is in the interval $(1, 3)$.

28. Let $f(x) = \frac{x^2}{x+1}$. The function f is continuous and differentiable on the set $\{x|x \neq -1\}$, so it is continuous on the closed interval $[0, 1]$ and differentiable on the open interval $(0, 1)$. The function f therefore satisfies the conditions of the Mean Value Theorem on the interval $[0, 1]$. Now,

$$f'(x) = \frac{(x+1)(2x) - x^2}{(x+1)^2} = \frac{x^2 + 2x}{(x+1)^2} \quad \text{and} \quad \frac{f(b) - f(a)}{b - a} = \frac{f(1) - f(0)}{1 - 0} = \frac{\frac{1}{2} - 0}{1} = \frac{1}{2},$$

so

$$f'(c) = \frac{f(b) - f(a)}{b - a} \quad \text{when} \quad \frac{c^2 + 2c}{(c+1)^2} = \frac{1}{2}.$$

Therefore,

$$\begin{aligned} 2(c^2 + 2c) &= (c+1)^2 \\ 2c^2 + 4c &= c^2 + 2c + 1 \\ c^2 + 2c &= 1 \\ c^2 + 2c + 1 &= 2 \\ (c+1)^2 &= 2 \end{aligned}$$

so that $c = -1 \pm \sqrt{2}$. Of these numbers, only $c = -1 + \sqrt{2}$ is in the interval $(0, 1)$.

29. Let $f(x) = \sqrt[3]{x^2}$. The function f is continuous on the set of all real numbers and differentiable on the set $\{x|x \neq 0\}$, so it is continuous on the closed interval $[1, 8]$ and differentiable on the open interval $(1, 8)$. The function f therefore satisfies the conditions of the Mean Value Theorem on the interval $[1, 8]$. Now,

$$f'(x) = \frac{2}{3}x^{-1/3} \quad \text{and} \quad \frac{f(b) - f(a)}{b - a} = \frac{f(8) - f(1)}{8 - 1} = \frac{4 - 1}{7} = \frac{3}{7},$$

so

$$f'(c) = \frac{f(b) - f(a)}{b - a} \quad \text{when} \quad \frac{2}{3}c^{-1/3} = \frac{3}{7}.$$

Therefore, $c^{1/3} = \frac{14}{9}$ and $\boxed{c = \left(\frac{14}{9}\right)^3 = \frac{2744}{729}}$.

30. Let $f(x) = \sqrt{x-2}$. The function f is continuous on the set $\{x|x \leq 2\}$ and differentiable on the set $\{x|x > 2\}$, so it is continuous on the closed interval $[2, 4]$ and differentiable on the open interval $(2, 4)$. The function f therefore satisfies the conditions of the Mean Value Theorem on the interval $[2, 4]$. Now,

$$f'(x) = \frac{1}{2\sqrt{x-2}} \quad \text{and} \quad \frac{f(b) - f(a)}{b - a} = \frac{f(4) - f(2)}{4 - 2} = \frac{\sqrt{2} - 0}{2} = \frac{\sqrt{2}}{2},$$

so

$$f'(c) = \frac{f(b) - f(a)}{b - a} \quad \text{when} \quad \frac{1}{2\sqrt{c-2}} = \frac{\sqrt{2}}{2}.$$

Therefore, $\sqrt{c-2} = \frac{1}{\sqrt{2}}$ and $\boxed{c = \frac{5}{2}}$.

31. Let $f(x) = x^3 + 6x^2 + 12x + 1$. The polynomial function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = 3x^2 + 12x + 12 = 3(x^2 + 4x + 4) = 3(x+2)^2,$$

so -2 is the only critical number. The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. Because $f'(x) > 0$ for all $x \neq -2$, it follows that f is increasing on the intervals $(-\infty, -2)$ and $(-2, \infty)$. Since f is continuous on its domain, we can say that f is increasing on $(-\infty, \infty)$.

32. Let $f(x) = -x^3 + 3x^2 + 4$. The polynomial function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = -3x^2 + 6x = 3x(2 - x),$$

so 0 and 2 are critical numbers. The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. These inequalities are solved by using the critical numbers 0 and 2 to form three intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $3x$	Sign of $2 - x$	Sign of $f'(x)$	Conclusion
$(-\infty, 0)$	—	+	—	f is decreasing
$(0, 2)$	+	+	+	f is increasing
$(2, \infty)$	+	—	—	f is decreasing

Therefore, f is increasing on the interval $(0, 2)$ and decreasing on the intervals $(-\infty, 0)$ and $(2, \infty)$. Since f is continuous on its domain, we can say that f is increasing on the interval $[0, 2]$ and decreasing on the intervals $(-\infty, 0]$ and $[2, \infty)$.

33. Let $f(x) = x^{2/3}(x^2 - 4)$. The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now,

$$f'(x) = x^{2/3}(2x) + (x^2 - 4) \cdot \frac{2}{3}x^{-1/3} = \frac{3x(2x) + 2(x^2 - 4)}{3x^{1/3}} = \frac{8x^2 - 8}{3x^{1/3}} = \frac{8(x-1)(x+1)}{3x^{1/3}},$$

so -1 , 0 , and 1 are the critical numbers. The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. These inequalities are solved by using the critical numbers -1 , 0 , and 1 to form four intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $8(x-1)$	Sign of $x+1$	Sign of $3x^{1/3}$	Sign of $f'(x)$	Conclusion
$(-\infty, -1)$	$-$	$-$	$-$	$-$	f is decreasing
$(-1, 0)$	$-$	$+$	$-$	$+$	f is increasing
$(0, 1)$	$-$	$+$	$+$	$-$	f is decreasing
$(1, \infty)$	$+$	$+$	$+$	$+$	f is increasing

Therefore, f is increasing on the intervals $(-1, 0)$ and $(1, \infty)$ and decreasing on the intervals $(-\infty, -1)$ and $(0, 1)$. Since f is continuous on its domain, we can say that f is increasing on the intervals $[-1, 0]$ and $[1, \infty)$ and decreasing on the intervals $(-\infty, -1]$ and $[0, 1]$.

34. Let $f(x) = x^{1/3}(x^2 - 7)$. The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now,

$$f'(x) = x^{1/3}(2x) + (x^2 - 7) \cdot \frac{1}{3}x^{-2/3} = \frac{3x(2x) + (x^2 - 7)}{3x^{2/3}} = \frac{7x^2 - 7}{3x^{2/3}} = \frac{7(x-1)(x+1)}{3x^{2/3}},$$

so -1 , 0 , and 1 are the critical numbers. The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. These inequalities are solved by using the critical numbers -1 , 0 , and 1 to form four intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $7(x-1)$	Sign of $x+1$	Sign of $3x^{2/3}$	Sign of $f'(x)$	Conclusion
$(-\infty, -1)$	$-$	$-$	$+$	$+$	f is increasing
$(-1, 0)$	$-$	$+$	$+$	$-$	f is decreasing
$(0, 1)$	$-$	$+$	$+$	$-$	f is decreasing
$(1, \infty)$	$+$	$+$	$+$	$+$	f is increasing

Therefore, f is increasing on the intervals $(-\infty, -1)$ and $(1, \infty)$ and decreasing on the intervals $(-1, 0)$ and $(0, 1)$. Since f is continuous on its domain, we can say that f is increasing on the intervals $(-\infty, -1]$ and $[1, \infty)$ and decreasing on the interval $[-1, 1]$.

35. Let

$$f(x) = |x^3 + 3| = \begin{cases} -(x^3 + 3), & x < -\sqrt[3]{3} \\ x^3 + 3, & x \geq -\sqrt[3]{3}. \end{cases}$$

On the interval $(-\infty, -\sqrt[3]{3})$, $f'(x) = -3x^2$ exists and is never equal to 0; f has no critical numbers on this interval. On the interval $(-\sqrt[3]{3}, \infty)$, $f'(x) = 3x^2$ exists and is equal to 0 when $x = 0$. It follows that 0 is a critical number. At $x = -\sqrt[3]{3}$, the rule for f changes, so it is necessary to investigate the

existence of $f'(-\sqrt[3]{3})$. Now,

$$\begin{aligned}\lim_{x \rightarrow -\sqrt[3]{3}^-} \frac{f(x) - f(-\sqrt[3]{3})}{x - (-\sqrt[3]{3})} &= \lim_{x \rightarrow -\sqrt[3]{3}^-} \frac{-(x^3 + 3) - 0}{x + \sqrt[3]{3}} \\ &= \lim_{x \rightarrow -\sqrt[3]{3}^-} \frac{-(x + \sqrt[3]{3})(x^2 - \sqrt[3]{3}x + \sqrt[3]{9})}{x + \sqrt[3]{3}} \\ &= \lim_{x \rightarrow -\sqrt[3]{3}^-} -(x^2 - \sqrt[3]{3}x + \sqrt[3]{9}) = -3\sqrt[3]{9},\end{aligned}$$

and

$$\begin{aligned}\lim_{x \rightarrow -\sqrt[3]{3}^+} \frac{f(x) - f(-\sqrt[3]{3})}{x - (-\sqrt[3]{3})} &= \lim_{x \rightarrow -\sqrt[3]{3}^+} \frac{(x^3 + 3) - 0}{x + \sqrt[3]{3}} \\ &= \lim_{x \rightarrow -\sqrt[3]{3}^+} \frac{(x + \sqrt[3]{3})(x^2 - \sqrt[3]{3}x + \sqrt[3]{9})}{x + \sqrt[3]{3}} \\ &= \lim_{x \rightarrow -\sqrt[3]{3}^+} (x^2 - \sqrt[3]{3}x + \sqrt[3]{9}) = 3\sqrt[3]{9}.\end{aligned}$$

Because these two one-sided limits are not equal, $f'(x)$ does not exist at $x = -\sqrt[3]{3}$. Therefore, $-\sqrt[3]{3}$ is also a critical number of f .

The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. On the interval $(-\infty, -\sqrt[3]{3})$, $f'(x) = -3x^2 < 0$, while on the intervals $(-\sqrt[3]{3}, 0)$ and $(0, \infty)$, $f'(x) = 3x^2 > 0$. Therefore, f is decreasing on the interval $(-\infty, -\sqrt[3]{3})$ and increasing on the intervals $(-\sqrt[3]{3}, 0)$ and $(0, \infty)$. Since f is continuous on its domain, we can say that f is decreasing on the interval $(-\infty, -\sqrt[3]{3}]$ and is increasing on the interval $[-\sqrt[3]{3}, \infty)$.

36. Let

$$f(x) = |x^2 - 4| = \begin{cases} x^2 - 4, & x \leq -2 \\ -(x^2 - 4), & -2 < x < 2 \\ x^2 - 4, & x \geq 2. \end{cases}$$

On the interval $(-\infty, -2)$, $f'(x) = 2x$ exists and is never equal to 0; f has no critical numbers on this interval. On the interval $(-2, 2)$, $f'(x) = -2x$ exists and is equal to 0 when $x = 0$. It follows that 0 is a critical number. On the interval $(2, \infty)$, $f'(x) = 2x$ exists and is never equal to 0; f has no critical numbers on this interval. At $x = \pm 2$, the rule for f changes, so it is necessary to investigate the existence of $f'(-2)$ and $f'(2)$. Now,

$$\lim_{x \rightarrow -2^-} \frac{f(x) - f(-2)}{x - (-2)} = \lim_{x \rightarrow -2^-} \frac{(x^2 - 4) - 0}{x + 2} = \lim_{x \rightarrow -2^-} \frac{(x - 2)(x + 2)}{x + 2} = \lim_{x \rightarrow -2^-} (x - 2) = -4,$$

and

$$\lim_{x \rightarrow -2^+} \frac{f(x) - f(-2)}{x - (-2)} = \lim_{x \rightarrow -2^+} \frac{-(x^2 - 4) - 0}{x + 2} = \lim_{x \rightarrow -2^+} \frac{-(x - 2)(x + 2)}{x + 2} = \lim_{x \rightarrow -2^+} -(x - 2) = 4.$$

Because these two one-sided limits are not equal, $f'(x)$ does not exist at $x = -2$. Additionally,

$$\lim_{x \rightarrow 2^-} \frac{f(x) - f(2)}{x - 2} = \lim_{x \rightarrow 2^-} \frac{-(x^2 - 4) - 0}{x - 2} = \lim_{x \rightarrow 2^-} \frac{-(x - 2)(x + 2)}{x - 2} = \lim_{x \rightarrow 2^-} -(x + 2) = -4,$$

and

$$\lim_{x \rightarrow 2^+} \frac{f(x) - f(2)}{x - 2} = \lim_{x \rightarrow 2^+} \frac{(x^2 - 4) - 0}{x - 2} = \lim_{x \rightarrow 2^+} \frac{(x - 2)(x + 2)}{x - 2} = \lim_{x \rightarrow 2^+} (x + 2) = 4.$$

Because these two one-sided limits are not equal, $f'(x)$ does not exist at $x = 2$. Therefore, ± 2 are also critical numbers of f .

The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. On the interval $(-\infty, -2)$, $f'(x) = 2x < 0$; on the interval $(-2, 0)$, $f'(x) = -2x > 0$; on the interval $(0, 2)$, $f'(x) = -2x < 0$; finally, on the interval $(2, \infty)$, $f'(x) = 2x > 0$. Therefore, f is decreasing on the intervals $(-\infty, -2)$ and $(0, 2)$ and increasing on the intervals $(-2, 0)$ and $(2, \infty)$. Since f is continuous on its domain, we can say that f is decreasing on the intervals $(-\infty, -2]$ and $[0, 2]$ and increasing on the intervals $[-2, 0]$ and $[2, \infty)$.

37. Let $f(x) = 3 \sin x$. The function f is a constant multiple of the trigonometric function $\sin x$, which is differentiable everywhere; therefore, f is differentiable everywhere. The critical numbers of f therefore occur where $f'(x) = 0$. Now,

$$f'(x) = 3 \cos x,$$

so the critical numbers on the interval $(0, 2\pi)$ are $\frac{\pi}{2}$ and $\frac{3\pi}{2}$. The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. On the interval $(0, \frac{\pi}{2})$, $f'(x) > 0$; on the interval $(\frac{\pi}{2}, \frac{3\pi}{2})$, $f'(x) < 0$; finally, on the interval $(\frac{3\pi}{2}, 2\pi)$, $f'(x) > 0$. Therefore, f is increasing on the intervals $(0, \frac{\pi}{2})$ and $(\frac{3\pi}{2}, 2\pi)$ and decreasing on the interval $(\frac{\pi}{2}, \frac{3\pi}{2})$. Since f is continuous on its domain, we can say that f is

increasing on the intervals $[0, \frac{\pi}{2}]$ and $[\frac{3\pi}{2}, 2\pi]$ and decreasing on the interval $[\frac{\pi}{2}, \frac{3\pi}{2}]$.

38. Let $f(x) = \cos(2x)$. The trigonometric function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = -2 \sin(2x),$$

so the critical numbers on the interval $(0, 2\pi)$ are $\frac{\pi}{2}$, π , and $\frac{3\pi}{2}$. The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. On the interval $(0, \frac{\pi}{2})$, $f'(x) < 0$; on the interval $(\frac{\pi}{2}, \pi)$, $f'(x) > 0$; on the interval $(\pi, \frac{3\pi}{2})$, $f'(x) < 0$; finally, on the interval $(\frac{3\pi}{2}, 2\pi)$, $f'(x) > 0$. Therefore, f is increasing on the intervals $(\frac{\pi}{2}, \pi)$ and $(\frac{3\pi}{2}, 2\pi)$ and decreasing on the intervals $(0, \frac{\pi}{2})$ and $(\pi, \frac{3\pi}{2})$. Since f is

continuous on its domain, we can say that f is increasing on the intervals $[\frac{\pi}{2}, \pi]$ and $[\frac{3\pi}{2}, 2\pi]$ and decreasing on the intervals $[0, \frac{\pi}{2}]$ and $[\pi, \frac{3\pi}{2}]$.

39. Let $f(x) = xe^x$. The function g is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = xe^x + e^x = (x + 1)e^x,$$

so -1 is the only critical number. The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. These inequalities are solved by using the critical number -1 to form two intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $x + 1$	Sign of e^x	Sign of $f'(x)$	Conclusion
$(-\infty, -1)$	$-$	$+$	$-$	f is decreasing
$(-1, \infty)$	$+$	$+$	$+$	f is increasing

Therefore, f is increasing on the interval $(-1, \infty)$ and decreasing on the interval $(-\infty, -1)$. Since f is continuous on its domain, we can say that f is increasing on the interval $[-1, \infty)$ and decreasing on the interval $(-\infty, -1]$.

40. Let $f(x) = x + e^x$. The function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = 1 + e^x,$$

which is never equal to 0 because $e^x > 0$ for all x , so there are no critical numbers. The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. Here, $f'(x) > 1 > 0$ for all x , so f is increasing for all x .

41. Let $f(x) = e^x \sin x$. The function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = e^x \cos x + e^x \sin x = e^x(\sin x + \cos x),$$

so the critical numbers on the interval $(0, 2\pi)$ are $\frac{3\pi}{4}$ and $\frac{7\pi}{4}$. The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. These inequalities are solved by using the critical numbers $\frac{3\pi}{4}$ and $\frac{7\pi}{4}$ to form three intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of e^x	Sign of $\sin x + \cos x$	Sign of $f'(x)$	Conclusion
$(0, \frac{3\pi}{4})$	$+$	$+$	$+$	f is increasing
$(\frac{3\pi}{4}, \frac{7\pi}{4})$	$+$	$-$	$-$	f is decreasing
$(\frac{7\pi}{4}, 2\pi)$	$+$	$+$	$+$	f is increasing

Therefore, f is increasing on the intervals $(0, \frac{3\pi}{4})$ and $(\frac{7\pi}{4}, 2\pi)$ and decreasing on the interval $(\frac{3\pi}{4}, \frac{7\pi}{4})$. Since f is continuous on its domain, we can say that f is

increasing on the intervals $[0, \frac{3\pi}{4}]$ and $[\frac{7\pi}{4}, 2\pi]$ and decreasing on the interval $[\frac{3\pi}{4}, \frac{7\pi}{4}]$.

42. Let $f(x) = e^x \cos x$. The function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = -e^x \sin x + e^x \cos x = e^x(\cos x - \sin x),$$

so the critical numbers on the interval $(0, 2\pi)$ are $\frac{\pi}{4}$ and $\frac{5\pi}{4}$. The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. These inequalities are solved by using the critical numbers $\frac{\pi}{4}$ and $\frac{5\pi}{4}$ to form three intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of e^x	Sign of $\cos x - \sin x$	Sign of $f'(x)$	Conclusion
$(0, \frac{\pi}{4})$	+	+	+	f is increasing
$(\frac{\pi}{4}, \frac{5\pi}{4})$	+	-	-	f is decreasing
$(\frac{5\pi}{4}, 2\pi)$	+	+	+	f is increasing

Therefore, f is increasing on the intervals $(0, \frac{\pi}{4})$ and $(\frac{5\pi}{4}, 2\pi)$ and decreasing on the interval $(\frac{\pi}{4}, \frac{5\pi}{4})$. Since f is continuous on its domain, we can say that f is

increasing on the intervals $[0, \frac{\pi}{4}]$ and $[\frac{5\pi}{4}, 2\pi]$ and decreasing on the interval $[\frac{\pi}{4}, \frac{5\pi}{4}]$.

Applications and Extensions

43. Let $f(x) = 2x^3 - 6x^2 + 6x - 5$. The polynomial function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = 6x^2 - 12x + 6 = 6(x^2 - 2x + 1) = 6(x - 1)^2,$$

so 1 is the only critical number. The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. Because $f'(x) > 0$ for all $x \neq 1$, it follows that f is increasing on the intervals $(-\infty, 1)$ and $(1, \infty)$. Since f is continuous on its domain, we can say that f is increasing for all x .

44. Let $f(x) = x^3 - 3x^2 + 3x$. The polynomial function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = 3x^2 - 6x + 3 = 3(x^2 - 2x + 1) = 3(x - 1)^2,$$

so 1 is the only critical number. The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. Because $f'(x) > 0$ for all $x \neq 1$, it follows that f is increasing on the intervals $(-\infty, 1)$ and $(1, \infty)$. Since f is continuous on its domain, we can say that f is increasing for all x .

45. Let $f(x) = \frac{x}{x+1}$. The rational function f is differentiable on its domain, the set $\{x|x \neq -1\}$, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = \frac{(x+1)(1) - x(1)}{(x+1)^2} = \frac{x+1-x}{(x+1)^2} = \frac{1}{(x+1)^2},$$

so f has no critical numbers. For $x \neq -1$, $f'(x) > 0$, so the Increasing/Decreasing Function Test indicates that f is increasing on the intervals $(-\infty, -1)$ and $(-1, \infty)$; that is, f is increasing on any interval that does not contain $x = -1$.

46. Let $f(x) = \frac{x+1}{x} = 1 + \frac{1}{x}$. The rational function f is differentiable on its domain, the set $\{x|x \neq 0\}$, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = -\frac{1}{x^2},$$

so f has no critical numbers. For $x \neq 0$, $f'(x) < 0$, so the Increasing/Decreasing Function Test indicates that f is decreasing on the intervals $(-\infty, 0)$ and $(0, \infty)$; that is, f is decreasing on any interval that does not contain $x = 0$.

47. Answers will vary. The figure below displays the graph of a function that is continuous on the closed interval $[1, 3]$ but not differentiable on the open interval $(1, 3)$ – the function is not differentiable at $x = 2$ – and for which the conclusion of the Mean Value Theorem does not hold. Note that

$$\frac{f(3) - f(1)}{3 - 1} = \frac{1 - 1}{2} = 0,$$

but the graph of the function does not have a horizontal tangent line anywhere on the open interval $(1, 3)$.

48. Answers will vary. The figure below displays the graph of a function that is differentiable on the open interval $(1, 3)$ but not continuous on the closed interval $[1, 3]$ – the function is not continuous at $x = 1$ – and for which the conclusion of the Mean Value Theorem does not hold. Note that

$$\frac{f(3) - f(1)}{3 - 1} = \frac{1 - 1}{2} = 0,$$

but the graph of the function does not have a horizontal tangent line anywhere on the open interval $(1, 3)$.

49. Let $s(t)$ denote the distance function of the automobile, and assume that this function is differentiable. If the automobile traveled 20 miles at an average speed of 40 mph, the trip took one half hour to complete. Let $t = 0$ denote the beginning of the trip and $t = 0.5$ denote the end of the trip. Because s is continuous on the closed interval $[0, 0.5]$ and differentiable on the open interval $(0, 0.5)$, the conditions of the Mean Value Theorem are satisfied. Therefore, there exists at least one c in $(0, 0.5)$ such that

$$s'(c) = \frac{s(0.5) - s(0)}{0.5 - 0} = \frac{20 - 0}{0.5} = 40 \text{ mph.}$$

Now, s' is the speed of the automobile, so the speed was exactly 40 mph at some time during the trip.

50. Let $v(t)$ denote the speed of the car as indicated by the car's speedometer, where t is measured in hours, and assume that this function is differentiable. Let $t = 0$ correspond to 4:00 p.m. and $t = 0.2$ correspond to 4:12 p.m. Because v is continuous on the closed interval $[0, 0.2]$ and differentiable on the open interval $(0, 0.2)$, the conditions of the Mean Value Theorem are satisfied. Therefore, there exists at least one c in $(0, 0.2)$ such that

$$v'(c) = \frac{v(0.2) - v(0)}{0.2 - 0} = \frac{60 - 40}{0.2} = 100 \text{ mi/h}^2.$$

Now, v' is the acceleration of the automobile, so the acceleration was exactly 100 mi/h^2 at some time between 4:00 p.m. and 4:12 p.m.

51. Let $f(t) = f_2(t) - f_1(t)$, and let $t = 0$ denote the start of the race and $t = T$ denote the end of the race for these two cars. Because the cars start the race together and finish in a tie,

$$f(0) = f_2(0) - f_1(0) = 0 \quad \text{and} \quad f(T) = f_2(T) - f_1(T) = 0.$$

Assuming that f_1 and f_2 are continuous on the closed interval $[0, T]$ and differentiable on the open interval $(0, T)$, the function f will also be continuous on the closed interval $[0, T]$ and differentiable on the open interval $(0, T)$. The Mean Value Theorem therefore applies to f over $[0, T]$, so there is at least one c in $(0, T)$ such that

$$f'(c) = \frac{f(T) - f(0)}{T - 0} = \frac{0 - 0}{T - 0} = 0.$$

Recalling the definition of f , this last statement is equivalent to $f'_2(c) - f'_1(c) = 0$, or $f'_2(c) = f'_1(c)$. Therefore, at some time during the race, the two cars are traveling at the same speed.

52. Assuming f is continuous on the closed interval $[a, b]$ and differentiable on the open interval (a, b) , then the Mean Value Theorem applies and there is at least one c in (a, b) such that

$$f'(c) = \frac{f(b) - f(a)}{b - a} = 0.$$

53. Let $d = -\frac{1}{192}x^4 + \frac{25}{384}x^3 - \frac{25}{128}x^2$ on the closed interval $[0, 5]$.

- (a) The polynomial function d is continuous on the closed interval $[0, 5]$ and differentiable on the open interval $(0, 5)$. Moreover, $d(0) = 0$ and

$$d(5) = -\frac{1}{192}5^4 + \frac{25}{384}5^3 - \frac{25}{128}5^2 = \frac{5^4}{384}(-2 + 5 - 3) = 0.$$

Therefore, d satisfies the conditions of Rolle's Theorem on the interval $[0, 5]$.

- (b) According to part (a), $\boxed{d(0) = d(5) = 0}$, so the deflection at the ends of the beam is always zero; therefore, the ends of the beam must be held fixed in place.
- (c) Differentiating d yields

$$d'(x) = -\frac{1}{48}x^3 + \frac{25}{128}x^2 - \frac{25}{64}x = -\frac{x}{384}(8x^2 - 75x + 150).$$

Therefore, $d'(c) = 0$ when $c = 0$ and when $8c^2 - 75c + 150 = 0$. Applying the quadratic formula to this last equation gives

$$c = \frac{75 \pm \sqrt{(-75)^2 - 4(8)(150)}}{16} = \frac{75 \pm \sqrt{825}}{16} = \frac{75 \pm 5\sqrt{33}}{16}.$$

Now,

$$c = \frac{75 + 5\sqrt{33}}{16} \approx 6.483 \quad \text{and} \quad c = \frac{75 - 5\sqrt{33}}{16} \approx 2.892,$$

so the only c in $(0, 5)$ that satisfies the conclusion of Rolle's Theorem is $c = \frac{75 - 5\sqrt{33}}{16} \approx 2.892$ ft.

Using the computer algebra system *Maple*,

$$d\left(\frac{75 - 5\sqrt{33}}{16}\right) = -\frac{24375 + 34375\sqrt{33}}{524288} \text{ ft} \approx -0.423 \text{ ft}.$$

(d) The figure below displays the graph of d on the interval $[0, 5]$.

54. Let $f(x) = x^4 - 2x^3 - 4x^2 + 7x + 3$.

- (a) The polynomial function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now, $f'(x) = 4x^3 - 6x^2 - 8x + 7$. Using the computer algebra system *Maple*, the zeros of $f'(x)$ are found to be -1.243 , 0.684 , and 2.059 , rounded to three decimal places. It follows that the critical numbers of f are approximately -1.243 , 0.684 , and 2.059 .
- (b) The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. The critical numbers of f divide the number line into four intervals: $(-\infty, -1.243)$, $(-1.243, 0.684)$, $(0.684, 2.059)$, and $(2.059, \infty)$. Select a test number in each interval and evaluate f' at that number. If $f'(x) < 0$ at the test number, then $f'(x) < 0$ throughout the interval; if $f'(x) > 0$ at the test number, then $f'(x) > 0$ throughout the interval. The following table summarizes the results:

Interval	Test Number	Value of $f'(x)$ at Test Number	Sign of $f'(x)$	Conclusion
$(-\infty, -1.243)$	-2	-33	$-$	f is decreasing
$(-1.243, 0.684)$	0	7	$+$	f is increasing
$(0.684, 2.059)$	1	-3	$-$	f is decreasing
$(2.059, \infty)$	3	37	$+$	f is increasing

Therefore, f is increasing on the intervals $(-1.243, 0.684)$ and $(2.059, \infty)$ and decreasing on the intervals $(-\infty, -1.243)$ and $(0.684, 2.059)$. Since f is continuous on its domain, we can say that f is

increasing on the intervals $[-1.243, 0.684]$ and $[2.059, \infty)$

and

decreasing on the intervals $(-\infty, -1.243]$ and $[0.684, 2.059]$.

55. Let $f(x) = (x-1)\sin x$. The function f is continuous and differentiable everywhere, so it is continuous on the closed interval $[0, 1]$ and differentiable on the open interval $(0, 1)$. Additionally, $f(0) = (-1)\sin 0 = 0$, and $f(1) = (0)\sin 1 = 0$, so $f(0) = f(1)$, and all three conditions of Rolle's Theorem are satisfied. Therefore, there exists at least one c in $(0, 1)$ such that $f'(c) = 0$. Now,

$$f'(x) = (x-1)\cos x + \sin x,$$

so

$$(c-1)\cos c + \sin c = 0.$$

Because $c \in (0, 1)$, $\cos c \neq 0$, so the previous equation can be divided by $\cos c$ to yield

$$c - 1 + \tan c = 0 \quad \text{or} \quad \tan c + c = 1.$$

In conclusion, the equation $\tan x + x = 1$ has a solution in the interval $(0, 1)$.

56. Let $f(x) = x^3 - 2$. Then $f(\sqrt[3]{2}) = (\sqrt[3]{2})^3 - 2 = 2 - 2 = 0$, so $\sqrt[3]{2}$ is a real zero of f . Now, if $x \leq 0$, then $x^3 \leq 0$ and $x^3 - 2 \leq -2 < 0$; consequently, if f does have another real zero, that other real zero must be a positive number. Suppose, for the sake of contradiction, that f does have another real zero at $z > 0$. The polynomial function f is continuous and differentiable everywhere, so it is continuous on the closed interval between z and $\sqrt[3]{2}$ and differentiable on the open interval between z and $\sqrt[3]{2}$. Additionally, $f(z) = f(\sqrt[3]{2}) = 0$, so Rolle's Theorem applies and there must exist a c between z and $\sqrt[3]{2}$ such that $f'(c) = 0$. However, $f'(x) = 3x^2 = 0$ only for $x = 0$ which is not between the positive numbers z and $\sqrt[3]{2}$. Therefore, f has exactly one real zero.

57. Let $f(x) = (x-8)^3$. Then $f(8) = (8-8)^3 = 0$, so 8 is a real zero of f . Suppose, for the sake of contradiction, that f does have another real zero at z . The polynomial function f is continuous and differentiable everywhere, so it is continuous on the closed interval between z and 8 and differentiable on the open interval between z and 8. Additionally, $f(z) = f(8) = 0$, so Rolle's Theorem applies and there must exist a c between z and 8 such that $f'(c) = 0$. However, $f'(x) = 3(x-8)^2 = 0$ only for $x = 8$ which is not between the positive numbers z and 8. Therefore, f has exactly one real zero.

58. Let $f(x) = (x^2 - 4x + 3)(x^2 + x + 1)$. The function f is continuous and differentiable everywhere, so it is continuous on the closed interval $[1, 3]$ and differentiable on the open interval $(1, 3)$. Additionally,

$$f(1) = (1 - 4 + 3)(1 + 1 + 1) = 0(3) = 0$$

and

$$f(3) = (9 - 12 + 3)(9 + 3 + 1) = 0(13) = 0,$$

so $f(1) = f(3)$ and Rolle's Theorem applies. Therefore, there must exist at least one c between 1 and 3 such that $f'(c) = 0$. To verify this directly, note that

$$\begin{aligned} f'(x) &= (x^2 - 4x + 3)(2x + 1) + (x^2 + x + 1)(2x - 4) \\ &= 2x^3 - 8x^2 + 6x + x^2 - 4x + 3 + 2x^3 + 2x^2 + 2x - 4x^2 - 4x - 4 \\ &= 4x^3 - 9x^2 - 1. \end{aligned}$$

This polynomial function is continuous everywhere, so it is continuous on the closed interval $[1, 3]$, and $f'(1) = 4 - 9 - 1 = -6 < 0$ and $f'(3) = 108 - 81 - 1 = 26 > 0$. The Intermediate Value Theorem then guarantees there exists a number c between 1 and 3 such that $f'(c) = 0$.

59. Though the function $f(x) = |x|$ is continuous on the closed interval $[-1, 1]$, it is not differentiable on the open interval $(-1, 1)$ because $f'(x)$ does not exist at $x = 0$. Therefore, Rolle's Theorem does not apply to f on the interval $[-1, 1]$.

60. Let $f(x) = x^{2/3}$. Then

$$\frac{f(1) - f(-1)}{1 - (-1)} = \frac{1 - 1}{2} = 0;$$

however, $f'(x) = \frac{2}{3}x^{-1/3}$, which is never equal to zero. Therefore, there is no c in $[-1, 1]$ for which

$$f'(c) = \frac{f(1) - f(-1)}{1 - (-1)}.$$

Though f is continuous on the closed interval $[-1, 1]$, it is not differentiable on the open interval $(-1, 1)$ because $f'(x)$ does not exist at $x = 0$. Therefore, the Mean Value Theorem does not apply to f on the interval $[-1, 1]$.

61. Let $f(x) = \sin^{-1} x$. Then

$$f(1) - f(0) = \sin^{-1} 1 - \sin^{-1} 0 = \frac{\pi}{2} - 0 = \frac{\pi}{2},$$

and $f'(x) = \frac{1}{\sqrt{1-x^2}}$. Therefore,

$$f'(N) = \frac{1}{\sqrt{1-N^2}} = \frac{\pi}{2}$$

when

$$\begin{aligned} \sqrt{1-N^2} &= \frac{2}{\pi} \\ 1-N^2 &= \frac{4}{\pi^2} \\ N^2 &= 1 - \frac{4}{\pi^2} \\ N &= \pm \sqrt{1 - \frac{4}{\pi^2}}. \end{aligned}$$

Of these numbers, $N = \sqrt{1 - \frac{4}{\pi^2}}$ is contained in the interval $(0, 1)$.

62. Let $f(x) = Ax^2 + Bx + C$. The polynomial function f is continuous and differentiable everywhere, so it is continuous on the closed interval $[a, b]$ and differentiable on the open interval (a, b) for any real numbers a and b with $a < b$. The Mean Value Theorem applies and guarantees there exists a c in (a, b) such that

$$f'(c) = \frac{f(b) - f(a)}{b - a}.$$

Now,

$$\begin{aligned} \frac{f(b) - f(a)}{b - a} &= \frac{(Ab^2 + Bb + C) - (Aa^2 + Ba + C)}{b - a} \\ &= \frac{A(b^2 - a^2) + B(b - a)}{b - a} = A(b + a) + B, \end{aligned}$$

and

$$f'(x) = 2Ax + B.$$

Therefore,

$$f'(c) = \frac{f(b) - f(a)}{b - a} \quad \text{when} \quad 2Ac + B = A(b + a) + B,$$

or $c = \frac{b+a}{2}$, the midpoint of the interval $[a, b]$.

63. (a) Let $f(x) = \sqrt{x}$. The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. Now,

$$f'(x) = \frac{1}{2}x^{-1/2} = \frac{1}{2\sqrt{x}} > 0$$

for $x > 0$, so $\boxed{f \text{ is increasing on the interval } (0, \infty)}$.

- (b) Because f is increasing on the interval $(0, \infty)$ and is continuous for $x \geq 0$, $\boxed{f \text{ is increasing for all } x \geq 0}$; that is, f is increasing on its domain.
64. Consider the function $g(x) = \frac{a}{5}x^5 + \frac{b}{4}x^4 + \frac{c}{3}x^3 + \frac{d}{2}x^2 + ex$ and suppose that $\frac{a}{5} + \frac{b}{4} + \frac{c}{3} + \frac{d}{2} + e = 0$. The polynomial function g is continuous and differentiable everywhere, so it is continuous on the closed interval $[0, 1]$ and differentiable on the open interval $(0, 1)$. Additionally,

$$g(0) = 0 \quad \text{and} \quad g(1) = \frac{a}{5} + \frac{b}{4} + \frac{c}{3} + \frac{d}{2} + e = 0,$$

so $g(0) = g(1)$, and Rolle's Theorem applies. Therefore, there exists at least one c in $(0, 1)$ such that $g'(c) = 0$. But

$$g'(x) = ax^4 + bx^3 + cx^2 + dx + e = f(x).$$

In conclusion, the function $f(x) = ax^4 + bx^3 + cx^2 + dx + e$ must have a zero between 0 and 1 if $\frac{a}{5} + \frac{b}{4} + \frac{c}{3} + \frac{d}{2} + e = 0$.

65. (a) $\boxed{\text{Not necessarily true}}$. Let $f(x) = e^x$ and $g(x) = -1$. Then $f'(x) = e^x$ and $g'(x) = 0$ exist and $f'(x) > g'(x)$ for all real x ; however, the graphs of $y = f(x)$ and $y = g(x)$ never intersect because $f(x) > 0$ for all real x .
- (b) $\boxed{\text{True}}$. Suppose for sake of contradiction that the graphs of $y = f(x)$ and $y = g(x)$ intersect more than once. In particular, suppose the graphs intersect at a and b with $a < b$. Consider the function $h(x) = f(x) - g(x)$. The functions f and g are continuous and differentiable everywhere, so the function h is also continuous and differentiable everywhere. Additionally,

$$h(a) = f(a) - g(a) = 0 \quad \text{and} \quad h(b) = f(b) - g(b) = 0,$$

so $h(a) = h(b)$, and Rolle's Theorem applies. It follows that there exists at least one c in (a, b) such that $h'(c) = f'(c) - g'(c) = 0$; equivalently, $f'(c) = g'(c)$, in violation of the condition that $f'(x) > g'(x)$ for all real x . Therefore, the graphs of $y = f(x)$ and $y = g(x)$ can intersect no more than once.

- (c) $\boxed{\text{Not necessarily true}}$. Let $f(x) = 2x$ and $g(x) = x$. Then $f'(x) = 2$ and $g'(x) = 1$ exist and $f'(x) > g'(x)$ for all real x ; however, the graphs of $y = f(x)$ and $y = g(x)$ intersect at the origin.
- (d) $\boxed{\text{False}}$. See the proof for part (b).
- (e) $\boxed{\text{False}}$. Even if the graphs intersect, the tangent lines will be different because the condition $f'(x) > g'(x)$ guarantees that the tangent lines will have different slopes.

66. Suppose, for sake of contradiction, that there exists a number k for which the function $f(x) = x^3 - 3x + k$ has two distinct zeros in the interval $[0, 1]$. Let x_1 and x_2 denote the two zeros, with $x_1 < x_2$. The polynomial function f is continuous and differentiable everywhere, so it is continuous on the closed interval $[x_1, x_2]$ and differentiable on the open interval (x_1, x_2) . Additionally $f(x_1) = f(x_2) = 0$, so Rolle's Theorem applies. It follows that there exists a number c in $(x_1, x_2) \subset (0, 1)$ such that $f'(c) = 0$. However, $f'(x) = 3x^2 - 3 = 3(x - 1)(x + 1)$ which is never equal to zero in $(0, 1)$. Therefore, there is no k for which the function $f(x) = x^3 - 3x + k$ has two distinct zeros in the interval $[0, 1]$.

67. Consider the function $f(x) = \frac{e^x}{x^2}$ for $x > 0$. Now,

$$f'(x) = \frac{x^2 e^x - e^x(2x)}{x^4} = \frac{e^x(x-2)}{x^3},$$

so the only critical number on $x > 0$ is 2. The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. These inequalities are solved by using the critical number 2 to form two intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of e^x	Sign of $x-2$	Sign of x^3	Sign of $f'(x)$	Conclusion
$(0, 2)$	+	-	+	-	f is decreasing
$(2, \infty)$	+	+	+	+	f is increasing

Because f is decreasing on the interval $(0, 2)$ and increasing on the interval $(2, \infty)$, f must have an absolute minimum at 2. Therefore,

$$f(x) = \frac{e^x}{x^2} \geq f(2) = \frac{e^2}{4} \approx 1.847 > 1,$$

so that, for $x > 0$

$$\frac{e^x}{x^2} > 1 \quad \text{or} \quad e^x > x^2.$$

68. Consider the function $f(x) = e^x - 1 - x$ for $x > 0$. Now, $f'(x) = e^x - 1$. Because $e^x > 1$ for $x > 0$, it follows that $f'(x) > 0$ for $x > 0$. Therefore, by the Increasing/Decreasing Function Test, f is increasing for $x > 0$, so that $f(x) > f(0) = 1 - 1 - 0 = 0$. Therefore, for $x > 0$

$$f(x) = e^x - 1 - x > 0 \quad \text{or} \quad e^x > 1 + x.$$

69. For $x > 1$, $\ln x > 0$. Next, consider the function $f(x) = x - \ln x$ for $x > 1$. Now, $f'(x) = 1 - \frac{1}{x}$. For $x > 1$

$$\frac{1}{x} < 1 \quad \text{so that} \quad 1 - \frac{1}{x} > 0;$$

that is, $f'(x) > 0$. Therefore, by the Increasing/Decreasing Function Test, f is increasing for $x > 1$, so that $f(x) > f(1) = 1 - \ln 1 = 1 > 0$. Therefore, for $x > 1$

$$f(x) = x - \ln x > 0 \quad \text{or} \quad x > \ln x.$$

70. Consider the function $f(\theta) = \tan \theta - \theta$ on the interval $\left(0, \frac{\pi}{2}\right)$. Now, $f'(\theta) = \sec^2 \theta - 1$. On the interval $\left(0, \frac{\pi}{2}\right)$, $\sec^2 \theta > 1$, so $f'(\theta) > 0$. Therefore, by the Increasing/Decreasing Function Test, f is increasing on the interval $\left(0, \frac{\pi}{2}\right)$, so that $f(\theta) > f(0) = \tan 0 - 0 = 0$. Therefore, on the interval $\left(0, \frac{\pi}{2}\right)$,

$$\tan \theta - \theta > 0 \quad \text{or} \quad \tan \theta > \theta.$$

71. Let f be a function that is continuous on the closed interval $[a, b]$ and differentiable on the open interval (a, b) . Further, suppose that $f(x) = 0$ for three different numbers in (a, b) . Let x_1 , x_2 , and x_3 denote the three zeros with $x_1 < x_2 < x_3$. Consider the interval $[x_1, x_2]$. Because $[x_1, x_2]$ is contained in $[a, b]$, f is continuous on the closed interval $[x_1, x_2]$ and differentiable on the open interval (x_1, x_2) . Additionally, $f(x_1) = f(x_2) = 0$, so Rolle's Theorem applies and there exists at least one number c_1 in (x_1, x_2) such that $f'(c_1) = 0$. Next, consider the interval $[x_2, x_3]$. Because $[x_2, x_3]$ is contained in $[a, b]$, f is continuous on the closed interval $[x_2, x_3]$ and differentiable on the open interval (x_2, x_3) . Additionally, $f(x_2) = f(x_3) = 0$, so Rolle's Theorem applies and there exists at least one number c_2 in (x_2, x_3) such that $f'(c_2) = 0$. By construction, $c_1 < x_2$ and $c_2 > x_2$, so c_1 cannot be equal to c_2 . Therefore, there are at least two numbers in (a, b) at which $f'(x) = 0$.

72. Because f is differentiable on (a, b) , it is continuous on (a, b) . To show that f is decreasing on (a, b) , choose two numbers x_1 and x_2 in (a, b) with $x_1 < x_2$. With x_1 and x_2 in (a, b) , it follows that f is continuous on $[x_1, x_2]$ and differentiable on (x_1, x_2) , and the Mean Value Theorem applies. It follows that there exists a number c in (x_1, x_2) for which

$$f'(c) = \frac{f(x_2) - f(x_1)}{x_2 - x_1}.$$

Because $f'(x) < 0$ for all x in (a, b) , it follows that $f'(c) < 0$. With $x_1 < x_2$, $x_2 - x_1 > 0$, so

$$f(x_2) - f(x_1) < 0 \quad \text{or} \quad f(x_2) < f(x_1).$$

Therefore, f is decreasing on (a, b) .

73. Suppose, for sake of contradiction, that f has an absolute extreme value on (a, b) , say at c . Because c is in (a, b) – and, in particular, not at an endpoint of the interval – $f(c)$ must also be a local extreme value. Now, local extreme values can only occur at critical numbers. It follows that $f'(c)$ must be equal to zero or not exist. However, $f'(x)$ exists and is never equal to 0 for x in (a, b) . Therefore, f cannot have an extreme value on (a, b) .

Challenge Problems

74. Let f be a polynomial function with real zeros x_1 and x_2 , $x_1 < x_2$. Because f is continuous and differentiable everywhere, it is continuous on the closed interval $[x_1, x_2]$ and differentiable on the open interval (x_1, x_2) . Additionally, $f(x_1) = f(x_2) = 0$, so Rolle's Theorem applies. It follows that there exists at least one number c in (x_1, x_2) such that $f'(c) = 0$. Therefore, between any two real zeros of the polynomial function f , there is a real zero of its derivative f' .
75. Let a , b , c , and d be real numbers and consider the function $f(x) = ax^3 + bx^2 + cx + d$. This polynomial function is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = 3ax^2 + 2bx + c.$$

The discriminant of this quadratic function is $(2b)^2 - 4(3a)(c) = 4(b^2 - 3ac)$. Consider the following cases:

- Case I: $b^2 - 3ac < 0$: In this case, $f'(x)$ is never equal to zero and is always positive when $a > 0$ and always negative when $a < 0$. Therefore, f is increasing for all x when $a > 0$ and decreasing for all x when $a < 0$.
- Case II: $b^2 - 3ac = 0$: In this case, $f'(x) = 0$ when $x = -\frac{b}{3a}$. For all other x , $f'(x) > 0$ when $a > 0$ and $f'(x) < 0$ when $a < 0$. Therefore, f is increasing for all $x \neq -\frac{b}{3a}$ when $a > 0$ and decreasing for all $x \neq -\frac{b}{3a}$ when $a < 0$. Because f is continuous on its domain, we can say f is increasing for all x when $a > 0$ and decreasing for all x when $a < 0$.
- Case III: $b^2 - 3ac > 0$: In this case, $f'(x) = 0$ when

$$x = \frac{-b \pm \sqrt{b^2 - 3ac}}{3a}.$$

For notation, let

$$x_1 = \min \left(\frac{-b \pm \sqrt{b^2 - 3ac}}{3a} \right) \quad \text{and} \quad x_2 = \max \left(\frac{-b \pm \sqrt{b^2 - 3ac}}{3a} \right).$$

If $a > 0$, then $f'(x) > 0$ and f is increasing on the intervals $(-\infty, x_1)$ and (x_2, ∞) and $f'(x) < 0$ and f is decreasing on the interval (x_1, x_2) . If $a < 0$, then $f'(x) > 0$ and f is increasing on the interval (x_1, x_2) and $f'(x) < 0$ and f is decreasing on the intervals $(-\infty, x_1)$ and (x_2, ∞) .

76. Let $f(x) = x^n + ax + b$, where n is a positive even integer. Suppose, for sake of contradiction, that f has more than two distinct real zeros. Let x_1, x_2 , and x_3 , with $x_1 < x_2 < x_3$, denote three of the distinct real zeros of f . Consider the interval $[x_1, x_2]$. The polynomial function f is continuous and differentiable everywhere, so it is continuous on the closed interval $[x_1, x_2]$ and differentiable on the open interval (x_1, x_2) . Additionally, $f(x_1) = f(x_2) = 0$, so Rolle's Theorem applies and there exists at least one number c_1 in (x_1, x_2) such that $f'(c_1) = 0$. Next, consider the interval $[x_2, x_3]$. Following the same reasoning as above, f is continuous on the closed interval $[x_2, x_3]$ and differentiable on the open interval (x_2, x_3) . Additionally, $f(x_2) = f(x_3) = 0$, so Rolle's Theorem applies and there exists at least one number c_2 in (x_2, x_3) such that $f'(c_2) = 0$. It follows that there are at least two distinct numbers in (a, b) at which $f'(x) = 0$. However, $f'(x) = nx^{n-1} + a$, which has only one real zero because n is an even integer, so $n - 1$ is an odd integer. Therefore, the function $f(x) = x^n + ax + b$, where n is a positive even integer, has at most two distinct real zeros.
77. Let $f(x) = x^n + ax + b$, where n is a positive odd integer. Suppose, for sake of contradiction, that f has more than three distinct real zeros. Let x_1, x_2, x_3 , and x_4 , with $x_1 < x_2 < x_3 < x_4$, denote four of the distinct real zeros of f . Consider the interval $[x_1, x_2]$. The polynomial function f is continuous and differentiable everywhere, so it is continuous on the closed interval $[x_1, x_2]$ and differentiable on the open interval (x_1, x_2) . Additionally, $f(x_1) = f(x_2) = 0$, so Rolle's Theorem applies and there exists at least one number c_1 in (x_1, x_2) such that $f'(c_1) = 0$. Next, consider the interval $[x_2, x_3]$. Following the same reasoning as above, f is continuous on the closed interval $[x_2, x_3]$ and differentiable on the open interval (x_2, x_3) . Additionally, $f(x_2) = f(x_3) = 0$, so Rolle's Theorem applies and there exists at least one number c_2 in (x_2, x_3) such that $f'(c_2) = 0$. Finally, consider the interval $[x_3, x_4]$. Following the same reasoning as above, f is continuous on the closed interval $[x_3, x_4]$ and differentiable on the open interval (x_3, x_4) . Additionally, $f(x_3) = f(x_4) = 0$, so Rolle's Theorem applies and there exists at least one number c_3 in (x_3, x_4) such that $f'(c_3) = 0$. It follows that there are at least three distinct numbers in (a, b) at which $f'(x) = 0$. However, $f'(x) = nx^{n-1} + a$, which has only at most two distinct real zeros because n is an odd integer, so $n - 1$ is an even integer. Therefore, the function $f(x) = x^n + ax + b$, where n is a positive odd integer, has at most three distinct real zeros.
78. Let $f(x) = x^n + ax^2 + b$, where n is a positive odd integer. Suppose, for sake of contradiction, that f has more than three distinct real zeros. Let x_1, x_2, x_3 , and x_4 , with $x_1 < x_2 < x_3 < x_4$, denote four of the distinct real zeros of f . Consider the interval $[x_1, x_2]$. The polynomial function f is continuous and differentiable everywhere, so it is continuous on the closed interval $[x_1, x_2]$ and differentiable on the open interval (x_1, x_2) . Additionally, $f(x_1) = f(x_2) = 0$, so Rolle's Theorem applies and there exists at least one number c_1 in (x_1, x_2) such that $f'(c_1) = 0$. By similar reasoning, there exists at least one number c_2 in (x_2, x_3) and at least one number c_3 in (x_3, x_4) such that $f'(c_2) = f'(c_3) = 0$. However, $f'(x) = nx^{n-1} + 2ax = x(nx^{n-2} + 2a)$, which has only two distinct real zeros because n is an odd integer, so $n - 2$ is also an odd integer. Therefore, the function $f(x) = x^n + ax^2 + b$, where n is a positive odd integer, has at most three distinct real zeros.
79. Let $f(x) = x^n + ax^2 + b$, where n is a positive even integer. Suppose, for sake of contradiction, that f has more than four distinct real zeros. Let x_1, x_2, x_3, x_4 , and x_5 , with $x_1 < x_2 < x_3 < x_4 < x_5$, denote five of the distinct real zeros of f . Consider the interval $[x_1, x_2]$. The polynomial function f is continuous and differentiable everywhere, so it is continuous on the closed interval $[x_1, x_2]$ and differentiable on the open interval (x_1, x_2) . Additionally, $f(x_1) = f(x_2) = 0$, so Rolle's Theorem applies and there exists at least one number c_1 in (x_1, x_2) such that $f'(c_1) = 0$. By similar reasoning, there exists at least one number c_2 in (x_2, x_3) , at least one number c_3 in (x_3, x_4) , and at least one number c_4 in (x_4, x_5) such that $f'(c_2) = f'(c_3) = f'(c_4) = 0$. However, $f'(x) = nx^{n-1} + 2ax = x(nx^{n-2} + 2a)$, which has at most three distinct real zeros because n is an even integer, so $n - 2$ is also an even integer. Therefore, the function $f(x) = x^n + ax^2 + b$, where n is a positive even integer, has at most four distinct real zeros.
80. Consider the function $f(x) = \sqrt{x}$ on the interval $[64, 66]$. Because f is continuous on $[0, \infty)$ and differentiable on $(0, \infty)$, it is continuous on the closed interval $[64, 66]$ and differentiable on the open interval $(64, 66)$. By the Mean Value Theorem, there exists a number c in $(64, 66)$ for which

$$f'(c) = \frac{f(66) - f(64)}{66 - 64} = \frac{\sqrt{66} - \sqrt{64}}{2} = \frac{\sqrt{66} - 8}{2}.$$

Now,

$$f'(x) = \frac{1}{2\sqrt{x}} \quad \text{so} \quad f'(c) = \frac{1}{2\sqrt{c}}.$$

With $64 < c < 66$, it follows that $8 < \sqrt{c} < \sqrt{66}$ and $16 < 2\sqrt{c} < 2\sqrt{66}$ so that

$$\frac{1}{2\sqrt{66}} < \frac{1}{2\sqrt{c}} = f'(c) < \frac{1}{16}.$$

Substituting for $f'(c)$ from the Mean Value Theorem gives

$$\frac{1}{2\sqrt{66}} < \frac{\sqrt{66} - 8}{2} < \frac{1}{16}.$$

Multiplying this compound inequality by 2 and noting that

$$\frac{1}{9} = \frac{1}{\sqrt{81}} < \frac{1}{\sqrt{66}},$$

then yields

$$\frac{1}{9} < \sqrt{66} - 8 < \frac{1}{8}.$$

81. Let a , b , c , and d be real numbers with $ad - bc \neq 0$. Additionally, let $n \geq 2$ be an integer. Consider the function $f(x) = \frac{ax^n + b}{cx^n + d}$. The rational function f is differentiable on its domain, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$\begin{aligned} f'(x) &= \frac{(cx^n + d)(anx^{n-1}) - (ax^n + b)(cnx^{n-1})}{(cx^n + d)^2} \\ &= \frac{acnx^{2n-1} + adnx^{n-1} - acnx^{2n-1} - bcnx^{n-1}}{(cx^n + d)^2} = \frac{(ad - bc)nx^{n-1}}{(cx^n + d)^2}, \end{aligned}$$

so 0 is the only critical number. Suppose that n is odd, so that $n - 1$ is even. If $ad - bc > 0$, then $f'(x) > 0$ and f is increasing everywhere on the domain of f except at $x = 0$. Because f is continuous on its domain, we can say that f is increasing on its domain. If $ad - bc < 0$, then $f'(x) < 0$ and f is decreasing everywhere on the domain of f except at $x = 0$. Because f is continuous on its domain, we can say that f is decreasing on its domain. On the other hand, suppose that n is even, so that $n - 1$ is odd. If $ad - bc > 0$, then $f'(x) > 0$ and f is increasing on that portion of the domain of f where $x > 0$, while $f'(x) < 0$ and f is decreasing on that portion of the domain of f where $x < 0$. If $ad - bc < 0$, then $f'(x) < 0$ and f is decreasing on that portion of the domain of f where $x < 0$, while $f'(x) > 0$ and f is increasing on that portion of the domain of f where $x > 0$.

82. Let $f(x) = -x + \ln(1 + x)^{1+x} = -x + (1 + x)\ln(1 + x)$. The domain of this function is the set $\{x | x > -1\}$. Now,

$$f'(x) = -1 + (1 + x) \cdot \frac{1}{1 + x} + \ln(1 + x) = -1 + 1 + \ln(1 + x) = \ln(1 + x),$$

so the only critical number is 0. The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. For $-1 < x < 0$, $0 < 1 + x < 1$, so $f'(x) = \ln(1 + x) < 0$; on the other hand, for $x > 0$, $1 + x > 1$ and $f'(x) = \ln(1 + x) > 0$. Therefore, f is decreasing on the interval $(-1, 0)$ and increasing on the interval $(0, \infty)$, so that f must have an absolute minimum at 0. Therefore,

$$f(x) = -x + \ln(1 + x)^{1+x} \geq f(0) = -0 + \ln 1^1 = 0,$$

so that, for $x > -1$

$$-x + \ln(1 + x)^{1+x} \geq 0 \quad \text{or} \quad \ln(1 + x)^{1+x} \geq x.$$

83. Let a and b be real numbers with $0 < a < b$ and consider the function $f(x) = \ln x$ on the interval $[a, b]$. The natural logarithm function is continuous and differentiable on its domain, so it is continuous on the closed interval $[a, b]$ and differentiable on the open interval (a, b) . By the Mean Value Theorem, there exists a number c in (a, b) for which

$$f'(c) = \frac{f(b) - f(a)}{b - a} = \frac{\ln b - \ln a}{b - a} = \frac{1}{b - a} \ln \frac{b}{a}.$$

Now,

$$f'(x) = \frac{1}{x} \quad \text{so} \quad f'(c) = \frac{1}{c}.$$

With $a < c < b$, it follows that

$$\frac{1}{b} < \frac{1}{c} = f'(c) < \frac{1}{a},$$

so, substituting for $f'(c)$ from the Mean Value Theorem,

$$\frac{1}{b} < \frac{1}{b - a} \ln \frac{b}{a} < \frac{1}{a}.$$

Taking the reciprocal of each component of this compound inequality and then multiplying by $\ln(b/a)$, which is positive because $b > a$ so that $b/a > 1$, yields

$$a \ln \frac{b}{a} < b - a < b \ln \frac{b}{a}.$$

84. Let n be a positive integer and consider the function $f(x) = \ln x$ on the interval $[n, n + 1]$. The natural logarithm function is continuous and differentiable on its domain, so it is continuous on the closed interval $[n, n + 1]$ and differentiable on the open interval $(n, n + 1)$. By the Mean Value Theorem, there exists a number c in $(n, n + 1)$ for which

$$f'(c) = \frac{f(n + 1) - f(n)}{(n + 1) - n} = \frac{\ln(n + 1) - \ln n}{1} = \ln \left(\frac{n + 1}{n} \right) = \ln \left(1 + \frac{1}{n} \right).$$

Now,

$$f'(x) = \frac{1}{x} \quad \text{so} \quad f'(c) = \frac{1}{c}.$$

With $n < c < n + 1$, it follows that

$$\frac{1}{n + 1} < \frac{1}{c} = f'(c) < \frac{1}{n},$$

so, substituting for $f'(c)$ from the Mean Value Theorem,

$$\frac{1}{n + 1} < \ln \left(1 + \frac{1}{n} \right) < \frac{1}{n}.$$

Multiplying this compound inequality by n then yields

$$\frac{n}{n + 1} < n \ln \left(1 + \frac{1}{n} \right) < 1 \quad \text{or} \quad \frac{n}{n + 1} < \ln \left(1 + \frac{1}{n} \right)^n < 1.$$

4.4: Local Extrema and Concavity

Concepts and Vocabulary

1. **False**. If a function f is continuous on the interval $[a, b]$, differentiable on the interval (a, b) , and changes from an increasing function to a decreasing function at the point $(c, f(c))$, then $f(c)$ is a **local maximum value of f** .
2. **False**. Suppose c is a critical number of f and (a, b) is an open interval containing c . If $f'(x)$ is positive on both sides of c , then $f(c)$ is **neither a local maximum value nor a local minimum value** of f .
3. Suppose a function f is continuous on a closed interval $[a, b]$ and differentiable on the open interval (a, b) . If the graph of f lies above each of its tangent lines on the interval (a, b) , then f is **(a) concave up** on (a, b) .
4. If the acceleration of an object in rectilinear motion is negative, then the velocity of the object is **(b) decreasing**.
5. Suppose f is a function that is differentiable on an open interval containing c and the concavity of f changes at the point $(c, f(c))$. Then $(c, f(c))$ is an **(a) inflection point** of f .
6. Suppose a function f is continuous on a closed interval $[a, b]$ and both f' and f'' exist on the open interval (a, b) . If $f''(x) > 0$ on the interval (a, b) , then f is **(c) concave up** on (a, b) .
7. **True**. Suppose f is a function for which f' and f'' exist on an open interval (a, b) and suppose c , $a < c < b$, is a critical number of f . If $f''(c) = 0$, then the Second Derivative Test cannot be used to determine if there is a local extremum at c .
8. **False**. Suppose a function f is differentiable on the open interval (a, b) . If either $f''(c) = 0$ or f'' does not exist at the number c in (a, b) , then $(c, f(c))$ is a **candidate** for an inflection point of f . The point $(c, f(c))$ will be an inflection point if concavity changes at c .

Skill Building

9. (a) Based on the graph of f , f has
 - a **local maximum value at the point $(-1, 0)$** ,
 - a **local minimum value at the points $(-2.5, -4)$ and $(0.5, -4)$** , and
 - a **point of inflection at the points $(-1.8, -2)$ and $(-0.2, -2)$** .
 (b) Based on the graph of f , f is increasing on the intervals $(-2.5, -1)$ and $(0.5, \infty)$ and decreasing on the intervals $(-\infty, -2.5)$ and $(-1, 0.5)$. Since f is continuous on its domain, we can say that f is
 - **increasing on the intervals $[-2.5, -1]$ and $[0.5, \infty)$** and
 - **decreasing on the intervals $(-\infty, -2.5]$ and $[-1, 0.5]$** .
 Additionally, f is
 - **concave up on the intervals $(-\infty, -1.8)$ and $(-0.2, \infty)$** , and
 - **concave down on the interval $(-1.8, -0.2)$** .
10. (a) Based on the graph of f , f has

- a local maximum value at the points $(-1, 2)$ and $(7, 7)$,
 - a local minimum value at the point $(2, -6)$, and
 - a point of inflection at the points $(0, -2)$ and $(4, 0)$.
- (b) Based on the graph of f , f is increasing on the intervals $(-4, -1)$ and $(2, 7)$ and decreasing on the intervals $(-1, 2)$ and $(7, 10)$. Since f is continuous on its domain, we can say that f is
- increasing on the intervals $[-4, -1]$ and $[2, 7]$ and
 - decreasing on the intervals $[-1, 2]$ and $[7, 10]$.

Additionally, f is

- concave up on the interval $(0, 4)$, and
 - concave down on the intervals $(-4, 0)$ and $(4, 10)$.
11. (a) Based on the graph of f , f has
- a local maximum value at the points $(-2, 3)$ and $(12, 10)$,
 - a local minimum value at the point $(0, 0)$, and
 - no points of inflection.
- (b) Based on the graph of f , f is increasing on the intervals $(-\infty, -2)$ and $(0, 12)$ and decreasing on the intervals $(-2, 0)$ and $(12, \infty)$. Since f is continuous on its domain, we can say that f is
- increasing on the intervals $(-\infty, -2]$ and $[0, 12]$ and
 - decreasing on the intervals $[-2, 0]$ and $[12, \infty)$.

Additionally, f is concave down on the intervals $(-\infty, 0)$ and $(0, \infty)$. The function is never concave up.

12. (a) Based on the graph of f , f has
- a local maximum value at the point $(-2, 4)$,
 - a local minimum value at the point $(3, -1)$, and
 - a point of inflection at the point $(-2, 4)$.
- (b) Based on the graph of f , f is increasing on the intervals $(-7, -2)$ and $(3, \infty)$ and decreasing on the interval $(-2, 3)$. Since f is continuous on its domain, we can say that f is

increasing on the intervals $[-7, -2]$ and $[3, \infty)$ and decreasing on the interval $[-2, 3]$.

Additionally, f is concave up on the interval $(-2, \infty)$ and concave down on the interval $(-7, -2)$.

13. Let $f(x) = x^3 - 6x^2 + 2$.

- (a) The polynomial function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = 3x^2 - 12x = 3x(x - 4),$$

so 0 and 4 are critical numbers.

- (b) The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. These inequalities are solved by using the critical numbers 0 and 4 to form three intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $3x$	Sign of $x - 4$	Sign of $f'(x)$	Conclusion
$(-\infty, 0)$	−	−	+	f is increasing
$(0, 4)$	+	−	−	f is decreasing
$(4, \infty)$	+	+	+	f is increasing

Therefore, by the First Derivative Test, f has a local maximum value at 0 and a local minimum value at 4. The local maximum value is $f(0) = 2$; the local minimum value is $f(4) = -30$.

14. Let $f(x) = x^3 + 6x^2 + 12x + 1$.

- (a) The polynomial function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = 3x^2 + 12x + 12 = 3(x^2 + 4x + 4) = 3(x + 2)^2,$$

so -2 is the only critical number.

- (b) The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. Because $f'(x) = 3(x + 2)^2$ is positive for $x \neq -2$, f is increasing on the intervals $(-\infty, -2)$ and $(-2, \infty)$. Therefore, by the First Derivative Test, f has neither a local maximum value nor a local minimum value at -2 .

15. Let $f(x) = 3x^4 - 4x^3$.

- (a) The polynomial function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = 12x^3 - 12x^2 = 12x^2(x - 1),$$

so 0 and 1 are critical numbers.

- (b) The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. These inequalities are solved by using the critical numbers 0 and 1 to form three intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $12x^2$	Sign of $x - 1$	Sign of $f'(x)$	Conclusion
$(-\infty, 0)$	+	−	−	f is decreasing
$(0, 1)$	+	−	−	f is decreasing
$(1, \infty)$	+	+	+	f is increasing

Therefore, by the First Derivative Test, f has neither a local maximum value nor a local minimum value at 0 and a local minimum value at 1. The local minimum value is $f(1) = -1$.

16. Let $h(x) = x^4 + 2x^3 - 3$.

- (a) The polynomial function h is differentiable everywhere, so the critical numbers of h occur where $h'(x) = 0$. Now,

$$h'(x) = 4x^3 + 6x^2 = 2x^2(2x + 3),$$

so $-\frac{3}{2}$ and 0 are critical numbers.

- (b) The Increasing/Decreasing Function Test states that h is increasing on intervals where $h'(x) > 0$ and that h is decreasing on intervals where $h'(x) < 0$. These inequalities are solved by using the critical numbers $-\frac{3}{2}$ and 0 to form three intervals. The sign of $h'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $2x^2$	Sign of $2x + 3$	Sign of $h'(x)$	Conclusion
$(-\infty, -\frac{3}{2})$	+	-	-	h is decreasing
$(-\frac{3}{2}, 0)$	+	+	+	h is increasing
$(0, \infty)$	+	+	+	h is increasing

Therefore, by the First Derivative Test, h has a local minimum value at $-\frac{3}{2}$ and neither a local maximum value nor a local minimum value at 0. The local minimum value is $h\left(-\frac{3}{2}\right) = -\frac{75}{16}$.

17. Let $f(x) = (5 - 2x)e^x$.

- (a) The function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = (5 - 2x)e^x - 2e^x = (3 - 2x)e^x,$$

so $\frac{3}{2}$ is the only critical number.

- (b) The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. These inequalities are solved by using the critical number $\frac{3}{2}$ to form two intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $3 - 2x$	Sign of e^x	Sign of $f'(x)$	Conclusion
$(-\infty, \frac{3}{2})$	+	+	+	f is increasing
$(\frac{3}{2}, \infty)$	-	+	-	f is decreasing

Therefore, by the First Derivative Test, f has a local maximum value at $\frac{3}{2}$. The

$$\text{local maximum value is } f\left(\frac{3}{2}\right) = 2e^{3/2}.$$

18. Let $f(x) = (x - 8)e^x$.

- (a) The function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = (x - 8)e^x + e^x = (x - 7)e^x,$$

so 7 is the only critical number.

- (b) The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. These inequalities are solved by using the critical number 7 to form two intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $x - 7$	Sign of e^x	Sign of $f'(x)$	Conclusion
$(-\infty, 7)$	-	+	-	f is decreasing
$(7, \infty)$	+	+	+	f is increasing

Therefore, by the First Derivative Test, f has a local minimum value at 7. The local minimum value is $f(7) = -e^7$.

19. Let $g(u) = u^{-1}e^u$.

(a) The critical numbers of g occur where $g'(u) = 0$ or where $g'(u)$ does not exist. Now,

$$g'(u) = u^{-1}e^u - u^{-2}e^u = \frac{(u-1)e^u}{u^2},$$

so $g'(u) = 0$ when $u = 1$ and $g'(u)$ does not exist when $u = 0$. As 0 is not in the domain of g , 0 is not a critical number. Therefore, $\boxed{1}$ is the only critical number of g .

(b) The Increasing/Decreasing Function Test states that g is increasing on intervals where $g'(u) > 0$ and that g is decreasing on intervals where $g'(u) < 0$. These inequalities are solved by using 0 and the critical number 1 to form three intervals. The sign of $g'(u)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $u-1$	Sign of e^u	Sign of u^2	Sign of $g'(u)$	Conclusion
$(-\infty, 0)$	—	+	+	—	g is decreasing
$(0, 1)$	—	+	+	—	g is decreasing
$(1, \infty)$	+	+	+	+	g is increasing

Therefore, by the First Derivative Test, g has a local minimum value at 1. The local minimum value is $g(1) = e^1 = e$.

20. Let $f(x) = x^{-2}e^x$.

(a) The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now,

$$f'(x) = x^{-2}e^x - 2x^{-3}e^x = \frac{(x-2)e^x}{x^3},$$

so $f'(x) = 0$ when $x = 2$ and $f'(x)$ does not exist when $x = 0$. As 0 is not in the domain of f , 0 is not a critical number. Therefore, $\boxed{2}$ is the only critical number of f .

(b) The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. These inequalities are solved by using 0 and the critical number 2 to form three intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $x-2$	Sign of e^x	Sign of x^3	Sign of $f'(x)$	Conclusion
$(-\infty, 0)$	—	+	—	+	f is increasing
$(0, 2)$	—	+	+	—	f is decreasing
$(2, \infty)$	+	+	+	+	f is increasing

Therefore, by the First Derivative Test, f has a local minimum value at 2. The local minimum value is $f(2) = \frac{1}{4}e^2$. Note that f does not have a local maximum value at 0 because f is not defined at 0.

21. Let $f(x) = x^{2/3} + x^{1/3}$.

(a) The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now,

$$f'(x) = \frac{2}{3}x^{-1/3} + \frac{1}{3}x^{-2/3} = \frac{2x^{1/3} + 1}{3x^{2/3}},$$

so $f'(x) = 0$ when $x = -\frac{1}{8}$ and $f'(x)$ does not exist when $x = 0$. Therefore, $\boxed{-\frac{1}{8}}$ and $\boxed{0}$ are the critical numbers of f .

- (b) The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. These inequalities are solved by using the critical numbers $-\frac{1}{8}$ and 0 to form three intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $2x^{1/3} + 1$	Sign of $3x^{2/3}$	Sign of $f'(x)$	Conclusion
$(-\infty, -\frac{1}{8})$	—	+	—	f is decreasing
$(-\frac{1}{8}, 0)$	+	+	+	f is increasing
$(0, \infty)$	+	+	+	f is increasing

Therefore, by the First Derivative Test, f has a local minimum value at $-\frac{1}{8}$ but has neither a local maximum value nor a local minimum value at 0. The local minimum value is $f\left(-\frac{1}{8}\right) = -\frac{1}{4}$.

22. Let $f(x) = \frac{1}{2}x^{2/3} - x^{1/3}$.

- (a) The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now,

$$f'(x) = \frac{1}{3}x^{-1/3} - \frac{1}{3}x^{-2/3} = \frac{x^{1/3} - 1}{3x^{2/3}},$$

so $f'(x) = 0$ when $x = 1$ and $f'(x)$ does not exist when $x = 0$. Therefore, $\boxed{0 \text{ and } 1}$ are the critical numbers of f .

- (b) The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. These inequalities are solved by using the critical numbers 0 and 1 to form three intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $x^{1/3} - 1$	Sign of $3x^{2/3}$	Sign of $f'(x)$	Conclusion
$(-\infty, 0)$	—	+	—	f is decreasing
$(0, 1)$	—	+	—	f is decreasing
$(1, \infty)$	+	+	+	f is increasing

Therefore, by the First Derivative Test, f has neither a local maximum value nor a local minimum value at 0, but has a local minimum value at 1. The local minimum value is $f(1) = -\frac{1}{2}$.

23. Let $g(x) = x^{2/3}(x^2 - 4)$.

- (a) The critical numbers of g occur where $g'(x) = 0$ or where $g'(x)$ does not exist. Now,

$$g'(x) = x^{2/3}(2x) + \frac{2}{3}x^{-1/3}(x^2 - 4) = \frac{6x^2 + 2(x^2 - 4)}{3x^{1/3}} = \frac{8(x-1)(x+1)}{3x^{1/3}},$$

so $g'(x) = 0$ when $x = \pm 1$ and $g'(x)$ does not exist when $x = 0$. Therefore, $\boxed{-1, 0, \text{ and } 1}$ are the critical numbers of g .

- (b) The Increasing/Decreasing Function Test states that g is increasing on intervals where $g'(x) > 0$ and that g is decreasing on intervals where $g'(x) < 0$. These inequalities are solved by using the critical numbers -1 , 0, and 1 to form four intervals. The sign of $g'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $8(x-1)$	Sign of $x+1$	Sign of $3x^{1/3}$	Sign of $g'(x)$	Conclusion
$(-\infty, -1)$	—	—	—	—	g is decreasing
$(-1, 0)$	—	+	—	+	g is increasing
$(0, 1)$	—	+	+	—	g is decreasing
$(1, \infty)$	+	+	+	+	g is increasing

Therefore, by the First Derivative Test, g has a local minimum value at -1 , a local maximum value at 0 , and a local minimum value at 1 . The local minimum values are $g(-1) = -3$ and $g(1) = -3$, and the local maximum value is $g(0) = 0$.

24. Let $f(x) = x^{1/3}(x^2 - 9)$.

(a) The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now,

$$f'(x) = x^{1/3}(2x) + \frac{1}{3}x^{-2/3}(x^2 - 9) = \frac{6x^2 + (x^2 - 9)}{3x^{2/3}} = \frac{7x^2 - 9}{3x^{2/3}},$$

so $f'(x) = 0$ when $x = \pm \frac{3\sqrt{7}}{7}$ and $f'(x)$ does not exist when $x = 0$. Therefore, $-\frac{3\sqrt{7}}{7}$, 0 , and $\frac{3\sqrt{7}}{7}$ are the critical numbers of f .

(b) The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. These inequalities are solved by using the critical numbers $-\frac{3\sqrt{7}}{7}$, 0 , $\frac{3\sqrt{7}}{7}$ to form four intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $7x^2 - 9$	Sign of $3x^{2/3}$	Sign of $f'(x)$	Conclusion
$(-\infty, -\frac{3\sqrt{7}}{7})$	+	+	+	f is increasing
$(-\frac{3\sqrt{7}}{7}, 0)$	—	+	—	f is decreasing
$(0, \frac{3\sqrt{7}}{7})$	—	+	—	f is decreasing
$(\frac{3\sqrt{7}}{7}, \infty)$	+	+	+	f is increasing

Therefore, by the First Derivative Test, f has a local maximum value at $-\frac{3\sqrt{7}}{7}$, neither a local maximum value nor a local minimum value at 0 , and a local minimum value at $\frac{3\sqrt{7}}{7}$. The local maximum value is

$$f\left(-\frac{3\sqrt{7}}{7}\right) = \left(-\frac{3\sqrt{7}}{7}\right)^{1/3} \left(\frac{9}{7} - 9\right) \approx 8.044,$$

and the local minimum value is

$$f\left(\frac{3\sqrt{7}}{7}\right) = \left(\frac{3\sqrt{7}}{7}\right)^{1/3} \left(\frac{9}{7} - 9\right) \approx -8.044.$$

25. Let $f(x) = \frac{\ln x}{x^3}$.

- (a) The function f is differentiable on its domain, the set $\{x|x > 0\}$, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = \frac{x^3 \cdot \frac{1}{x} - 3x^2 \ln x}{x^6} = \frac{1 - 3 \ln x}{x^4},$$

so $f'(x) = 0$ when $x = \sqrt[3]{e}$. Therefore, $\sqrt[3]{e}$ is the only critical number of f .

- (b) The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. These inequalities are solved by using the critical number $\sqrt[3]{e}$ to form two intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $1 - 3 \ln x$	Sign of x^4	Sign of $f'(x)$	Conclusion
$(0, \sqrt[3]{e})$	+	+	+	f is increasing
$(\sqrt[3]{e}, \infty)$	-	+	-	f is decreasing

Therefore, by the First Derivative Test, f has a local maximum value at $\sqrt[3]{e}$. The

local maximum value is $f(\sqrt[3]{e}) = \frac{1}{3e}$.

26. Let $h(x) = \frac{\ln x}{\sqrt{x^3}}$.

- (a) The function h is differentiable on its domain, the set $\{x|x > 0\}$, so the critical numbers of h occur where $h'(x) = 0$. Now,

$$h'(x) = \frac{x^{3/2} \cdot \frac{1}{x} - \frac{3}{2}x^{1/2} \ln x}{x^3} = \frac{2 - 3 \ln x}{2x^{5/2}},$$

so $h'(x) = 0$ when $x = \sqrt[3]{e^2}$. Therefore, $\sqrt[3]{e^2}$ is the only critical number of h .

- (b) The Increasing/Decreasing Function Test states that h is increasing on intervals where $h'(x) > 0$ and that h is decreasing on intervals where $h'(x) < 0$. These inequalities are solved by using the critical number $\sqrt[3]{e^2}$ to form two intervals. The sign of $h'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $2 - 3 \ln x$	Sign of $2x^{5/2}$	Sign of $h'(x)$	Conclusion
$(0, \sqrt[3]{e^2})$	+	+	+	h is increasing
$(\sqrt[3]{e^2}, \infty)$	-	+	-	h is decreasing

Therefore, by the First Derivative Test, h has a local maximum value at $\sqrt[3]{e^2}$. The

local maximum value is $h(\sqrt[3]{e^2}) = \frac{2}{3e}$.

27. Let

$$g(x) = |x^2 - 1| = \begin{cases} x^2 - 1, & x \leq -1 \\ -(x^2 - 1), & -1 < x < 1 \\ x^2 - 1, & x \geq 1. \end{cases}$$

- (a) On the interval $(-\infty, -1)$, $g'(x) = 2x$ exists and is never equal to 0; g has no critical numbers on this interval. On the interval $(-1, 1)$, $g'(x) = -2x$ exists and is equal to 0 when $x = 0$. Therefore, 0 is a critical number. On the interval $(1, \infty)$, $g'(x) = 2x$ exists and is never equal to 0; g has

no critical numbers on this interval. At $x = \pm 1$, the rule for g changes, so it is necessary to investigate the existence of $g'(-1)$ and $g'(1)$. Now,

$$\lim_{x \rightarrow -1^-} \frac{g(x) - g(-1)}{x - (-1)} = \lim_{x \rightarrow -1^-} \frac{(x^2 - 1) - 0}{x + 1} = \lim_{x \rightarrow -1^-} \frac{(x - 1)(x + 1)}{x + 1} = \lim_{x \rightarrow -1^-} (x - 1) = -2,$$

and

$$\lim_{x \rightarrow -1^+} \frac{g(x) - g(-1)}{x - (-1)} = \lim_{x \rightarrow -1^+} \frac{-(x^2 - 1) - 0}{x + 1} = \lim_{x \rightarrow -1^+} \frac{-(x - 1)(x + 1)}{x + 1} = \lim_{x \rightarrow -1^+} -(x - 1) = 2.$$

Because these two one-sided limits are not equal, $g'(x)$ does not exist at $x = -1$. Additionally,

$$\lim_{x \rightarrow 1^-} \frac{g(x) - g(1)}{x - 1} = \lim_{x \rightarrow 1^-} \frac{-(x^2 - 1) - 0}{x - 1} = \lim_{x \rightarrow 1^-} \frac{-(x - 1)(x + 1)}{x - 1} = \lim_{x \rightarrow 1^-} -(x + 1) = -2,$$

and

$$\lim_{x \rightarrow 1^+} \frac{g(x) - g(1)}{x - 1} = \lim_{x \rightarrow 1^+} \frac{(x^2 - 1) - 0}{x - 1} = \lim_{x \rightarrow 1^+} \frac{(x - 1)(x + 1)}{x - 1} = \lim_{x \rightarrow 1^+} (x + 1) = 2.$$

Because these two one-sided limits are not equal, $g'(x)$ does not exist at $x = 1$. Therefore, $\boxed{\pm 1}$ are also critical numbers of g .

- (b) The Increasing/Decreasing Function Test states that g is increasing on intervals where $g'(x) > 0$ and that g is decreasing on intervals where $g'(x) < 0$. On the interval $(-\infty, -1)$, $g'(x) = 2x < 0$; on the interval $(-1, 0)$, $g'(x) = -2x > 0$; on the interval $(0, 1)$, $g'(x) = -2x < 0$; finally, on the interval $(1, \infty)$, $g'(x) = 2x > 0$. Therefore, g is decreasing on the intervals $(-\infty, -1)$ and $(0, 1)$ and increasing on the intervals $(-1, 0)$ and $(1, \infty)$. By the First Derivative Test, it follows that g has a local minimum value at -1 , a local maximum value at 0 , and a local minimum value at 1 . The local minimum values are $g(-1) = 0$ and $g(1) = 0$, and the local maximum value is $g(0) = 1$.

28. Let

$$f(x) = |x^2 - 4| = \begin{cases} x^2 - 4, & x \leq -2 \\ -(x^2 - 4), & -2 < x < 2 \\ x^2 - 4, & x \geq 2. \end{cases}$$

- (a) On the interval $(-\infty, -2)$, $f'(x) = 2x$ exists and is never equal to 0; f has no critical numbers on this interval. On the interval $(-2, 2)$, $f'(x) = -2x$ exists and is equal to 0 when $x = 0$. Therefore, $\boxed{0}$ is a critical number. On the interval $(2, \infty)$, $f'(x) = 2x$ exists and is never equal to 0; f has no critical numbers on this interval. At $x = \pm 2$, the rule for f changes, so it is necessary to investigate the existence of $f'(-2)$ and $f'(2)$. Now,

$$\lim_{x \rightarrow -2^-} \frac{f(x) - f(-2)}{x - (-2)} = \lim_{x \rightarrow -2^-} \frac{(x^2 - 4) - 0}{x + 2} = \lim_{x \rightarrow -2^-} \frac{(x - 2)(x + 2)}{x + 2} = \lim_{x \rightarrow -2^-} (x - 2) = -4,$$

and

$$\lim_{x \rightarrow -2^+} \frac{f(x) - f(-2)}{x - (-2)} = \lim_{x \rightarrow -2^+} \frac{-(x^2 - 4) - 0}{x + 2} = \lim_{x \rightarrow -2^+} \frac{-(x - 2)(x + 2)}{x + 2} = \lim_{x \rightarrow -2^+} -(x - 2) = 4.$$

Because these two one-sided limits are not equal, $f'(x)$ does not exist at $x = -2$. Additionally,

$$\lim_{x \rightarrow 2^-} \frac{f(x) - f(2)}{x - 2} = \lim_{x \rightarrow 2^-} \frac{-(x^2 - 4) - 0}{x - 2} = \lim_{x \rightarrow 2^-} \frac{-(x - 2)(x + 2)}{x - 2} = \lim_{x \rightarrow 2^-} -(x + 2) = -4,$$

and

$$\lim_{x \rightarrow 2^+} \frac{f(x) - f(2)}{x - 2} = \lim_{x \rightarrow 2^+} \frac{(x^2 - 4) - 0}{x - 2} = \lim_{x \rightarrow 2^+} \frac{(x - 2)(x + 2)}{x - 2} = \lim_{x \rightarrow 2^+} (x + 2) = 4.$$

Because these two one-sided limits are not equal, $f'(x)$ does not exist at $x = 2$. Therefore, $\boxed{\pm 2}$ are also critical numbers of f .

- (b) The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. On the interval $(-\infty, -2)$, $f'(x) = 2x < 0$; on the interval $(-2, 0)$, $f'(x) = -2x > 0$; on the interval $(0, 2)$, $f'(x) = -2x < 0$; finally, on the interval $(2, \infty)$, $f'(x) = 2x > 0$. Therefore, f is decreasing on the intervals $(-\infty, -2)$ and $(0, 2)$ and increasing on the intervals $(-2, 0)$ and $(2, \infty)$. By the First Derivative Test, it follows that f has a local minimum value at -2 , a local maximum value at 0 , and a local minimum value at 2 . The local minimum values are $f(-2) = 0$ and $f(2) = 0$, and the local maximum value is $f(0) = 4$.

29. Let $f(\theta) = \sin \theta - 2 \cos \theta$.

- (a) The function f is the difference of the trigonometric function $\sin x$ and a constant multiple of the trigonometric function $\cos x$, so it is differentiable everywhere. The critical numbers of f therefore occur where $f'(\theta) = 0$. Now,

$$f'(\theta) = \cos \theta + 2 \sin \theta,$$

so $f'(\theta) = 0$ when $\cos \theta = -2 \sin \theta$ or $\tan \theta = -\frac{1}{2}$. It follows that the critical numbers of f are

$-\tan^{-1} \frac{1}{2} + k\pi$, where k is any integer. Remember that the tangent function is periodic with period π .

- (b) The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(\theta) > 0$ and that f is decreasing on intervals where $f'(\theta) < 0$. The critical numbers of f divide the number line into intervals of the form

$$\left(-\tan^{-1} \frac{1}{2} + 2k\pi, -\tan^{-1} \frac{1}{2} + (2k+1)\pi \right)$$

and

$$\left(-\tan^{-1} \frac{1}{2} + (2k+1)\pi, -\tan^{-1} \frac{1}{2} + (2k+2)\pi \right)$$

for each integer k . Select a test number in each interval and evaluate f' at that number. If $f'(\theta) < 0$ at the test number, then $f'(\theta) < 0$ throughout the interval; if $f'(\theta) > 0$ at the test number, then $f'(\theta) > 0$ throughout the interval. The following table summarizes the results:

Interval	Test Number	Value of $f'(\theta)$ at Test Number	Sign of $f'(\theta)$	Conclusion
$\left(-\tan^{-1} \frac{1}{2} + 2k\pi, -\tan^{-1} \frac{1}{2} + (2k+1)\pi \right)$	$2k\pi$	1	+	f is increasing
$\left(-\tan^{-1} \frac{1}{2} + (2k+1)\pi, -\tan^{-1} \frac{1}{2} + (2k+2)\pi \right)$	$(2k+1)\pi$	-1	-	f is decreasing

Therefore, f is increasing on the intervals $\left(-\tan^{-1} \frac{1}{2} + 2k\pi, -\tan^{-1} \frac{1}{2} + (2k+1)\pi \right)$ and decreasing on the intervals $\left(-\tan^{-1} \frac{1}{2} + (2k+1)\pi, -\tan^{-1} \frac{1}{2} + (2k+2)\pi \right)$. By the First Derivative Test, it follows that f has a local maximum value at all points of the form $-\tan^{-1} \frac{1}{2} + (2k+1)\pi$ and a local minimum value at all points of the form $-\tan^{-1} \frac{1}{2} + 2k\pi$. The local maximum values are

$$\begin{aligned} f\left(-\tan^{-1} \frac{1}{2} + (2k+1)\pi\right) &= \sin\left(-\tan^{-1} \frac{1}{2} + (2k+1)\pi\right) - 2\cos\left(-\tan^{-1} \frac{1}{2} + (2k+1)\pi\right) \\ &= \sin\left(\tan^{-1} \frac{1}{2}\right) + 2\cos\left(\tan^{-1} \frac{1}{2}\right) = \frac{1}{\sqrt{5}} + 2\frac{2}{\sqrt{5}} = \frac{5}{\sqrt{5}} = \boxed{\sqrt{5}}, \end{aligned}$$

and the local minimum values are

$$\begin{aligned} f\left(-\tan^{-1}\frac{1}{2} + 2k\pi\right) &= \sin\left(-\tan^{-1}\frac{1}{2} + 2k\pi\right) - 2\cos\left(-\tan^{-1}\frac{1}{2} + 2k\pi\right) \\ &= -\sin\left(\tan^{-1}\frac{1}{2}\right) - 2\cos\left(\tan^{-1}\frac{1}{2}\right) = -\frac{1}{\sqrt{5}} - 2\frac{2}{\sqrt{5}} = -\frac{5}{\sqrt{5}} = \boxed{-\sqrt{5}}. \end{aligned}$$

30. Let $f(x) = x + 2\sin x$.

- (a) The function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = 1 + 2\cos x,$$

so $f'(x) = 0$ when $\cos x = -\frac{1}{2}$. Therefore, the critical numbers of f are $\boxed{\frac{2\pi}{3} + 2k\pi}$ and $\boxed{\frac{4\pi}{3} + 2k\pi}$, where k is any integer.

- (b) The Increasing/Decreasing Function Test states that f is increasing on intervals where $f'(x) > 0$ and that f is decreasing on intervals where $f'(x) < 0$. The critical numbers of f divide the number line into intervals of the form

$$\left(\frac{2\pi}{3} + 2k\pi, \frac{4\pi}{3} + 2k\pi\right) \quad \text{and} \quad \left(\frac{4\pi}{3} + 2k\pi, \frac{2\pi}{3} + 2(k+1)\pi\right),$$

for each integer k . Select a test number in each interval and evaluate f' at that number. If $f'(x) < 0$ at the test number, then $f'(x) < 0$ throughout the interval; if $f'(x) > 0$ at the test number, then $f'(x) > 0$ throughout the interval. The following table summarizes the results:

Interval	Test Number	Value of $f'(x)$ at Test Number	Sign of $f'(x)$	Conclusion
$\left(\frac{2\pi}{3} + 2k\pi, \frac{4\pi}{3} + 2k\pi\right)$	$\pi + 2k\pi$	-1	$-$	f is decreasing
$\left(\frac{4\pi}{3} + 2k\pi, \frac{2\pi}{3} + 2(k+1)\pi\right)$	$2(k+1)\pi$	3	$+$	f is increasing

Therefore, f is decreasing on the intervals $\left(\frac{2\pi}{3} + 2k\pi, \frac{4\pi}{3} + 2k\pi\right)$ and increasing on the intervals $\left(\frac{4\pi}{3} + 2k\pi, \frac{2\pi}{3} + 2(k+1)\pi\right)$. By the First Derivative Test, it follows that f has a local minimum value at all points of the form $\frac{4\pi}{3} + 2k\pi$ and a local maximum value at all points of the form $\frac{2\pi}{3} + 2k\pi$. The local minimum values are

$$\boxed{f\left(\frac{4\pi}{3} + 2k\pi\right) = \frac{4\pi}{3} + 2k\pi + 2\sin\left(\frac{4\pi}{3} + 2k\pi\right) = \frac{4\pi}{3} + 2k\pi - \sqrt{3}},$$

and the local maximum values are

$$\boxed{f\left(\frac{2\pi}{3} + 2k\pi\right) = \frac{2\pi}{3} + 2k\pi + 2\sin\left(\frac{2\pi}{3} + 2k\pi\right) = \frac{2\pi}{3} + 2k\pi + \sqrt{3}}.$$

31. Let $s = t^2 - 2t + 3$.

- (a) The object moves to the right when $v(t) = s'(t) > 0$ and moves to the left when $v(t) = s'(t) < 0$. Now,

$$v(t) = s'(t) = 2t - 2 = 2(t - 1),$$

so 1 is the only critical number of s . When $t < 1$, $v(t) < 0$ and when $t > 1$, $v(t) > 0$. Therefore, the object moves to the right on the interval $(1, \infty)$ and moves to the left on the interval $(0, 1)$.

- (b) The object reverses direction at $t = 1$.
- (c) The velocity of the object is increasing when $a(t) = v'(t) > 0$ and is decreasing when $a(t) = v'(t) < 0$. Now

$$a(t) = v'(t) = 2 > 0$$

for all $t \geq 0$. Therefore, the velocity is increasing on the interval $(0, \infty)$.

- (d) The figure below illustrates the motion of the object.

- (e) The figure below illustrates the velocity of the object.

32. Let $s = 2t^2 + 8t - 7$.

- (a) The object moves to the right when $v(t) = s'(t) > 0$ and moves to the left when $v(t) = s'(t) < 0$. Now,

$$v(t) = s'(t) = 4t + 8 = 4(t + 2).$$

As the domain of s is the set $\{t | t \geq 0\}$ and -2 is not in this domain, -2 is not a critical number. Because $v(t) > 0$ for all $t \geq 0$, the object moves to the right on the interval $(0, \infty)$.

- (b) The object does not reverse direction.
- (c) The velocity of the object is increasing when $a(t) = v'(t) > 0$ and is decreasing when $a(t) = v'(t) < 0$. Now

$$a(t) = v'(t) = 4 > 0$$

for all $t \geq 0$. Therefore, the velocity is increasing on the interval $(0, \infty)$.

- (d) The figure below illustrates the motion of the object.

- (e) The figure below illustrates the velocity of the object.

33. Let $s = 2t^3 + 6t^2 - 18t + 1$.

- (a) The object moves to the right when $v(t) = s'(t) > 0$ and moves to the left when $v(t) = s'(t) < 0$. Now,

$$v(t) = s'(t) = 6t^2 + 12t - 18 = 6(t^2 + 2t - 3) = 6(t + 3)(t - 1).$$

As the domain of s is the set $\{t | t \geq 0\}$ and -3 is not in this domain, -3 is not a critical number. When $t < 1$, $v(t) < 0$ and when $t > 1$, $v(t) > 0$. Therefore, the object moves to the right on the interval $(1, \infty)$ and moves to the left on the interval $(0, 1)$.

(b) The object reverses direction at $t = 1$.

(c) The velocity of the object is increasing when $a(t) = v'(t) > 0$ and is decreasing when $a(t) = v'(t) < 0$. Now

$$a(t) = v'(t) = 12t + 12 = 12(t + 1) > 0$$

for all $t \geq 0$. Therefore, the velocity is increasing on the interval $(0, \infty)$.

(d) The figure below illustrates the motion of the object.

(e) The figure below illustrates the velocity of the object.

34. Let $s = 3t^4 - 16t^3 + 24t^2$.

(a) The object moves to the right when $v(t) = s'(t) > 0$ and moves to the left when $v(t) = s'(t) < 0$. Now,

$$v(t) = s'(t) = 12t^3 - 48t^2 + 48t = 12t(t^2 - 4t + 4) = 12t(t - 2)^2,$$

so $v(t) > 0$ on the intervals $(0, 2)$ and $(2, \infty)$. Therefore, the object is moving to the right on the intervals $(0, 2)$ and $(2, \infty)$.

(b) The object does not reverse direction.

(c) The velocity of the object is increasing when $a(t) = v'(t) > 0$ and is decreasing when $a(t) = v'(t) < 0$. Now

$$a(t) = v'(t) = 36t^2 - 96t + 48 = 12(3t^2 - 8t + 4) = 12(3t - 2)(t - 2).$$

When $t < \frac{2}{3}$ and when $t > 2$, $a(t) > 0$; when $\frac{2}{3} < t < 2$, $a(t) < 0$. Therefore, the velocity of the ob-

ject is increasing on the intervals $\left(0, \frac{2}{3}\right)$ and $(2, \infty)$, and the velocity is decreasing on the interval $\left(\frac{2}{3}, 2\right)$.

(d) The figure below illustrates the motion of the object.

(e) The figure below illustrates the velocity of the object.

35. Let $s = 2t - \frac{6}{t}$.

- (a) The object moves to the right when $v(t) = s'(t) > 0$ and moves to the left when $v(t) = s'(t) < 0$. Now,

$$v(t) = s'(t) = 2 + \frac{6}{t^2} > 0$$

for all $t > 0$. Therefore, the object is moving to the right on the interval $(0, \infty)$.

- (b) The object does not reverse direction.

- (c) The velocity of the object is increasing when $a(t) = v'(t) > 0$ and is decreasing when $a(t) = v'(t) < 0$. Now

$$a(t) = v'(t) = -\frac{12}{t^3} < 0$$

for all $t > 0$. Therefore, the velocity of the object is decreasing on the interval $(0, \infty)$.

- (d) The figure below illustrates the motion of the object.

- (e) The figure below illustrates the velocity of the object.

36. Let $s = 3\sqrt{t} - \frac{1}{\sqrt{t}}$.

- (a) The object moves to the right when $v(t) = s'(t) > 0$ and moves to the left when $v(t) = s'(t) < 0$. Now,

$$v(t) = s'(t) = \frac{3}{2\sqrt{t}} + \frac{1}{2\sqrt{t^3}} = \frac{3t+1}{2\sqrt{t^3}} > 0$$

for all $t > 0$. Therefore, the object is moving to the right on the interval $(0, \infty)$.

- (b) The object does not reverse direction.

- (c) The velocity of the object is increasing when $a(t) = v'(t) > 0$ and is decreasing when $a(t) = v'(t) < 0$. Now

$$a(t) = v'(t) = -\frac{3}{4\sqrt{t^3}} - \frac{3}{4\sqrt{t^5}} = -\frac{3}{4} \frac{t+1}{\sqrt{t^5}} < 0$$

for all $t > 0$. Therefore, the velocity of the object is decreasing on the interval $(0, \infty)$.

- (d) The figure below illustrates the motion of the object.

(e) The figure below illustrates the velocity of the object.

37. Let $s = 2 \sin(3t)$ for $0 \leq t \leq \frac{2\pi}{3}$.

(a) The object moves to the right when $v(t) = s'(t) > 0$ and moves to the left when $v(t) = s'(t) < 0$. Now,

$$v(t) = s'(t) = 6 \cos(3t).$$

When $0 < t < \frac{\pi}{6}$, $v(t) > 0$; when $\frac{\pi}{6} < t < \frac{\pi}{2}$, $v(t) < 0$; and when $\frac{\pi}{2} < t < \frac{2\pi}{3}$, $v(t) > 0$.

Therefore, the object is moving to the right on the intervals $\left(0, \frac{\pi}{6}\right)$ and $\left(\frac{\pi}{2}, \frac{2\pi}{3}\right)$ and is moving to the left on the interval $\left(\frac{\pi}{6}, \frac{\pi}{2}\right)$.

(b) The object reverses direction at $t = \frac{\pi}{6}$ and $t = \frac{\pi}{2}$.

(c) The velocity of the object is increasing when $a(t) = v'(t) > 0$ and is decreasing when $a(t) = v'(t) < 0$. Now,

$$a(t) = v'(t) = -18 \sin(3t).$$

When $0 < t < \frac{\pi}{3}$, $a(t) < 0$, and when $\frac{\pi}{3} < t < \frac{2\pi}{3}$, $a(t) > 0$. Therefore, the velocity of the object

is decreasing on the interval $\left(0, \frac{\pi}{3}\right)$ and is increasing on the interval $\left(\frac{\pi}{3}, \frac{2\pi}{3}\right)$.

(d) The figure below illustrates the motion of the object.

(e) The figure below illustrates the velocity of the object.

38. Let $s = 3 \cos(\pi t)$ for $0 \leq t \leq 2$.

- (a) The object moves to the right when $v(t) = s'(t) > 0$ and moves to the left when $v(t) = s'(t) < 0$. Now,

$$v(t) = s'(t) = -3\pi \sin(\pi t).$$

When $0 < t < 1$, $v(t) < 0$, and when $1 < t < 2$, $v(t) > 0$. Therefore, the object is moving to the left on the interval $(0, 1)$ and is moving to the right on the interval $(1, 2)$.

- (b) The object reverses direction at $t = 1$.
 (c) The velocity of the object is increasing when $a(t) = v'(t) > 0$ and is decreasing when $a(t) = v'(t) < 0$. Now,

$$a(t) = v'(t) = -3\pi^2 \cos(\pi t).$$

When $0 < t < \frac{1}{2}$, $a(t) < 0$; when $\frac{1}{2} < t < \frac{3}{2}$, $a(t) > 0$; and when $\frac{3}{2} < t < 2$, $a(t) < 0$.

Therefore, the velocity of the object is decreasing on the intervals $(0, \frac{1}{2})$ and $(\frac{3}{2}, 2)$ and is

increasing on the interval $(\frac{1}{2}, \frac{3}{2})$.

- (d) The figure below illustrates the motion of the object.

- (e) The figure below illustrates the velocity of the object.

39. Let $f(x) = x^2 - 2x + 5$.

- (a) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f'(x) = 2x - 2 \quad \text{and} \quad f''(x) = 2 > 0$$

for all x . Therefore, f is concave up on the interval $(-\infty, \infty)$.

- (b) Because the concavity of f never changes, f has no points of inflection.

40. Let $f(x) = x^2 + 4x - 2$.

- (a) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f'(x) = 2x + 4 \quad \text{and} \quad f''(x) = 2 > 0$$

for all x . Therefore, f is concave up on the interval $(-\infty, \infty)$.

- (b) Because the concavity of f never changes, f has no points of inflection.

41. Let $f(x) = x^3 - 9x^2 + 2$.

(a) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f'(x) = 3x^2 - 18x \quad \text{and} \quad f''(x) = 6x - 18 = 6(x - 3),$$

so $f''(x) > 0$ when $x > 3$ and $f''(x) < 0$ when $x < 3$. Therefore, f is
concave up on the interval $(3, \infty)$ and concave down on the interval $(-\infty, 3)$.

(b) Because the concavity of f changes at 3, the point $(3, f(3)) = (3, -52)$ is a point of inflection of f .

42. Let $f(x) = x^3 - 6x^2 + 9x + 1$.

(a) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f'(x) = 3x^2 - 12x + 9 \quad \text{and} \quad f''(x) = 6x - 12 = 6(x - 2),$$

so $f''(x) > 0$ when $x > 2$ and $f''(x) < 0$ when $x < 2$. Therefore, f is
concave up on the interval $(2, \infty)$ and concave down on the interval $(-\infty, 2)$.

(b) Because the concavity of f changes at 2, the point $(2, f(2)) = (2, 3)$ is a point of inflection of f .

43. Let $f(x) = x^4 - 4x^3 + 10$.

(a) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f'(x) = 4x^3 - 12x^2 \quad \text{and} \quad f''(x) = 12x^2 - 24x = 12x(x - 2),$$

so $f''(x) = 0$ when $x = 0$ and when $x = 2$. To determine where $f''(x) > 0$ and $f''(x) < 0$, use the numbers 0 and 2 to divide the number line into three intervals. The sign of $f''(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $12x$	Sign of $x - 2$	Sign of $f''(x)$	Conclusion
$(-\infty, 0)$	—	—	+	f is concave up
$(0, 2)$	+	—	—	f is concave down
$(2, \infty)$	+	+	+	f is concave up

Therefore, f is concave up on the intervals $(-\infty, 0)$ and $(2, \infty)$ and is
concave down on the interval $(0, 2)$.

(b) Because the concavity of f changes at 0 and 2, the points $(0, f(0)) = (0, 10)$ and $(2, f(2)) = (2, -6)$ are points of inflection of f .

44. Let $f(x) = 3x^4 - 8x^3 + 6x + 1$.

(a) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f'(x) = 12x^3 - 24x^2 + 6 \quad \text{and} \quad f''(x) = 36x^2 - 48x = 12x(3x - 4),$$

so $f''(x) = 0$ when $x = 0$ and when $x = \frac{4}{3}$. To determine where $f''(x) > 0$ and $f''(x) < 0$, use the numbers 0 and $\frac{4}{3}$ to divide the number line into three intervals. The sign of $f''(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $12x$	Sign of $3x - 4$	Sign of $f''(x)$	Conclusion
$(-\infty, 0)$	-	-	+	f is concave up
$(0, \frac{4}{3})$	+	-	-	f is concave down
$(\frac{4}{3}, \infty)$	+	+	+	f is concave up

Therefore, f is concave up on the intervals $(-\infty, 0)$ and $(\frac{4}{3}, \infty)$ and is concave down on the interval $(0, \frac{4}{3})$.

- (b) Because the concavity of f changes at 0 and $\frac{4}{3}$, the points $(0, f(0)) = (0, 1)$ and $(\frac{4}{3}, f(\frac{4}{3})) = (\frac{4}{3}, -\frac{13}{27})$ are points of inflection of f .

45. Let $f(x) = x^{2/3}e^x$.

- (a) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f'(x) = x^{2/3}e^x + \frac{2}{3}x^{-1/3}e^x = \frac{e^x(3x+2)}{3x^{1/3}},$$

and

$$\begin{aligned} f''(x) &= \frac{3x^{1/3}[e^x(3) + (3x+2)e^x] - e^x(3x+2)x^{-2/3}}{9x^{2/3}} \\ &= \frac{3x(3x+5)e^x - (3x+2)e^x}{9x^{4/3}} = \frac{e^x(9x^2 + 12x - 2)}{9x^{4/3}}, \end{aligned}$$

so $f''(x) = 0$ when

$$x = \frac{-12 \pm \sqrt{12^2 - 4(9)(-2)}}{18} = \frac{-12 \pm \sqrt{216}}{18} = \frac{-12 \pm 6\sqrt{6}}{18} = \frac{-2 \pm \sqrt{6}}{3}$$

and $f''(x)$ does not exist when $x = 0$. To determine where $f''(x) > 0$ and $f''(x) < 0$, use the numbers 0 and $\frac{-2 \pm \sqrt{6}}{3}$ to divide the number line into four intervals. The sign of $f''(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $9x^2 + 12x - 2$	Sign of $e^x/(9x^{4/3})$	Sign of $f''(x)$	Conclusion
$(-\infty, \frac{-2-\sqrt{6}}{3})$	+	+	+	f is concave up
$(\frac{-2-\sqrt{6}}{3}, 0)$	-	+	-	f is concave down
$(0, \frac{-2+\sqrt{6}}{3})$	-	+	-	f is concave down
$(\frac{-2+\sqrt{6}}{3}, \infty)$	+	+	+	f is concave up

Therefore, f is concave up on the intervals

$$\left(-\infty, \frac{-2-\sqrt{6}}{3}\right) \quad \text{and} \quad \left(\frac{-2+\sqrt{6}}{3}, \infty\right)$$

and is concave down on the intervals

$$\left(\frac{-2 - \sqrt{6}}{3}, 0 \right) \quad \text{and} \quad \left(0, \frac{-2 + \sqrt{6}}{3} \right).$$

- (b) Because the concavity of f changes at $\frac{-2 - \sqrt{6}}{3}$ and $\frac{-2 + \sqrt{6}}{3}$, the points

$$\left(\frac{-2 - \sqrt{6}}{3}, f\left(\frac{-2 - \sqrt{6}}{3}\right) \right) \approx (-1.483, 0.295)$$

and

$$\left(\frac{-2 + \sqrt{6}}{3}, f\left(\frac{-2 + \sqrt{6}}{3}\right) \right) \approx (0.150, 0.328)$$

are points of inflection of f . The concavity of f does not change at 0, so the point $(0, f(0)) = (0, 0)$ is not a point of inflection.

46. Let $f(x) = x^{2/3}e^{-x}$.

- (a) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f'(x) = -x^{2/3}e^{-x} + \frac{2}{3}x^{-1/3}e^{-x} = \frac{e^{-x}(2 - 3x)}{3x^{1/3}},$$

and

$$\begin{aligned} f''(x) &= \frac{3x^{1/3}[e^{-x}(-3) - (2 - 3x)e^{-x}] - e^{-x}(2 - 3x)x^{-2/3}}{9x^{2/3}} \\ &= \frac{3x(3x - 5)e^{-x} - (2 - 3x)e^{-x}}{9x^{4/3}} = \frac{e^{-x}(9x^2 - 12x - 2)}{9x^{4/3}}, \end{aligned}$$

so $f''(x) = 0$ when

$$x = \frac{12 \pm \sqrt{(-12)^2 - 4(9)(-2)}}{18} = \frac{12 \pm \sqrt{216}}{18} = \frac{12 \pm 6\sqrt{6}}{18} = \frac{2 \pm \sqrt{6}}{3}$$

and $f''(x)$ does not exist when $x = 0$. To determine where $f''(x) > 0$ and $f''(x) < 0$, use the numbers 0 and $\frac{2 \pm \sqrt{6}}{3}$ to divide the number line into four intervals. The sign of $f''(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $9x^2 - 12x - 2$	Sign of $e^{-x}/(9x^{4/3})$	Sign of $f''(x)$	Conclusion
$\left(-\infty, \frac{2 - \sqrt{6}}{3}\right)$	+	+	+	f is concave up
$\left(\frac{2 - \sqrt{6}}{3}, 0\right)$	-	+	-	f is concave down
$\left(0, \frac{2 + \sqrt{6}}{3}\right)$	-	+	-	f is concave down
$\left(\frac{2 + \sqrt{6}}{3}, \infty\right)$	+	+	+	f is concave up

Therefore, f is concave up on the intervals

$$\left(-\infty, \frac{2 - \sqrt{6}}{3} \right) \quad \text{and} \quad \left(\frac{2 + \sqrt{6}}{3}, \infty \right)$$

and is concave down on the intervals

$$\left(\frac{2 - \sqrt{6}}{3}, 0 \right) \quad \text{and} \quad \left(0, \frac{2 + \sqrt{6}}{3} \right).$$

- (b) Because the concavity of f changes at $\frac{2 - \sqrt{6}}{3}$ and $\frac{2 + \sqrt{6}}{3}$, the points

$$\left(\frac{2 - \sqrt{6}}{3}, f\left(\frac{2 - \sqrt{6}}{3}\right) \right) \approx (-0.150, 0.328)$$

and

$$\left(\frac{2 + \sqrt{6}}{3}, f\left(\frac{2 + \sqrt{6}}{3}\right) \right) \approx (1.483, 0.295)$$

are points of inflection of f . The concavity of f does not change at 0, so the point $(0, f(0)) = (0, 0)$ is not a point of inflection.

47. Let $f(x) = \frac{\ln x}{x^3}$.

- (a) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f'(x) = \frac{x^3 \cdot \frac{1}{x} - 3x^2 \ln x}{x^6} = \frac{1 - 3 \ln x}{x^4},$$

and

$$f''(x) = \frac{x^4 \cdot \left(-\frac{3}{x}\right) - 4x^3(1 - 3 \ln x)}{x^8} = \frac{-3x^3 - 4x^3 + 12x^3 \ln x}{x^8} = \frac{12 \ln x - 7}{x^5},$$

so $f''(x)$ exists on the domain of f , the set $\{x|x > 0\}$, and $f''(x) = 0$ when $x = e^{7/12}$. When $0 < x < e^{7/12}$, $f''(x) < 0$, and when $x > e^{7/12}$, $f''(x) > 0$. Therefore, f is concave down on the interval $(0, e^{7/12})$ and is concave up on the interval $(e^{7/12}, \infty)$.

- (b) Because the concavity of f changes at $e^{7/12}$, the point $(e^{7/12}, f(e^{7/12})) = \left(e^{7/12}, \frac{7}{12}e^{-7/4}\right)$ is a point of inflection of f .

48. Let $f(x) = \frac{\ln x}{\sqrt{x^3}}$.

- (a) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f'(x) = \frac{\sqrt{x^3} \cdot \frac{1}{x} - \frac{3}{2}\sqrt{x} \ln x}{x^3} = \frac{2 - 3 \ln x}{2x^{5/2}},$$

and

$$f''(x) = \frac{2x^{5/2} \cdot \left(-\frac{3}{x}\right) - 5x^{3/2}(2 - 3 \ln x)}{4x^5} = \frac{-6x^{3/2} - 10x^{3/2} + 15x^{3/2} \ln x}{4x^5} = \frac{15 \ln x - 16}{4x^{7/2}},$$

so $f''(x)$ exists on the domain of f , the set $\{x|x > 0\}$, and $f''(x) = 0$ when $x = e^{16/15}$. When $0 < x < e^{16/15}$, $f''(x) < 0$, and when $x > e^{16/15}$, $f''(x) > 0$. Therefore, f is concave down on the interval $(0, e^{16/15})$ and is concave up on the interval $(e^{16/15}, \infty)$.

- (b) Because the concavity of f changes at $e^{16/15}$, the point $(e^{16/15}, f(e^{16/15})) = \left(e^{16/15}, \frac{16}{15e^{8/5}}\right)$ is a point of inflection of f .
49. Let $f(x) = x + \frac{1}{x}$.
- (a) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,
- $$f'(x) = 1 - \frac{1}{x^2} \quad \text{and} \quad f''(x) = \frac{2}{x^3},$$
- so $f''(x)$ exists on the domain of f , the set $\{x|x \neq 0\}$, and is never equal to 0. When $x < 0$, $f''(x) < 0$ and when $x > 0$, $f''(x) > 0$. Therefore, f is concave down on the interval $(-\infty, 0)$ and concave up on the interval $(0, \infty)$.
- (b) Note that f does not have a point of inflection at 0 because f is not defined at 0. Therefore, f has no points of inflection.
50. Let $f(x) = 2x^2 - \frac{1}{x}$.
- (a) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,
- $$f'(x) = 4x + \frac{1}{x^2} \quad \text{and} \quad f''(x) = 4 - \frac{2}{x^3},$$
- so $f''(x)$ exists on the domain of f , the set $\{x|x \neq 0\}$, and $f''(x) = 0$ when $x = \frac{1}{\sqrt[3]{2}}$. When $x < 0$, $f''(x) > 0$; when $0 < x < \frac{1}{\sqrt[3]{2}}$, $f''(x) < 0$; and when $x > \frac{1}{\sqrt[3]{2}}$, $f''(x) > 0$. Therefore, f is concave up on the intervals $(-\infty, 0)$ and $\left(\frac{1}{\sqrt[3]{2}}, \infty\right)$ and concave down on the interval $\left(0, \frac{1}{\sqrt[3]{2}}\right)$.
- (b) Because the concavity of f changes at $\frac{1}{\sqrt[3]{2}}$, the point $\left(\frac{1}{\sqrt[3]{2}}, f\left(\frac{1}{\sqrt[3]{2}}\right)\right) = \left(\frac{1}{\sqrt[3]{2}}, 0\right)$ is a point of inflection of f . Note that f does not have a point of inflection at 0 because f is not defined at 0. Therefore, f has no points of inflection.
51. Let $f(x) = 3x^{1/3} + 2x$.
- (a) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,
- $$f'(x) = x^{-2/3} + 2 \quad \text{and} \quad f''(x) = -\frac{2}{3}x^{-5/3},$$
- so $f''(x)$ does not exist at $x = 0$ and is never equal to 0. When $x < 0$, $f''(x) > 0$ and when $x > 0$, $f''(x) < 0$. Therefore, f is concave up on the interval $(-\infty, 0)$ and concave down on the interval $(0, \infty)$.
- (b) Because the concavity of f changes at 0, the point $(0, f(0)) = (0, 0)$ is a point of inflection of f .
52. Let $f(x) = x^{4/3} - 8x^{1/3}$.
- (a) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,
- $$f'(x) = \frac{4}{3}x^{1/3} - \frac{8}{3}x^{-2/3} \quad \text{and} \quad f''(x) = \frac{4}{9}x^{-2/3} + \frac{16}{9}x^{-5/3} = \frac{4x + 16}{9x^{5/3}},$$
- so $f''(x)$ does not exist at $x = 0$ and $f''(x) = 0$ when $x = -4$. To determine where $f''(x) > 0$ and $f''(x) < 0$, use the numbers -4 and 0 to divide the number line into three intervals. The sign of $f''(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $4x + 32$	Sign of $9x^{5/3}$	Sign of $f''(x)$	Conclusion
$(-\infty, -4)$	—	—	+	f is concave up
$(-4, 0)$	+	—	—	f is concave down
$(0, \infty)$	+	+	+	f is concave up

Therefore, f is concave up on the intervals $(-\infty, -4)$ and $(0, \infty)$ and concave down on the interval $(-4, 0)$.

- (b) Because the concavity of f changes at -4 and 0 , the points $(-4, f(-4)) = (-4, 12\sqrt[3]{4})$ and $(0, f(0)) = (0, 0)$ are points of inflection of f .

53. Let $f(x) = 3 - \frac{4}{x} + \frac{4}{x^2}$.

- (a) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f'(x) = \frac{4}{x^2} - \frac{8}{x^3} \quad \text{and} \quad f''(x) = -\frac{8}{x^3} + \frac{24}{x^4} = \frac{24 - 8x}{x^4},$$

so $f''(x)$ exists on the domain of f , the set $\{x | x \neq 0\}$, and $f''(x) = 0$ when $x = 3$. To determine where $f''(x) > 0$ and $f''(x) < 0$, use the numbers 0 and 3 to divide the number line into three intervals. The sign of $f''(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $24 - 8x$	Sign of x^4	Sign of $f''(x)$	Conclusion
$(-\infty, 0)$	+	+	+	f is concave up
$(0, 3)$	+	+	+	f is concave up
$(3, \infty)$	—	+	—	f is concave down

Therefore, f is concave up on the intervals $(-\infty, 0)$ and $(0, 3)$ and concave down on the interval $(3, \infty)$.

- (b) Because the concavity of f changes at 3 , the point $(3, f(3)) = \left(3, \frac{19}{9}\right)$ is a point of inflection of f .

54. Let $f(x) = (x - 1)^{3/2}$.

- (a) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f'(x) = \frac{3}{2}(x - 1)^{1/2} \quad \text{and} \quad f''(x) = \frac{3}{4}(x - 1)^{-1/2},$$

so $f''(x)$ does not exist at $x = 1$ and is never equal to zero. When $x > 1$, $f''(x) > 0$, so f is concave up on the interval $(1, \infty)$.

- (b) Because the concavity of f does not change, f has no points of inflection.

55. Let $f(x) = 2x^3 - 6x^2 + 6x - 3$.

- (a) The polynomial function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = 6x^2 - 12x + 6 = 6(x^2 - 2x + 1) = 6(x - 1)^2,$$

so 1 is a critical number of f . For $x \neq 1$, $f'(x) > 0$, so that f is increasing on the intervals $(-\infty, 1)$ and $(1, \infty)$. By the First Derivative Test, it follows that f has neither a local maximum value nor a local minimum value at 1. Hence, f has no local extrema.

- (b) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f''(x) = 12x - 12 = 12(x - 1).$$

For $x < 1$, $f''(x) < 0$, and for $x > 1$, $f''(x) > 0$. Therefore, f is concave down on the interval $(-\infty, 1)$ and concave up on the interval $(1, \infty)$.

- (c) Because the concavity of f changes at 1, the point $(1, f(1)) = (1, -1)$ is a point of inflection of f .

56. Let $f(x) = 2x^3 + 9x^2 + 12x - 4$.

- (a) The polynomial function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = 6x^2 + 18x + 12 = 6(x^2 + 3x + 2) = 6(x + 1)(x + 2),$$

so -2 and -1 are critical numbers of f . To determine where $f'(x) > 0$ and $f'(x) < 0$, use the numbers -2 and -1 to divide the number line into three intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $6(x + 1)$	Sign of $x + 2$	Sign of $f'(x)$	Conclusion
$(-\infty, -2)$	—	—	+	f is increasing
$(-2, -1)$	—	+	—	f is decreasing
$(-1, \infty)$	+	+	+	f is increasing

Therefore, f is increasing on the intervals $(-\infty, -2)$ and $(-1, \infty)$ and decreasing on the interval $(-2, -1)$. By the First Derivative Test, it follows that f has a local maximum value at -2 and a local minimum value at -1 . The local maximum value is $f(-2) = -8$, and the local minimum value is $f(-1) = -9$.

- (b) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f''(x) = 12x + 18 = 6(2x + 3).$$

For $x < -\frac{3}{2}$, $f''(x) < 0$, and for $x > -\frac{3}{2}$, $f''(x) > 0$. Therefore, f is concave down on the interval $(-\infty, -\frac{3}{2})$ and concave up on the interval $(-\frac{3}{2}, \infty)$.

- (c) Because the concavity of f changes at $-\frac{3}{2}$, the point $(-\frac{3}{2}, f(-\frac{3}{2})) = (-\frac{3}{2}, -\frac{17}{2})$ is a point of inflection of f .

57. Let $f(x) = x^4 - 4x$.

- (a) The polynomial function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = 4x^3 - 4 = 4(x^3 - 1) = 4(x - 1)(x^2 + x + 1),$$

so 1 is a critical number of f . For $x < 1$, $f'(x) < 0$, so f is decreasing on the interval $(-\infty, 1)$; for $x > 1$, $f'(x) > 0$, so f is increasing on the interval $(1, \infty)$. By the First Derivative Test, it follows that f has a local minimum value at 1. The local minimum value is $f(1) = -3$.

- (b) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f''(x) = 12x^2,$$

so $f''(x) > 0$ for $x \neq 0$. Therefore, f is concave up on the intervals $(-\infty, 0)$ and $(0, \infty)$.

- (c) Because the concavity of f never changes, f has no points of inflection.

58. Let $f(x) = x^4 + 4x$.

- (a) The polynomial function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = 4x^3 + 4 = 4(x^3 + 1) = 4(x + 1)(x^2 - x + 1),$$

so -1 is a critical number of f . For $x < -1$, $f'(x) < 0$, so f is decreasing on the interval $(-\infty, -1)$; for $x > -1$, $f'(x) > 0$, so f is increasing on the interval $(-1, \infty)$. By the First Derivative Test, it follows that f has a local minimum value at -1 . The local minimum value is $f(-1) = -3$.

- (b) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f''(x) = 12x^2,$$

so $f''(x) > 0$ for $x \neq 0$. Therefore, f is concave up on the intervals $(-\infty, 0)$ and $(0, \infty)$.

- (c) Because the concavity of f never changes, f has no points of inflection.

59. Let $f(x) = 5x^4 - x^5$.

- (a) The polynomial function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = 20x^3 - 5x^4 = 5x^3(4 - x),$$

so 0 and 4 are critical numbers of f . To determine where $f'(x) > 0$ and $f'(x) < 0$, use the numbers 0 and 4 to divide the number line into three intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $5x^3$	Sign of $4 - x$	Sign of $f'(x)$	Conclusion
$(-\infty, 0)$	—	+	—	f is decreasing
$(0, 4)$	+	+	+	f is increasing
$(4, \infty)$	+	—	—	f is decreasing

Therefore, f is decreasing on the intervals $(-\infty, 0)$ and $(4, \infty)$ and increasing on the interval $(0, 4)$. By the First Derivative Test, it follows that f has a local minimum value at 0 and a local maximum value at 4. The local minimum value is $f(0) = 0$, and the local maximum value is $f(4) = 256$.

- (b) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f''(x) = 60x^2 - 20x^3 = 20x^2(3 - x),$$

so $f''(x) = 0$ when $x = 0$ and when $x = 3$. To determine where $f''(x) > 0$ and $f''(x) < 0$, use the numbers 0 and 3 to divide the number line into three intervals. The sign of $f''(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $20x^2$	Sign of $3 - x$	Sign of $f''(x)$	Conclusion
$(-\infty, 0)$	+	+	+	f is concave up
$(0, 3)$	+	+	+	f is concave up
$(3, \infty)$	+	—	—	f is concave down

Therefore, f is concave up on the intervals $(-\infty, 0)$ and $(0, 3)$ and concave down on the interval $(3, \infty)$.

- (c) Because the concavity of f changes at 3, the point $(3, f(3)) = (3, 162)$ is a point of inflection of f .

60. Let $f(x) = 4x^6 + 6x^4$.

- (a) The polynomial function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = 24x^5 + 24x^3 = 24x^3(x^2 + 1),$$

so 0 is a critical number of f . For $x < 0$, $f'(x) < 0$, so f is decreasing on the interval $(-\infty, 0)$; for $x > 0$, $f'(x) > 0$, so f is increasing on the interval $(0, \infty)$. By the First Derivative Test, it follows that f has a local minimum value at 0. The local minimum value is $f(0) = 0$.

- (b) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f''(x) = 120x^4 + 72x^2 = 24x^2(5x^2 + 3),$$

so $f''(x) = 0$ when $x = 0$. For $x \neq 0$, $f''(x) > 0$, so f is

concave up on the intervals $(-\infty, 0)$ and $(0, \infty)$.

- (c) Because the concavity of f never changes, f has no points of inflection.

61. Let $f(x) = 3x^5 - 20x^3$.

- (a) The polynomial function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = 15x^4 - 60x^2 = 15x^2(x^2 - 4) = 15x^2(x - 2)(x + 2),$$

so -2 , 0 , and 2 are critical numbers of f . To determine where $f'(x) > 0$ and $f'(x) < 0$, use the numbers -2 , 0 , and 2 to divide the number line into four intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $15x^2$	Sign of $x - 2$	Sign of $x + 2$	Sign of $f'(x)$	Conclusion
$(-\infty, -2)$	+	−	−	+	f is increasing
$(-2, 0)$	+	−	+	−	f is decreasing
$(0, 2)$	+	−	+	−	f is decreasing
$(2, \infty)$	+	+	+	+	f is increasing

Therefore, f is increasing on the intervals $(-\infty, -2)$ and $(2, \infty)$ and decreasing on the intervals $(-2, 0)$ and $(0, 2)$. By the First Derivative Test, it follows that f has a local maximum value at -2 , neither a local maximum value nor a local minimum value at 0 , and a local minimum value at 2 . The local maximum value is $f(-2) = 64$, and the local minimum value is $f(2) = -64$.

- (b) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f''(x) = 60x^3 - 120x = 60x(x^2 - 2) = 60x(x - \sqrt{2})(x + \sqrt{2}),$$

so $f''(x) = 0$ when $x = \pm\sqrt{2}$ and when $x = 0$. To determine where $f''(x) > 0$ and $f''(x) < 0$, use the numbers $-\sqrt{2}$, 0 , and $\sqrt{2}$ to divide the number line into four intervals. The sign of $f''(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $60x$	Sign of $x - \sqrt{2}$	Sign of $x + \sqrt{2}$	Sign of $f''(x)$	Conclusion
$(-\infty, -\sqrt{2})$	-	-	-	-	f is concave down
$(-\sqrt{2}, 0)$	-	-	+	+	f is concave up
$(0, \sqrt{2})$	+	-	+	-	f is concave down
$(\sqrt{2}, \infty)$	+	+	+	+	f is concave up

Therefore, f is concave up on the intervals $(-\sqrt{2}, 0)$ and $(\sqrt{2}, \infty)$ and concave down on the intervals $(-\infty, -\sqrt{2})$ and $(0, \sqrt{2})$.

- (c) Because the concavity of f changes at $-\sqrt{2}$, 0 , and $\sqrt{2}$, the points $(-\sqrt{2}, f(-\sqrt{2})) = (-\sqrt{2}, 28\sqrt{2})$, $(0, f(0)) = (0, 0)$, and $(\sqrt{2}, f(\sqrt{2})) = (\sqrt{2}, -28\sqrt{2})$ are points of inflection of f .

62. Let $f(x) = 3x^5 + 5x^3$.

- (a) The polynomial function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = 15x^4 + 15x^2 = 15x^2(x^2 + 1),$$

so 0 is a critical number of f . For $x \neq 0$, $f'(x) > 0$, so f is increasing on the intervals $(-\infty, 0)$ and $(0, \infty)$. By the First Derivative Test, it follows that f has neither a local maximum value nor a local minimum value at 0 . Hence, f has no local extrema.

- (b) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f''(x) = 60x^3 + 30x = 30x(2x^2 + 1),$$

so $f''(x) = 0$ when $x = 0$. For $x < 0$, $f''(x) < 0$, so f is concave down on the interval $(-\infty, 0)$; for $x > 0$, $f''(x) > 0$, so f is concave up on the interval $(0, \infty)$.

- (c) Because the concavity of f changes at 0 , the point $(0, f(0)) = (0, 0)$ is a point of inflection of f .

63. Let $f(x) = x^2e^x$.

- (a) The function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = x^2e^x + 2xe^x = xe^x(x + 2),$$

so -2 and 0 are critical numbers of f . To determine where $f'(x) > 0$ and $f'(x) < 0$, use the numbers -2 and 0 to divide the number line into three intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of xe^x	Sign of $x + 2$	Sign of $f'(x)$	Conclusion
$(-\infty, -2)$	-	-	+	f is increasing
$(-2, 0)$	-	+	-	f is decreasing
$(0, \infty)$	+	+	+	f is increasing

Therefore, f is increasing on the intervals $(-\infty, -2)$ and $(0, \infty)$ and decreasing on the interval $(-2, 0)$. By the First Derivative Test, it follows that f has a local maximum value at -2 and a local minimum value at 0 . The local maximum value is $f(-2) = 4e^{-2}$, and the local minimum value is $f(0) = 0$.

- (b) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f''(x) = (x^2 + 2x)e^x + (2x + 2)e^x = e^x(x^2 + 4x + 2) = e^x[(x + 2)^2 - 2],$$

so $f''(x) = 0$ when $x = -2 \pm \sqrt{2}$. To determine where $f''(x) > 0$ and $f''(x) < 0$, use the numbers $-2 - \sqrt{2}$ and $-2 + \sqrt{2}$ to divide the number line into three intervals. The sign of $f''(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of e^x	Sign of $x^2 + 4x + 2$	Sign of $f''(x)$	Conclusion
$(-\infty, -2 - \sqrt{2})$	+	+	+	f is concave up
$(-2 - \sqrt{2}, -2 + \sqrt{2})$	+	-	-	f is concave down
$(-2 + \sqrt{2}, \infty)$	+	+	+	f is concave up

Therefore, f is concave up on the intervals $(-\infty, -2 - \sqrt{2})$ and $(-2 + \sqrt{2}, \infty)$ and concave down on the interval $(-2 - \sqrt{2}, -2 + \sqrt{2})$.

- (c) Because the concavity of f changes at $-2 - \sqrt{2}$ and $-2 + \sqrt{2}$, the points

$$(-2 - \sqrt{2}, f(-2 - \sqrt{2})) = (-2 - \sqrt{2}, (6 + 4\sqrt{2})e^{-2-\sqrt{2}})$$

and

$$(-2 + \sqrt{2}, f(-2 + \sqrt{2})) = (-2 + \sqrt{2}, (6 - 4\sqrt{2})e^{-2+\sqrt{2}})$$

are points of inflection of f .

64. Let $f(x) = x^3e^x$.

- (a) The function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = x^3e^x + 3x^2e^x = x^2e^x(x + 3),$$

so -3 and 0 are critical numbers of f . To determine where $f'(x) > 0$ and $f'(x) < 0$, use the numbers -3 and 0 to divide the number line into three intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of x^2e^x	Sign of $x + 3$	Sign of $f'(x)$	Conclusion
$(-\infty, -3)$	+	-	-	f is decreasing
$(-3, 0)$	+	+	+	f is increasing
$(0, \infty)$	+	+	+	f is increasing

Therefore, f is decreasing on the interval $(-\infty, -3)$ and increasing on the intervals $(-3, 0)$ and $(0, \infty)$. By the First Derivative Test, it follows that f has a local minimum value at -3 and neither a local maximum value nor a local minimum value at 0 . The local minimum value is $f(-3) = -27e^{-3}$.

- (b) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f''(x) = (x^3 + 3x^2)e^x + (3x^2 + 6x)e^x = xe^x(x^2 + 6x + 6) = xe^x[(x + 3)^2 - 3],$$

so $f''(x) = 0$ when $x = -3 \pm \sqrt{3}$ and when $x = 0$. To determine where $f''(x) > 0$ and $f''(x) < 0$, use the numbers $-3 - \sqrt{3}$, $-3 + \sqrt{3}$, and 0 to divide the number line into four intervals. The sign of $f''(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of xe^x	Sign of $x^2 + 6x + 6$	Sign of $f''(x)$	Conclusion
$(-\infty, -3 - \sqrt{3})$	-	+	-	f is concave down
$(-3 - \sqrt{3}, -3 + \sqrt{3})$	-	-	+	f is concave up
$(-3 + \sqrt{3}, 0)$	-	+	-	f is concave down
$(0, \infty)$	+	+	+	f is concave up

Therefore, f is concave down on the intervals $(-\infty, -3 - \sqrt{3})$ and $(-3 + \sqrt{3}, 0)$ and concave up on the intervals $(-3 - \sqrt{3}, -3 + \sqrt{3})$ and $(0, \infty)$.

- (c) Because the concavity of f changes at $-3 - \sqrt{3}$, $-3 + \sqrt{3}$, and 0 , the points

$$\boxed{(-3 - \sqrt{3}, f(-3 - \sqrt{3})) = (-3 - \sqrt{3}, -(54 + 30\sqrt{3})e^{-3-\sqrt{3}})},$$

$$\boxed{(-3 + \sqrt{3}, f(-3 + \sqrt{3})) = (-3 + \sqrt{3}, (30\sqrt{3} - 54)e^{-3+\sqrt{3}})},$$

and $(0, f(0)) = (0, 0)$ are points of inflection of f .

65. Let $f(x) = \frac{e^x + e^{-x}}{2} = \cosh x$.

- (a) The function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = \sinh x,$$

so 0 is a critical number of f . For $x < 0$, $f'(x) < 0$, so f is decreasing on the interval $(-\infty, 0)$; for $x > 0$, $f'(x) > 0$, so f is increasing on the interval $(0, \infty)$. By the First Derivative Test, it follows that f has a local minimum value at 0 . The local minimum value is $f(0) = \cosh 0 = 1$.

- (b) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f''(x) = \cosh x \geq 1 > 0$$

for all x . Therefore, f is concave up on the interval $(-\infty, \infty)$.

- (c) Because the concavity of f does not change, f has no points of inflection.

66. Let $f(x) = \frac{e^x - e^{-x}}{2} = \sinh x$.

- (a) The function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = \cosh x \geq 1 > 0$$

for all x , so f is increasing on the interval $(-\infty, \infty)$. Because f has no critical numbers, f has no local extrema.

- (b) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f''(x) = \sinh x,$$

so $f''(x) = 0$ when $x = 0$. For $x < 0$, $f''(x) < 0$, so f is concave down on the interval $(-\infty, 0)$; for $x > 0$, $f''(x) > 0$, so f is concave up on the interval $(0, \infty)$.

- (c) Because the concavity of f changes at 0 , the point $(0, f(0)) = (0, 0)$ is a point of inflection of f .

67. Let $f(x) = 6x^{4/3} - 3x^{1/3}$.

(a) The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now,

$$f'(x) = 8x^{1/3} - x^{-2/3} = \frac{8x - 1}{x^{2/3}},$$

so 0 and $\frac{1}{8}$ are critical numbers. To determine where $f'(x) > 0$ and $f'(x) < 0$, use the numbers 0 and $\frac{1}{8}$ to divide the number line into three intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $8x - 1$	Sign of $x^{2/3}$	Sign of $f'(x)$	Conclusion
$(-\infty, 0)$	-	+	-	f is decreasing
$(0, \frac{1}{8})$	-	+	-	f is decreasing
$(\frac{1}{8}, \infty)$	+	+	+	f is increasing

Therefore, f is decreasing on the intervals $(-\infty, 0)$ and $(0, \frac{1}{8})$ and increasing on the interval $(\frac{1}{8}, \infty)$. By the First Derivative Test, f has neither a local maximum value nor a local minimum

value at 0 and a local minimum value at $\frac{1}{8}$. The local minimum value is $f\left(\frac{1}{8}\right) = -\frac{9}{8}$.

(b) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f''(x) = \frac{8}{3}x^{-2/3} + \frac{2}{3}x^{-5/3} = \frac{8x + 2}{3x^{5/3}},$$

so $f''(x) = 0$ when $x = -\frac{1}{4}$ and $f''(x)$ does not exist when $x = 0$. To determine where $f''(x) > 0$ and $f''(x) < 0$, use the numbers $-\frac{1}{4}$ and 0 to divide the number line into three intervals. The sign of $f''(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $8x + 2$	Sign of $3x^{5/3}$	Sign of $f''(x)$	Conclusion
$(-\infty, -\frac{1}{4})$	-	-	+	f is concave up
$(-\frac{1}{4}, 0)$	+	-	-	f is concave down
$(0, \infty)$	+	+	+	f is concave up

Therefore, f is concave up on the intervals $(-\infty, -\frac{1}{4})$ and $(0, \infty)$ and

concave down on the interval $(-\frac{1}{4}, 0)$.

(c) Because the concavity of f changes at $-\frac{1}{4}$ and 0, the points $\left(-\frac{1}{4}, f\left(-\frac{1}{4}\right)\right) = \left(-\frac{1}{4}, \frac{9\sqrt[3]{2}}{4}\right)$

and $(0, f(0)) = (0, 0)$ are points of inflection of f .

68. Let $f(x) = x^{2/3} - x^{1/3}$.

- (a) The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now,

$$f'(x) = \frac{2}{3}x^{-1/3} - \frac{1}{3}x^{-2/3} = \frac{2x^{1/3} - 1}{3x^{2/3}},$$

so 0 and $\frac{1}{8}$ are critical numbers of f . To determine where $f'(x) > 0$ and $f'(x) < 0$, use the numbers 0 and $\frac{1}{8}$ to divide the number line into three intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $2x^{1/3} - 1$	Sign of $x^{2/3}$	Sign of $f'(x)$	Conclusion
$(-\infty, 0)$	—	+	—	f is decreasing
$(0, \frac{1}{8})$	—	+	—	f is decreasing
$(\frac{1}{8}, \infty)$	+	+	+	f is increasing

Therefore, f is decreasing on the intervals $(-\infty, 0)$ and $(0, \frac{1}{8})$ and increasing on the interval $(\frac{1}{8}, \infty)$. By the First Derivative Test, f has neither a local maximum value nor a local minimum

value at 0 and a local minimum value at $\frac{1}{8}$. The local minimum value is $f\left(\frac{1}{8}\right) = -\frac{1}{4}$.

- (b) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f''(x) = -\frac{2}{9}x^{-4/3} + \frac{2}{9}x^{-5/3} = \frac{2}{9} \frac{1 - x^{1/3}}{x^{5/3}},$$

so $f''(x) = 0$ when $x = 1$ and $f''(x)$ does not exist when $x = 0$. To determine where $f''(x) > 0$ and $f''(x) < 0$, use the numbers 0 and 1 to divide the number line into three intervals. The sign of $f''(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $\frac{2}{9}(1 - x^{1/3})$	Sign of $x^{5/3}$	Sign of $f''(x)$	Conclusion
$(-\infty, 0)$	+	—	—	f is concave down
$(0, 1)$	+	+	+	f is concave up
$(1, \infty)$	—	+	—	f is concave down

Therefore, f is concave down on the intervals $(-\infty, 0)$ and $(1, \infty)$ and concave up on the interval $(0, 1)$.

- (c) Because the concavity of f changes at 0 and 1, the points $(0, f(0)) = (0, 0)$ and $(1, f(1)) = (1, 0)$ are points of inflection of f .

69. Let $f(x) = x^{2/3}(x^2 - 8)$.

- (a) The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now,

$$f'(x) = x^{2/3}(2x) + (x^2 - 8) \cdot \frac{2}{3}x^{-1/3} = \frac{6x^2 + 2(x^2 - 8)}{3x^{1/3}} = \frac{8(x - \sqrt{2})(x + \sqrt{2})}{3x^{1/3}},$$

so 0 and $\pm\sqrt{2}$ are critical numbers of f . To determine where $f'(x) > 0$ and $f'(x) < 0$, use the numbers 0 and $\pm\sqrt{2}$ to divide the number line into four intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $8(x - \sqrt{2})$	Sign of $x + \sqrt{2}$	Sign of $3x^{1/3}$	Sign of $f'(x)$	Conclusion
$(-\infty, -\sqrt{2})$	—	—	—	—	f is decreasing
$(-\sqrt{2}, 0)$	—	+	—	+	f is increasing
$(0, \sqrt{2})$	—	+	+	—	f is decreasing
$(\sqrt{2}, \infty)$	+	+	+	+	f is increasing

Therefore, f is decreasing on the intervals $(-\infty, -\sqrt{2})$ and $(0, \sqrt{2})$ and increasing on the intervals $(-\sqrt{2}, 0)$ and $(\sqrt{2}, \infty)$. By the First Derivative Test, it follows that f has local minimum values at $-\sqrt{2}$ and $\sqrt{2}$ and a local maximum value at 0. The

$$\text{local minimum values are } f(-\sqrt{2}) = -6\sqrt[3]{2} \text{ and } f(\sqrt{2}) = -6\sqrt[3]{2},$$

and the local maximum value is $f(0) = 0$.

- (b) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f''(x) = \frac{3x^{1/3}(16x) - 8(x^2 - 2) \cdot x^{-2/3}}{9x^{2/3}} = \frac{40x^2 + 16}{9x^{4/3}},$$

so $f''(x)$ does not exist when $x = 0$ and is never equal to zero. For $x \neq 0$, $f''(x) > 0$, so f is concave up on the intervals $(-\infty, 0)$ and $(0, \infty)$.

- (c) Because the concavity of f does not change, f has no points of inflection.

70. Let $f(x) = x^{1/3}(x^2 - 2)$.

- (a) The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now,

$$f'(x) = x^{1/3}(2x) + (x^2 - 2) \cdot \frac{1}{3}x^{-2/3} = \frac{6x^2 + x^2 - 2}{3x^{2/3}} = \frac{7x^2 - 2}{3x^{2/3}},$$

so 0 and $\pm \frac{2\sqrt{7}}{7}$ are critical numbers of f . To determine where $f'(x) > 0$ and $f'(x) < 0$, use the numbers 0 and $\pm \frac{2\sqrt{7}}{7}$ to divide the number line into four intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $7x^2 - 2$	Sign of $3x^{2/3}$	Sign of $f'(x)$	Conclusion
$(-\infty, -\frac{2\sqrt{7}}{7})$	+	+	+	f is increasing
$(-\frac{2\sqrt{7}}{7}, 0)$	—	+	—	f is decreasing
$(0, \frac{2\sqrt{7}}{7})$	—	+	—	f is decreasing
$(\frac{2\sqrt{7}}{7}, \infty)$	+	+	+	f is increasing

Therefore, f is increasing on the intervals $(-\infty, -\frac{2\sqrt{7}}{7})$ and $(\frac{2\sqrt{7}}{7}, \infty)$ and decreasing on the intervals $(-\frac{2\sqrt{7}}{7}, 0)$ and $(0, \frac{2\sqrt{7}}{7})$. By the First Derivative Test, f has a local maximum value at $-\frac{2\sqrt{7}}{7}$, neither a local maximum value nor a local minimum value at 0, and a local minimum

value at $\frac{2\sqrt{7}}{7}$. The local maximum value is

$$f\left(-\frac{2\sqrt{7}}{7}\right) = \left(-\frac{2\sqrt{7}}{7}\right)^{1/3} \left(\frac{2}{7} - 2\right) \approx 1.562,$$

and the local minimum value is

$$f\left(\frac{2\sqrt{7}}{7}\right) = \left(\frac{2\sqrt{7}}{7}\right)^{1/3} \left(\frac{2}{7} - 2\right) \approx -1.562.$$

- (b) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f''(x) = \frac{3x^{2/3}(14x) - 2(7x^2 - 2) \cdot x^{-1/3}}{9x^{4/3}} = \frac{28x^2 + 4}{9x^{5/3}},$$

so $f''(x)$ does not exist when $x = 0$ and is never equal to zero. For $x < 0$, $f''(x) < 0$, so f is concave down on the interval $(-\infty, 0)$; for $x > 0$, $f''(x) > 0$, so f is concave up on the interval $(0, \infty)$.

- (c) Because the concavity of f changes at 0, the point $(0, f(0)) = (0, 0)$ is a point of inflection of f .

71. Let $f(x) = x^2 - \ln x$. Note that the domain of f is the set $\{x|x > 0\}$.

- (a) The function f is differentiable on its domain, so critical numbers occur where $f'(x) = 0$. Now,

$$f'(x) = 2x - \frac{1}{x} = \frac{2x^2 - 1}{x},$$

so $\frac{\sqrt{2}}{2}$ is a critical number of f . For $0 < x < \frac{\sqrt{2}}{2}$, $f'(x) < 0$, so f is decreasing on the interval $\left(0, \frac{\sqrt{2}}{2}\right)$; for $x > \frac{\sqrt{2}}{2}$, $f'(x) > 0$, so f is increasing on the interval $\left(\frac{\sqrt{2}}{2}, \infty\right)$. By the First Derivative Test, it follows that f has a local minimum value at $\frac{\sqrt{2}}{2}$. The

$$\text{local minimum value is } f\left(\frac{\sqrt{2}}{2}\right) = \frac{1}{2} + \frac{1}{2} \ln 2.$$

- (b) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f''(x) = 2 + \frac{1}{x^2} > 2 > 0$$

for all $x > 0$. Therefore, f is concave up on the interval $(0, \infty)$.

- (c) Because the concavity of f does not change, f has no points of inflection.

72. Let $f(x) = \ln x - x$. Note that the domain of f is the set $\{x|x > 0\}$.

- (a) The function f is differentiable on its domain, so critical numbers occur where $f'(x) = 0$. Now,

$$f'(x) = \frac{1}{x} - 1 = \frac{1-x}{x},$$

so 1 is a critical number of f . For $0 < x < 1$, $f'(x) > 0$, so f is increasing on the interval $(0, 1)$; for $x > 1$, $f'(x) < 0$, so f is decreasing on the interval $(1, \infty)$. By the First Derivative Test, it follows that f has a local maximum value at 1. The local minimum value is $f(1) = -1$.

(b) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f''(x) = -\frac{1}{x^2} < 0$$

for all $x > 0$. Therefore, f is concave down on the interval $(0, \infty)$.

(c) Because the concavity of f does not change, f has no points of inflection.

73. Let $f(x) = \frac{x}{(1+x^2)^{5/2}}$.

(a) The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now,

$$f'(x) = \frac{(1+x^2)^{5/2} - x \cdot \frac{5}{2}(1+x^2)^{3/2}(2x)}{(1+x^2)^5} = \frac{1-4x^2}{(1+x^2)^{7/2}} = \frac{(1-2x)(1+2x)}{(1+x^2)^{7/2}},$$

so $\pm \frac{1}{2}$ are critical numbers of f . To determine where $f'(x) > 0$ and $f'(x) < 0$, use the numbers $\pm \frac{1}{2}$ to divide the number line into three intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $1-2x$	Sign of $1+2x$	Sign of $(1+x^2)^{7/2}$	Sign of $f'(x)$	Conclusion
$(-\infty, -\frac{1}{2})$	+	-	+	-	f is decreasing
$(-\frac{1}{2}, \frac{1}{2})$	+	+	+	+	f is increasing
$(\frac{1}{2}, \infty)$	-	+	+	-	f is decreasing

Therefore, f is decreasing on the intervals $(-\infty, -\frac{1}{2})$ and $(\frac{1}{2}, \infty)$ and increasing on the interval $(-\frac{1}{2}, \frac{1}{2})$. By the First Derivative Test, it follows that f has a local minimum value at $-\frac{1}{2}$ and a

local maximum value at $\frac{1}{2}$. The local minimum value is $f\left(-\frac{1}{2}\right) = -\frac{16}{5^{5/2}} = -\frac{16\sqrt{5}}{125}$, and the

local maximum value is $f\left(\frac{1}{2}\right) = \frac{16}{5^{5/2}} = \frac{16\sqrt{5}}{125}$.

(b) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$\begin{aligned} f''(x) &= \frac{(1+x^2)^{7/2}(-8x) - (1-4x^2) \cdot \frac{7}{2}(1+x^2)^{5/2}(2x)}{(1+x^2)^7} \\ &= \frac{-8x - 8x^3 - 7x + 28x^3}{(1+x^2)^{9/2}} = \frac{5x(4x^2-3)}{(1+x^2)^{9/2}}, \end{aligned}$$

so $f''(x)$ exists for all x and is equal to zero when $x = 0$ and when $x = \pm \frac{\sqrt{3}}{2}$. To determine where $f''(x) > 0$ and $f''(x) < 0$, use the numbers 0 and $\pm \frac{\sqrt{3}}{2}$ to divide the number line into four intervals. The sign of $f''(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $5x$	Sign of $4x^2 - 3$	Sign of $(1 + x^2)^{9/2}$	Sign of $f''(x)$	Conclusion
$\left(-\infty, -\frac{\sqrt{3}}{2}\right)$	-	+	+	-	f is concave down
$\left(-\frac{\sqrt{3}}{2}, 0\right)$	-	-	+	+	f is concave up
$\left(0, \frac{\sqrt{3}}{2}\right)$	+	-	+	-	f is concave down
$\left(\frac{\sqrt{3}}{2}, \infty\right)$	+	+	+	+	f is concave up

Therefore, f is concave down on the intervals $\left(-\infty, -\frac{\sqrt{3}}{2}\right)$ and $\left(0, \frac{\sqrt{3}}{2}\right)$ and concave up on the intervals $\left(-\frac{\sqrt{3}}{2}, 0\right)$ and $\left(\frac{\sqrt{3}}{2}, \infty\right)$.

(c) Because the concavity of f changes at $\pm\frac{\sqrt{3}}{2}$ and 0, the points

$$\left(-\frac{\sqrt{3}}{2}, f\left(-\frac{\sqrt{3}}{2}\right)\right) = \left(-\frac{\sqrt{3}}{2}, -\frac{16\sqrt{3}}{7^{5/2}}\right),$$

$$\left(\frac{\sqrt{3}}{2}, f\left(\frac{\sqrt{3}}{2}\right)\right) = \left(\frac{\sqrt{3}}{2}, \frac{16\sqrt{3}}{7^{5/2}}\right),$$

and $(0, f(0)) = (0, 0)$ are points of inflection of f .

74. Let $f(x) = \frac{\sqrt{x}}{1+x}$. Note that the domain of f is the set $\{x|x \geq 0\}$.

(a) The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now,

$$f'(x) = \frac{(1+x) \cdot \frac{1}{2\sqrt{x}} - \sqrt{x} \cdot 1}{(1+x)^2} = \frac{1+x-2x}{2\sqrt{x}(1+x)^2} = \frac{1-x}{2\sqrt{x}(1+x)^2},$$

so 0 and 1 are critical numbers of f . For $0 < x < 1$, $f'(x) > 0$, so f is increasing on the interval $(0, 1)$; for $x > 1$, $f'(x) < 0$, so f is decreasing on the interval $(1, \infty)$. By the First Derivative Test,

it follows that f has a local maximum value at 1. The local maximum value is $f(1) = \frac{1}{2}$.

(b) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$\begin{aligned} f''(x) &= \frac{2\sqrt{x}(1+x)^2 \cdot (-1) - (1-x) \left[4\sqrt{x}(1+x) + \frac{1}{\sqrt{x}}(1+x)^2\right]}{4x(1+x)^4} \\ &= \frac{-2x - 2x^2 - 5x - 1 + 5x^2 + x}{4x^{3/2}(1+x)^3} = \frac{3x^2 - 6x - 1}{4x^{3/2}(1+x)^3}, \end{aligned}$$

so $f''(x)$ does not exist when $x = 0$ and $f''(x) = 0$ when

$$x = \frac{6 \pm \sqrt{36 - 4(3)(-1)}}{6} = \frac{6 \pm 4\sqrt{3}}{6} = 1 \pm \frac{2\sqrt{3}}{3}.$$

Note that $1 - \frac{2\sqrt{3}}{3} \approx -1.15 < 0$ is not in the domain of f , so this number may be excluded.

For $0 < x < 1 + \frac{2\sqrt{3}}{3}$, $f''(x) < 0$, so f is concave down on the interval $\left(0, 1 + \frac{2\sqrt{3}}{3}\right)$; for

$x > 1 + \frac{2\sqrt{3}}{3}$, $f''(x) > 0$, so f is concave up on the interval $\left(1 + \frac{2\sqrt{3}}{3}, \infty\right)$.

(c) Because the concavity of f changes at $1 + \frac{2\sqrt{3}}{3}$, the point

$$\left(1 + \frac{2\sqrt{3}}{3}, f\left(1 + \frac{2\sqrt{3}}{3}\right)\right) = \left(1 + \frac{2\sqrt{3}}{3}, \frac{\sqrt{9+6\sqrt{3}}}{2(3+\sqrt{3})}\right)$$

is a point of inflection of f .

75. Let $f(x) = x^2\sqrt{1-x^2}$. Note that the domain of f is the set $\{x \mid -1 \leq x \leq 1\}$.

(a) The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now,

$$f'(x) = x^2 \cdot \frac{1}{2}(1-x^2)^{-1/2}(-2x) + 2x\sqrt{1-x^2} = \frac{-x^3 + 2x - 2x^3}{\sqrt{1-x^2}} = \frac{x(2-3x^2)}{\sqrt{1-x^2}},$$

so ± 1 , 0 , and $\pm \frac{\sqrt{6}}{3}$ are critical numbers of f . To determine where $f'(x) > 0$ and $f'(x) < 0$,

use the numbers ± 1 , 0 , and $\pm \frac{\sqrt{6}}{3}$ to divide $[-1, 1]$ into four intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of x	Sign of $2-3x^2$	Sign of $\sqrt{1-x^2}$	Sign of $f'(x)$	Conclusion
$\left(-1, -\frac{\sqrt{6}}{3}\right)$	-	-	+	+	f is increasing
$\left(-\frac{\sqrt{6}}{3}, 0\right)$	-	+	+	-	f is decreasing
$\left(0, \frac{\sqrt{6}}{3}\right)$	+	+	+	+	f is increasing
$\left(\frac{\sqrt{6}}{3}, 1\right)$	+	-	+	-	f is decreasing

Therefore, f is increasing on the intervals $\left(-1, -\frac{\sqrt{6}}{3}\right)$ and $\left(0, \frac{\sqrt{6}}{3}\right)$ and decreasing on the intervals $\left(-\frac{\sqrt{6}}{3}, 0\right)$ and $\left(\frac{\sqrt{6}}{3}, 1\right)$. By the First Derivative Test, it follows that f has local maximum values at $\pm \frac{\sqrt{6}}{3}$ and a local minimum value at 0 . The

local maximum values are $f\left(\pm \frac{\sqrt{6}}{3}\right) = \frac{2\sqrt{3}}{9}$, and the local minimum value is $f(0) = 0$.

(b) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$\begin{aligned} f''(x) &= \frac{\sqrt{1-x^2}(2-9x^2) - (2x-3x^3) \cdot \frac{1}{2}(1-x^2)^{-1/2}(-2x)}{1-x^2} \\ &= \frac{(1-x^2)(2-9x^2) + x(2x-3x^3)}{(1-x^2)^{3/2}} = \frac{6x^4 - 9x^2 + 2}{(1-x^2)^{3/2}}, \end{aligned}$$

so $f''(x)$ does not exist at $x = \pm 1$ and is equal to zero when

$$x^2 = \frac{9 \pm \sqrt{81 - 4(6)(2)}}{12} = \frac{9 \pm \sqrt{33}}{12},$$

or when

$$x = \pm \sqrt{\frac{9 \pm \sqrt{33}}{12}} = \pm \frac{1}{6} \sqrt{27 \pm 3\sqrt{33}}.$$

Note that

$$\pm \frac{1}{6} \sqrt{27 + 3\sqrt{33}} \approx \pm 1.108$$

are not in the domain of f and can be excluded. To determine where $f''(x) > 0$ and $f''(x) < 0$, use the numbers $\pm \frac{1}{6} \sqrt{27 - 3\sqrt{33}}$ to divide $[-1, 1]$ into three intervals. The sign of $f''(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $6x^4 - 9x^2 + 2$	Sign of $(1 - x^2)^{3/2}$	Sign of $f''(x)$	Conclusion
$\left(-1, -\frac{1}{6}\sqrt{27 - 3\sqrt{33}}\right)$	−	+	−	f is concave down
$\left(-\frac{1}{6}\sqrt{27 - 3\sqrt{33}}, \frac{1}{6}\sqrt{27 - 3\sqrt{33}}\right)$	+	+	+	f is concave up
$\left(\frac{1}{6}\sqrt{27 - 3\sqrt{33}}, 1\right)$	−	+	−	f is concave down

Therefore, f is concave down on the intervals

$$\left(-1, -\frac{1}{6}\sqrt{27 - 3\sqrt{33}}\right) \quad \text{and} \quad \left(\frac{1}{6}\sqrt{27 - 3\sqrt{33}}, 1\right)$$

and concave up on the interval

$$\left(-\frac{1}{6}\sqrt{27 - 3\sqrt{33}}, \frac{1}{6}\sqrt{27 - 3\sqrt{33}}\right).$$

(c) Because the concavity of f changes at $\pm \frac{1}{6} \sqrt{27 - 3\sqrt{33}}$, the points

$$\left(\pm \frac{1}{6} \sqrt{27 - 3\sqrt{33}}, f\left(\pm \frac{1}{6} \sqrt{27 - 3\sqrt{33}}\right)\right) = \left(\pm \frac{1}{6} \sqrt{27 - 3\sqrt{33}}, \frac{9 - \sqrt{33}}{12} \sqrt{\frac{3 + \sqrt{33}}{12}}\right)$$

are points of inflection of f .

76. Let $f(x) = x\sqrt{1-x}$. Note that the domain of f is the set $\{x|x \leq 1\}$.

(a) The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now,

$$f'(x) = x \cdot \frac{1}{2}(1-x)^{-1/2}(-1) + \sqrt{1-x} = \frac{2-3x}{2\sqrt{1-x}},$$

so 1 and $\frac{2}{3}$ are critical numbers. For $x < \frac{2}{3}$, $f'(x) > 0$, so f is increasing on the interval $\left(-\infty, \frac{2}{3}\right)$; for $x > \frac{2}{3}$, $f'(x) < 0$, so f is decreasing on the interval $\left(\frac{2}{3}, 1\right)$. By the First Derivative Test, it

follows that f has a local maximum value at $\frac{2}{3}$. The local maximum value is $f\left(\frac{2}{3}\right) = \frac{2\sqrt{3}}{9}$.

- (b) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f''(x) = \frac{2\sqrt{1-x}(-3) - (2-3x) \cdot \frac{-1}{\sqrt{1-x}}}{4(1-x)} = \frac{3x-4}{4(1-x)^{3/2}}.$$

For $x < 1$, $f''(x) < 0$, so f is concave down on the interval $(-\infty, 1)$.

- (c) Because the concavity of f does not change, f has no points of inflection.

77. Let $f(x) = \sin^2 x$. Using the half-angle formula $\sin^2 x = \frac{1}{2}(1 - \cos(2x))$, we can see that f is a periodic function with period π .

- (a) The function f is differentiable everywhere, so critical numbers occur where $f'(x) = 0$. Now,

$$f'(x) = 2 \sin x \cos x = \sin(2x),$$

so $f'(x) = 0$ when $2x = k\pi$, where k is any integer. The critical numbers of f are therefore $\frac{k\pi}{2}$ for any integer k . To determine where $f'(x) > 0$ and $f'(x) < 0$, consider the intervals $\left(0, \frac{\pi}{2}\right)$ and $\left(\frac{\pi}{2}, \pi\right)$. The increasing/decreasing pattern demonstrated on these two intervals will repeat indefinitely in either direction. The results are shown in the table below.

Interval	Sign of $2 \sin x$	Sign of $\cos x$	Sign of $f'(x)$	Conclusion
$\left(0, \frac{\pi}{2}\right)$	+	+	+	f is increasing
$\left(\frac{\pi}{2}, \pi\right)$	+	-	-	f is decreasing

Therefore, f is increasing on intervals of the form $\left(k\pi, k\pi + \frac{\pi}{2}\right)$ and decreasing on intervals of the form $\left(k\pi + \frac{\pi}{2}, (k+1)\pi\right)$, where k is any integer. By the First Derivative Test, it follows that f has a local maximum value at $k\pi + \frac{\pi}{2}$ and a local minimum value at $k\pi$, for any integer k . The

local maximum values are $f\left(k\pi + \frac{\pi}{2}\right) = 1$, and the local minimum values are $f(k\pi) = 0$.

- (b) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f''(x) = 2 \cos(2x),$$

so $f''(x) = 0$ when $2x = \frac{(2k+1)\pi}{2}$ or $x = \frac{(2k+1)\pi}{4}$, where k is any integer. For $-\frac{\pi}{4} < x < \frac{\pi}{4}$, $f''(x) > 0$ while for $\frac{\pi}{4} < x < \frac{3\pi}{4}$, $f''(x) < 0$. Taking into account the period of the function f , it follows that f is concave up on intervals of the form $\left(k\pi - \frac{\pi}{4}, k\pi + \frac{\pi}{4}\right)$ and

concave down on intervals of the form $\left(k\pi + \frac{\pi}{4}, k\pi + \frac{3\pi}{4}\right)$ for any integer k .

- (c) Because the concavity of f changes at $\frac{(2k+1)\pi}{4}$ for any integer k , the points

$$\left(\frac{(2k+1)\pi}{4}, f\left(\frac{(2k+1)\pi}{4}\right)\right) = \left(\frac{(2k+1)\pi}{4}, \frac{1}{2}\right)$$

are points of inflection of f for any integer k .

78. Let $f(x) = \cos^2 x$. Using the half-angle formula $\cos^2 x = \frac{1}{2}(1 + \cos(2x))$, we can see that f is a periodic function with period π .

(a) The function f is differentiable everywhere, so critical numbers occur where $f'(x) = 0$. Now,

$$f'(x) = -2 \sin x \cos x = -\sin(2x),$$

so $f'(x) = 0$ when $2x = k\pi$, where k is any integer. The critical numbers of f are therefore $\frac{k\pi}{2}$ for any integer k . To determine where $f'(x) > 0$ and $f'(x) < 0$, consider the intervals $(0, \frac{\pi}{2})$ and $(\frac{\pi}{2}, \pi)$. The increasing/decreasing pattern demonstrated on these two intervals will repeat indefinitely in either direction in increments of the period π . The results are shown in the table below.

Interval	Sign of $-2 \sin x$	Sign of $\cos x$	Sign of $f'(x)$	Conclusion
$(0, \frac{\pi}{2})$	—	+	—	f is decreasing
$(\frac{\pi}{2}, \pi)$	—	—	+	f is increasing

Therefore, f is decreasing on intervals of the form $(k\pi, k\pi + \frac{\pi}{2})$ and increasing on intervals of the form $(k\pi + \frac{\pi}{2}, (k+1)\pi)$, where k is any integer. By the First Derivative Test, it follows that f has a local minimum value at $k\pi + \frac{\pi}{2}$ and a local maximum value at $k\pi$, for any integer k . The

local minimum values are $f(k\pi + \frac{\pi}{2}) = 0$, and the local maximum values are $f(k\pi) = 1$.

(b) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f''(x) = -2 \cos(2x),$$

so $f''(x) = 0$ when $2x = \frac{(2k+1)\pi}{2}$ or $x = \frac{(2k+1)\pi}{4}$, where k is any integer. For $-\frac{\pi}{4} < x < \frac{\pi}{4}$, $f''(x) < 0$ while for $\frac{\pi}{4} < x < \frac{3\pi}{4}$, $f''(x) > 0$. Taking into account the period of the function f , it follows that f is

concave down on intervals of the form $(k\pi - \frac{\pi}{4}, k\pi + \frac{\pi}{4})$ and concave up on intervals of the form $(k\pi + \frac{\pi}{4}, k\pi + \frac{3\pi}{4})$ for any integer k .

(c) Because the concavity of f changes at $\frac{(2k+1)\pi}{4}$ for any integer k , the points

$$\left(\frac{(2k+1)\pi}{4}, f\left(\frac{(2k+1)\pi}{4}\right) \right) = \left(\frac{(2k+1)\pi}{4}, \frac{1}{2} \right)$$

are points of inflection of f for any integer k .

79. Let $f(x) = x - 2 \sin x$, and consider the interval $[0, 2\pi]$.

(a) The function f is differentiable everywhere, so critical numbers occur where $f'(x) = 0$. Now,

$$f'(x) = 1 - 2 \cos x,$$

so $\frac{\pi}{3}$ and $\frac{5\pi}{3}$ are critical numbers. To determine where $f'(x) > 0$ and $f'(x) < 0$, use the numbers $\frac{\pi}{3}$ and $\frac{5\pi}{3}$ to divide $[0, 2\pi]$ into three intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $f'(x)$	Conclusion
$(0, \frac{\pi}{3})$	−	f is decreasing
$(\frac{\pi}{3}, \frac{5\pi}{3})$	+	f is increasing
$(\frac{5\pi}{3}, 2\pi)$	−	f is decreasing

Therefore, f is decreasing on the intervals $(0, \frac{\pi}{3})$ and $(\frac{5\pi}{3}, 2\pi)$ and increasing on the interval $(\frac{\pi}{3}, \frac{5\pi}{3})$. By the First Derivative Test, it follows that f has a local minimum value at $\frac{\pi}{3}$ and a local maximum value at $\frac{5\pi}{3}$. The local minimum value is $f\left(\frac{\pi}{3}\right) = \frac{\pi}{3} - \sqrt{3}$, and the

local maximum value is $f\left(\frac{5\pi}{3}\right) = \frac{5\pi}{3} + \sqrt{3}$.

- (b) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f''(x) = 2 \sin x,$$

so $f''(x) = 0$ when $x = 0, \pi$, and 2π . For $0 < x < \pi$, $f''(x) > 0$, so f is concave up on the interval $(0, \pi)$; for $\pi < x < 2\pi$, $f''(x) < 0$, so f is concave down on the interval $(\pi, 2\pi)$.

- (c) Because the concavity of f changes at π , the point $(\pi, f(\pi)) = (\pi, \pi)$ is a point of inflection of f .

80. Let $f(x) = 2 \cos^2 x - \sin^2 x$, and consider the interval $[0, 2\pi]$.

- (a) The function f is differentiable everywhere, so critical numbers occur where $f'(x) = 0$. Now,

$$f'(x) = -4 \cos x \sin x - 2 \sin x \cos x = -6 \sin x \cos x = -3 \sin(2x),$$

so $0, \frac{\pi}{2}, \pi, \frac{3\pi}{2}$, and 2π are critical numbers. To determine where $f'(x) > 0$ and $f'(x) < 0$, use the numbers $\frac{\pi}{2}, \pi$, and $\frac{3\pi}{2}$ to divide $[0, 2\pi]$ into four intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $-6 \sin x$	Sign of $\cos x$	Sign of $f'(x)$	Conclusion
$(0, \frac{\pi}{2})$	−	+	−	f is decreasing
$(\frac{\pi}{2}, \pi)$	−	−	+	f is increasing
$(\pi, \frac{3\pi}{2})$	+	−	−	f is decreasing
$(\frac{3\pi}{2}, 2\pi)$	+	+	+	f is increasing

Therefore, f is decreasing on the intervals $(0, \frac{\pi}{2})$ and $(\pi, \frac{3\pi}{2})$ and increasing on the intervals $(\frac{\pi}{2}, \pi)$ and $(\frac{3\pi}{2}, 2\pi)$. By the First Derivative Test, it follows that f has local minimum values at

$\frac{\pi}{2}$ and $\frac{3\pi}{2}$ and a local maximum value at π . The local minimum values are $f\left(\frac{\pi}{2}\right) = f\left(\frac{3\pi}{2}\right) = -1$, and the local maximum value is $f(\pi) = 2$.

- (b) The function f is concave up where $f''(x) > 0$ and concave down where $f''(x) < 0$. Now,

$$f''(x) = -6 \cos(2x),$$

so $f''(x) = 0$ when $x = \frac{\pi}{4}, \frac{3\pi}{4}, \frac{5\pi}{4},$ and $\frac{7\pi}{4}$. To determine where $f''(x) > 0$ and $f''(x) < 0$, use the numbers $\frac{\pi}{4}, \frac{3\pi}{4}, \frac{5\pi}{4}$ and $\frac{7\pi}{4}$ to divide $[0, 2\pi]$ into five intervals. The sign of $f''(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $f''(x)$	Conclusion
$\left(0, \frac{\pi}{4}\right)$	—	f is concave down
$\left(\frac{\pi}{4}, \frac{3\pi}{4}\right)$	+	f is concave up
$\left(\frac{3\pi}{4}, \frac{5\pi}{4}\right)$	—	f is concave down
$\left(\frac{5\pi}{4}, \frac{7\pi}{4}\right)$	+	f is concave up
$\left(\frac{7\pi}{4}, 2\pi\right)$	—	f is concave down

Therefore, f is concave down on the intervals $\left(0, \frac{\pi}{4}\right), \left(\frac{3\pi}{4}, \frac{5\pi}{4}\right),$ and $\left(\frac{7\pi}{4}, 2\pi\right)$ and concave up on the intervals $\left(\frac{\pi}{4}, \frac{3\pi}{4}\right)$ and $\left(\frac{5\pi}{4}, \frac{7\pi}{4}\right)$.

- (c) Because the concavity of f changes at $\frac{\pi}{4}, \frac{3\pi}{4}, \frac{5\pi}{4},$ and $\frac{7\pi}{4}$, the points

$$\left(\frac{\pi}{4}, f\left(\frac{\pi}{4}\right)\right) = \left(\frac{\pi}{4}, \frac{1}{2}\right), \quad \left(\frac{3\pi}{4}, f\left(\frac{3\pi}{4}\right)\right) = \left(\frac{3\pi}{4}, \frac{1}{2}\right),$$

$$\left(\frac{5\pi}{4}, f\left(\frac{5\pi}{4}\right)\right) = \left(\frac{5\pi}{4}, \frac{1}{2}\right), \quad \text{and} \quad \left(\frac{7\pi}{4}, f\left(\frac{7\pi}{4}\right)\right) = \left(\frac{7\pi}{4}, \frac{1}{2}\right)$$

are points of inflection of f .

81. Let $f(x) = -2x^3 + 15x^2 - 36x + 7$. The polynomial function f is differentiable everywhere, so critical numbers occur where $f'(x) = 0$. Now,

$$f'(x) = -6x^2 + 30x - 36 = -6(x^2 - 5x + 6) = -6(x - 3)(x - 2),$$

so 2 and 3 are the critical numbers of f .

- (a) To determine where $f'(x) > 0$ and $f'(x) < 0$, use the numbers 2 and 3 to divide the number line into three intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $-6(x - 3)$	Sign of $x - 2$	Sign of $f'(x)$	Conclusion
$(-\infty, 2)$	+	—	—	f is decreasing
$(2, 3)$	+	+	+	f is increasing
$(3, \infty)$	—	+	—	f is decreasing

Therefore, f is decreasing on the intervals $(-\infty, 2)$ and $(3, \infty)$ and increasing on the interval $(2, 3)$. By the First Derivative Test, it follows that f has a local minimum value at 2 and a local maximum value at 3. The

$$\text{local minimum value is } f(2) = -21, \text{ and the local maximum value is } f(3) = -20.$$

- (b) The second derivative of
- f
- is

$$f''(x) = -12x + 30.$$

Evaluating the second derivative at the critical numbers yields

$$f''(2) = 6 > 0 \quad \text{and} \quad f''(3) = -6 < 0.$$

By the Second Derivative Test, it follows that f has a local minimum value at 2 and a local maximum value at 3.

- (c) Answers will vary, but here is one possible response. Neither test is particularly difficult to use. The First Derivative Test requires the calculation of only one derivative, but the Second Derivative Test requires fewer steps.

82. Let $f(x) = x^3 + 10x^2 + 25x - 25$. The polynomial function f is differentiable everywhere, so critical numbers occur where $f'(x) = 0$. Now,

$$f'(x) = 3x^2 + 20x + 25 = (3x + 5)(x + 5),$$

so -5 and $-\frac{5}{3}$ are the critical numbers of f .

- (a) To determine where $f'(x) > 0$ and $f'(x) < 0$, use the numbers -5 and $-\frac{5}{3}$ to divide the number line into three intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $3x + 5$	Sign of $x + 5$	Sign of $f'(x)$	Conclusion
$(-\infty, -5)$	—	—	+	f is increasing
$(-5, -\frac{5}{3})$	—	+	—	f is decreasing
$(-\frac{5}{3}, \infty)$	+	+	+	f is increasing

Therefore, f is increasing on the intervals $(-\infty, -5)$ and $(-\frac{5}{3}, \infty)$ and decreasing on the interval $(-5, -\frac{5}{3})$. By the First Derivative Test, it follows that f has a local maximum value at -5 and a local minimum value at $-\frac{5}{3}$. The

local maximum value is $f(-5) = -25$, and the local minimum value is $f\left(-\frac{5}{3}\right) = -\frac{1175}{27}$.

- (b) The second derivative of f is

$$f''(x) = 6x + 20.$$

Evaluating the second derivative at the critical numbers yields

$$f''(-5) = -10 < 0 \quad \text{and} \quad f''\left(-\frac{5}{3}\right) = 10 > 0.$$

By the Second Derivative Test, it follows that f has a local maximum value at -5 and a local minimum value at $-\frac{5}{3}$.

- (c) Answers will vary, but here is one possible response. Neither test is particularly difficult to use. The First Derivative Test requires the calculation of only one derivative, but the Second Derivative Test requires fewer steps.

83. Let $f(x) = (x - 3)^2 e^x$. The function f is differentiable everywhere, so critical numbers occur where $f'(x) = 0$. Now,

$$f'(x) = (x - 3)^2 e^x + 2(x - 3)e^x = (x^2 - 4x + 3)e^x = (x - 3)(x - 1)e^x,$$

so 1 and 3 are the critical numbers of f

- (a) To determine where $f'(x) > 0$ and $f'(x) < 0$, use the numbers 1 and 3 to divide the number line into three intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $x - 3$	Sign of $(x - 1)e^x$	Sign of $f'(x)$	Conclusion
$(-\infty, 1)$	—	—	+	f is increasing
$(1, 3)$	—	+	—	f is decreasing
$(3, \infty)$	+	+	+	f is increasing

Therefore, f is increasing on the intervals $(-\infty, 1)$ and $(3, \infty)$ and decreasing on the interval $(1, 3)$. By the First Derivative Test, it follows that f has a local maximum value at 1 and a local minimum value at 3. The

local maximum value is $f(1) = 4e$, and the local minimum value is $f(3) = 0$.

- (b) The second derivative of f is

$$f''(x) = (x^2 - 4x + 3)e^x + (2x - 4)e^x = (x^2 - 2x - 1)e^x.$$

Evaluating the second derivative at the critical numbers yields

$$f''(1) = -2e < 0 \quad \text{and} \quad f''(3) = 2e > 0.$$

By the Second Derivative Test, it follows that f has a local maximum value at 1 and a local minimum value at 3.

- (c) Answers will vary, but here is one possible response. Neither test is particularly difficult to use. The First Derivative Test requires the calculation of only one derivative, but the Second Derivative Test requires fewer steps.
84. Let $f(x) = (x + 1)^2 e^{-x}$. The function f is differentiable everywhere, so critical numbers occur where $f'(x) = 0$. Now,

$$f'(x) = -(x + 1)^2 e^{-x} + 2(x + 1)e^{-x} = (-x^2 + 1)e^{-x} = (x + 1)(1 - x)e^{-x},$$

so -1 and 1 are the critical numbers of f .

- (a) To determine where $f'(x) > 0$ and $f'(x) < 0$, use the numbers -1 and 1 to divide the number line into three intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $x + 1$	Sign of $(1 - x)e^{-x}$	Sign of $f'(x)$	Conclusion
$(-\infty, -1)$	—	+	—	f is decreasing
$(-1, 1)$	+	+	+	f is increasing
$(1, \infty)$	+	—	—	f is decreasing

Therefore, f is decreasing on the intervals $(-\infty, -1)$ and $(1, \infty)$ and increasing on the interval $(-1, 1)$. By the First Derivative Test, it follows that f has a local minimum value at -1 and a local maximum value at 1 . The

$$\boxed{\text{local minimum value is } f(-1) = 0, \text{ and the local maximum value is } f(1) = 4e^{-1}}.$$

(b) The second derivative of f is

$$f''(x) = -(-x^2 + 1)e^{-x} - 2xe^{-x} = (x^2 - 2x - 1)e^{-x}.$$

Evaluating the second derivative at the critical numbers yields

$$f''(-1) = 2e > 0 \quad \text{and} \quad f''(1) = -2e^{-1} < 0.$$

By the Second Derivative Test, it follows that f has a $\boxed{\text{local minimum value at } -1}$ and a $\boxed{\text{local maximum value at } 1}$.

(c) Answers will vary, but here is one possible response. Neither test is particularly difficult to use. The First Derivative Test requires the calculation of only one derivative, but the Second Derivative Test requires fewer steps.

Applications and Extensions

85. Answers will vary. The figure below displays the graph of a function f with the properties: f is concave up on $(-\infty, \infty)$, increasing on $(-\infty, 0)$, decreasing on $(0, \infty)$, and $f(0) = 1$.

86. Answers will vary. The figure below displays the graph of a function f with the properties: f is concave up on $(-\infty, 0)$, concave down on $(0, \infty)$, decreasing on $(-\infty, 0)$, increasing on $(0, \infty)$, and $f(0) = 1$.

87. Answers will vary. The figure below displays the graph of a function f with the properties: f is concave down on $(-\infty, 1)$, concave up on $(1, \infty)$, decreasing on $(-\infty, 0)$, increasing on $(0, \infty)$, and $f(0) = 1$ and $f(1) = 2$.

88. Answers will vary. The figure below displays the graph of a function f with the properties: f is concave down on $(-\infty, 0)$, concave up on $(0, \infty)$, increasing on $(-\infty, \infty)$, and $f(0) = 1$ and $f(1) = 2$.

89. Answers will vary. The figure below displays the graph of a function f with the properties: $f'(x) > 0$ if $x < 0$, $f'(x) < 0$ if $x > 0$, $f''(x) > 0$ if $x < 0$, $f''(x) < 0$ if $x > 0$, and $f(0) = 1$.

90. Answers will vary. The figure below displays the graph of a function f with the properties: $f'(x) > 0$ if $x < 0$, $f'(x) < 0$ if $x > 0$, $f''(x) > 0$ if $x < 0$, $f''(x) < 0$ if $x > 0$, and $f(0) = 1$.

91. Answers will vary. The figure below displays the graph of a function f with the properties: $f''(0) = 0$, $f'(0) = 0$, $f''(x) > 0$ if $x < 0$, $f''(x) > 0$ if $x > 0$, and $f(0) = 1$.

92. Answers will vary. The figure below displays the graph of a function f with the properties: $f''(0) = 0$, $f'(x) > 0$ if $x \neq 0$, $f''(x) < 0$ if $x < 0$, $f''(x) > 0$ if $x > 0$, and $f(0) = 1$.

93. Answers will vary. The figure below displays the graph of a function f with the properties: $f'(0) = 0$, $f'(x) < 0$ if $x \neq 0$, $f''(x) > 0$ if $x < 0$, $f''(x) < 0$ if $x > 0$, and $f(0) = 1$.

94. Answers will vary. The figure below displays the graph of a function f with the properties: $f''(0) = 0$, $f'(0) = \frac{1}{2}$, $f''(x) > 0$ if $x < 0$, $f''(x) < 0$ if $x > 0$, and $f(0) = 1$.

95. Answers will vary. The figure below displays the graph of a function f with the properties: $f'(0)$ does not exist, $f''(x) > 0$ if $x < 0$, $f''(x) > 0$ if $x > 0$, and $f(0) = 1$.

96. Answers will vary. The figure below displays the graph of a function f with the properties: $f'(0)$ does not exist, $f''(x) < 0$ if $x < 0$, $f''(x) > 0$ if $x > 0$, and $f(0) = 1$.

97. Let $f(x) = e^{-(x-2)^2}$.

(a) Using the command

`Reduce [ D [ Exp[-(x-2)^2], {x,2} ] > 0, x ]`

in *Mathematica* yields the solution

$$x < 2 - \frac{\sqrt{2}}{2} \quad \text{or} \quad x > 2 + \frac{\sqrt{2}}{2}$$

to the inequality $f''(x) > 0$; the command

`Reduce [ D [ Exp[-(x-2)^2], {x,2} ] < 0, x ]`

yields the solution

$$2 - \frac{\sqrt{2}}{2} < x < 2 + \frac{\sqrt{2}}{2}$$

to the inequality $f''(x) < 0$. Therefore, f is

concave up on the intervals $\left(-\infty, 2 - \frac{\sqrt{2}}{2}\right)$ and $\left(2 + \frac{\sqrt{2}}{2}, \infty\right)$

and $\text{concave down on the interval } \left(2 - \frac{\sqrt{2}}{2}, 2 + \frac{\sqrt{2}}{2}\right)$.

- (b) Because the concavity of f changes at $2 \pm \frac{\sqrt{2}}{2}$, the points

$$\left(2 - \frac{\sqrt{2}}{2}, f\left(2 - \frac{\sqrt{2}}{2}\right)\right) = \left(2 - \frac{\sqrt{2}}{2}, \frac{1}{\sqrt{e}}\right)$$

and

$$\left(2 + \frac{\sqrt{2}}{2}, f\left(2 + \frac{\sqrt{2}}{2}\right)\right) = \left(2 + \frac{\sqrt{2}}{2}, \frac{1}{\sqrt{e}}\right)$$

are points of inflection of f .

- (c) The figure below displays the graph of f with the points of inflection marked with black squares. At the point on the left, the concavity changes from up to down, while at the point on the right, the concavity changes from down to up.

98. Let $f(x) = x^2\sqrt{5-x}$.

- (a) Using the command

`Reduce [ D [  $x^2 \text{ Sqrt}[5-x]$ , {x,2} ] > 0, x ]`

in *Mathematica* yields the solution

$$x < 4 - \frac{2\sqrt{6}}{3}$$

to the inequality $f''(x) > 0$; the command

`Reduce [ D [  $x^2 \text{ Sqrt}[5-x]$ , {x,2} ] < 0, x ]`

yields the solution

$$4 - \frac{2\sqrt{6}}{3} < x < 5$$

to the inequality $f''(x) < 0$. Therefore, f is $\text{concave up on the interval } \left(-\infty, 4 - \frac{2\sqrt{6}}{3}\right)$ and

$\text{concave down on the interval } \left(4 - \frac{2\sqrt{6}}{3}, 5\right)$.

- (b) Because the concavity of f changes at $4 - \frac{2\sqrt{6}}{3}$, the point

$$\left(4 - \frac{2\sqrt{6}}{3}, f\left(4 - \frac{2\sqrt{6}}{3}\right)\right) = \left(4 - \frac{2\sqrt{6}}{3}, \frac{1}{27}(12 - 2\sqrt{6})^2 \sqrt{9 + 6\sqrt{6}}\right)$$

is a point of inflection of f .

- (c) The figure below displays the graph of f with the point of inflection marked with a black square. At the point inflection, the concavity changes from up to down.

99. Let $f(x) = \frac{2-x}{2x^2-2x+1}$.

- (a) Using the command

$$\text{N [Reduce [D [(2-x)/(2x^2 - 2x + 1), \{x,2\}] > 0, x]]}$$

in *Mathematica* yields the approximate solution

$$x < 0.134792 \quad \text{or} \quad 0.7211 < x < 5.14411$$

to the inequality $f''(x) > 0$; the command

$$\text{N [Reduce [D [(2-x)/(2x^2 - 2x + 1), \{x,2\}] < 0, x]]}$$

yields the approximate solution

$$0.134792 < x < 0.7211 \quad \text{or} \quad x > 5.14411$$

to the inequality $f''(x) < 0$. Therefore, f is

$$\text{concave up on the intervals } (-\infty, 0.134792) \text{ and } (0.7211, 5.14411)$$

and $\text{concave down on the intervals } (0.134792, 0.7211) \text{ and } (5.14411, \infty)$.

- (b) Because the concavity of f changes at approximately 0.134792, 0.7211, and 5.14411, the points

$$(0.134792, f(0.134792)) = (0.134792, 2.43260),$$

$$(0.7211, f(0.7211)) = (0.7211, 2.13945), \text{ and}$$

$$(5.14411, f(5.14411)) = (5.14411, -0.07205)$$

are approximately the points of inflection of f .

- (c) The figure below displays the graph of f with the points of inflection marked with black squares. From left to right, the concavity changes from up to down, down to up, and up to down at the inflection points.

100. Let $f(x) = \frac{3x}{x^2 + 3x + 5}$.

- (a) Using the command

$$\text{N [Reduce [D [(3x)/(x^2 + 3x + 5), \{x, 2\}] > 0, x]]}$$

in *Mathematica* yields the approximate solution

$$-3.21463 < x < -1.0852 \quad \text{or} \quad x > 4.29983$$

to the inequality $f''(x) > 0$; the command

$$\text{N [Reduce [D [(3x)/(x^2 + 3x + 5), \{x, 2\}] < 0, x]]}$$

yields the approximate solution

$$x < -3.21463 \quad \text{or} \quad -1.0852 < x < 4.29983$$

to the inequality $f''(x) < 0$. Therefore, f is

$$\boxed{\text{concave up on the intervals } (-3.21463, -1.0852) \text{ and } (4.29983, \infty)}$$

and $\boxed{\text{concave down on the intervals } (-\infty, -3.21463) \text{ and } (-1.0852, 4.29983)}$.

- (b) Because the concavity of f changes at approximately -3.21463 , -1.0852 , and 4.29983 , the points

$$\begin{aligned} (-3.21463, f(-3.21463)) &= \boxed{(-3.21463, -1.69490)}, \\ (-1.0852, f(-1.0852)) &= \boxed{(-1.0852, -1.11415)}, \text{ and} \\ (4.29983, f(4.29883)) &= \boxed{(4.29883, 0.35450)} \end{aligned}$$

are approximately the points of inflection of f .

- (c) The figure below displays the graph of f with the points of inflection marked with black squares. From left to right, the concavity changes from down to up, up to down, and down to up at the inflection points.

101. Let $f(x) = \sqrt[3]{x}$. The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now,

$$f'(x) = \frac{1}{3}x^{-2/3} = \frac{1}{3\sqrt[3]{x^2}},$$

so $f'(x)$ does not exist when $x = 0$ and is never equal to 0. Therefore, 0 is the only critical number of f . Additionally, $f'(x) > 0$ for $x \neq 0$, so f is increasing on the intervals $(-\infty, 0)$ and $(0, \infty)$. By the First Derivative Test, it follows that f has neither a local maximum nor a local minimum at 0; therefore, f has no local extrema.

102. Let $f(x) = \sqrt[3]{x^2}$. The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now,

$$f'(x) = \frac{2}{3}x^{-1/3} = \frac{2}{3\sqrt[3]{x}},$$

so $f'(x)$ does not exist when $x = 0$ and is never equal to 0. Therefore, 0 is the only critical number of f . Additionally, $f'(x) < 0$ for $x < 0$ and $f'(x) > 0$ for $x > 0$, so f is decreasing on the interval $(-\infty, 0)$ and increasing on the interval $(0, \infty)$. By the First Derivative Test, it follows that f has a local minimum at 0.

103. Let $f(x) = ax^3 + bx^2$. For the point $(1, 6)$ to be on the graph of f , $f(1)$ must be equal to 6. As $f(1) = a + b$, the numbers a and b must satisfy the equation $a + b = 6$. Because the polynomial function f is twice differentiable everywhere, if f is to have an inflection point at the point $(1, 6)$, $f''(1)$ must be equal to 0. Now,

$$f'(x) = 3ax^2 + 2bx \quad \text{and} \quad f''(x) = 6ax + 2b,$$

so $f''(1) = 6a + 2b$ and another equation that a and b must satisfy is $6a + 2b = 0$. Solving $a + b = 6$ and $6a + 2b = 0$ yields $\boxed{a = -3 \text{ and } b = 9}$.

104. Let $f(x) = ax^3 + bx^2 + cx + d$. The condition $f(0) = 4$ requires that $d = 4$. For the point $(1, -2)$ to be on the graph of f , $f(1)$ must be equal to -2 . As $f(1) = a + b + c + d$, the numbers a , b , c , and d must satisfy the equation $a + b + c + d = -2$. Because the polynomial function f is twice differentiable everywhere, for 0 to be a critical number of f , $f'(0)$ must be equal to 0. Additionally, for f to have an inflection point at $(1, -2)$, $f''(1)$ must be equal to 0. Now,

$$f'(x) = 3ax^2 + 2bx + c \quad \text{and} \quad f''(x) = 6ax + 2b,$$

so $f'(0) = c$ and $f''(1) = 6a + 2b$. It follows that a , b , c , and d must also satisfy the equations $c = 0$ and $6a + 2b = 0$. Solving $d = 4$, $a + b + c + d = -2$, $c = 0$, and $6a + 2b = 0$ yields $\boxed{a = 3, b = -9, c = 0, \text{ and } d = 4}$.

105. Let $N(t) = \frac{10,000}{1 + 9999e^{-t}}$.

- (a) The rate of change of the infection is

$$N'(t) = \frac{(1 + 9999e^{-t}) \cdot 0 - 10,000 \cdot -9999e^{-t}}{(1 + 9999e^{-t})^2} = \frac{99,990,000e^{-t}}{(1 + 9999e^{-t})^2}.$$

- (b) $N'(t)$ is increasing when $N''(t) > 0$ and decreasing when $N''(t) < 0$. Now,

$$\begin{aligned} N''(t) &= \frac{(1 + 9999e^{-t})^2 \cdot -99,990,000e^{-t} - 99,990,000e^{-t} \cdot 2(1 + 9999e^{-t})(-9999e^{-t})}{(1 + 9999e^{-t})^4} \\ &= \frac{99,990,000e^{-t}(19998e^{-t} - 1 - 9999e^{-t})}{(1 + 9999e^{-t})^3} = \frac{99,990,000e^{-t}(9999e^{-t} - 1)}{(1 + 9999e^{-t})^3}, \end{aligned}$$

so $N''(t) = 0$ when

$$9999e^{-t} - 1 = 0 \quad \text{or} \quad t = \ln 9999.$$

For $0 < t < \ln 9999$, $N''(t) > 0$, so $N'(t)$ is increasing on the interval $(0, \ln 9999)$.

For $t > \ln 9999$, $N''(t) < 0$, so $N'(t)$ is decreasing on the interval $(\ln 9999, \infty)$.

- (c) Based on the results of part (b) and the First Derivative Test, the rate of change of the infection is a maximum when $t = \ln 9999$.
- (d) Based on the results of part (b), N is concave up on the interval $(0, \ln 9999)$ and concave down on the interval $(\ln 9999, \infty)$. Therefore, the concavity of N changes at $\ln 9999$, and the point

$$(\ln 9999, N(\ln 9999)) = (\ln 9999, 5000)$$

is an inflection point of N .

- (e) Comparing the results of parts (c) and (d), we see that the point of inflection of N is the point at which $N'(t)$ is maximum.

106. Let $P(t) = \frac{300}{1 + 50e^{-0.2t}}$.

- (a) The annual profit is increasing when $P'(t) > 0$ and decreasing when $P'(t) < 0$. Now,

$$P'(t) = \frac{(1 + 50e^{-0.2t}) \cdot 0 - 300 \cdot -10e^{-0.2t}}{(1 + 50e^{-0.2t})^2} = \frac{3000e^{-0.2t}}{(1 + 50e^{-0.2t})^2}.$$

Note that $P'(t) > 0$ for all t , so annual profit is increasing on the interval $(0, \infty)$ and is never decreasing.

- (b) From part (a), the rate of change in profit is

$$P'(t) = \frac{3000e^{-0.2t}}{(1 + 50e^{-0.2t})^2}.$$

- (c) The rate of change in profit $P'(t)$ is increasing when $P''(t) > 0$ and decreasing when $P''(t) < 0$. Now,

$$\begin{aligned} P''(t) &= \frac{(1 + 50e^{-0.2t})^2 \cdot -600e^{-0.2t} - 3000e^{-0.2t} \cdot 2(1 + 50e^{-0.2t})(-10e^{-0.2t})}{(1 + 50e^{-0.2t})^4} \\ &= \frac{600e^{-0.2t}(100e^{-0.2t} - 1 - 50e^{-0.2t})}{(1 + 50e^{-0.2t})^3} = \frac{600e^{-0.2t}(50e^{-0.2t} - 1)}{(1 + 50e^{-0.2t})^3}, \end{aligned}$$

so $P''(t) = 0$ when

$$50e^{-0.2t} - 1 = 0 \quad \text{or} \quad t = 5 \ln 50.$$

For $0 < t < 5 \ln 50$, $P''(t) > 0$, so $P'(t)$ is increasing on the interval $(0, 5 \ln 50)$. For $t > 5 \ln 50$, $P''(t) < 0$, so $P'(t)$ is decreasing on the interval $(5 \ln 50, \infty)$.

- (d) Based on the results of part (c) and the First Derivative Test, the rate of change in profit is a maximum when $t = 5 \ln 50$.
- (e) Based on the results of part (c), P is concave up on the interval $(0, 5 \ln 50)$ and concave down on the interval $(5 \ln 50, \infty)$. Therefore, the concavity of P changes at $5 \ln 50$, and the point

$$(5 \ln 50, P(5 \ln 50)) = (5 \ln 50, 150)$$

is an inflection point of P .

- (f) Comparing the results of parts (d) and (e), we see that the point of inflection of P is the point at which $P'(t)$ is maximum.

107. (a) The figure below displays a scatterplot of the population data.

- (b) Using the **Logistic** regression function on a TI-84 Plus calculator, the logistic function that best fits the given data is

$$P(t) = \frac{762,176,717.8}{1 + 8.743e^{-0.0162t}}.$$

- (c) The rate of change in population is

$$P'(t) = \frac{(1 + 8.743e^{-0.0162t}) \cdot 0 - 762,176,717.8 \cdot -0.1416366e^{-0.0162t}}{(1 + 8.743e^{-0.0162t})^2} = \frac{107,952,118.9e^{-0.0162t}}{(1 + 8.743e^{-0.0162t})^2}.$$

- (d) $P'(t)$ is increasing when $P''(t) > 0$ and decreasing when $P''(t) < 0$. Now,

$$\begin{aligned} P''(t) &= \frac{(1 + 8.743e^{-0.0162t})^2 \cdot -1,748,824.326e^{-0.0162t}}{(1 + 8.743e^{-0.0162t})^4} - \frac{107,952,118.9e^{-0.0162t} \cdot 2(1 + 8.743e^{-0.0162t})(-0.1416366e^{-0.0162t})}{(1 + 8.743e^{-0.0162t})^4} \\ &= \frac{1,748,824.326e^{-0.0162t}(17.486e^{-0.0162t} - 1 - 8.743e^{-0.0162t})}{(1 + 8.743e^{-0.0162t})^3} \\ &= \frac{1,748,824.326e^{-0.0162t}(8.743e^{-0.0162t} - 1)}{(1 + 8.743e^{-0.0162t})^3}, \end{aligned}$$

so $P''(t) = 0$ when

$$8.743e^{-0.0162t} - 1 = 0 \quad \text{or} \quad t = \frac{1}{0.0162} \ln 8.743 \approx 133.843.$$

For $0 < t < 133.843$, $P''(t) > 0$, so $P'(t)$ is increasing on the interval $(0, 133.843)$. For $t > 133.843$, $P''(t) < 0$, so $P'(t)$ is decreasing on the interval $(133.843, \infty)$.

- (e) Based on the results of part (d) and the First Derivative Test, the rate of change in population is a maximum when $t \approx 133.843$.
- (f) Based on the results of part (d), P is concave up on the interval $(0, 133.843)$ and concave down on the interval $(133.843, \infty)$. Therefore, the concavity of P changes at 133.843, and the point

$$(133.843, P(133.843)) \approx (133.843, 381088358.9)$$

is an inflection point of P .

- (g) Comparing the results of parts (e) and (f), we see that the point of inflection of P is the point at which $P'(t)$ is maximum.

108. (a) The figure below displays a scatterplot of the yeast biomass data.

- (b) Using the **Logistic** regression function on a TI-84 Plus calculator, the logistic function that best fits the given data is

$$y = \frac{663.0}{1 + 71.6e^{-0.5470t}}.$$

- (c) The rate of change in biomass is

$$y'(t) = \frac{(1 + 71.6e^{-0.5470t}) \cdot 0 - 663.0 \cdot -39.1652e^{-0.5470t}}{(1 + 71.6e^{-0.5470t})^2} = \frac{25,966.5276e^{-0.5470t}}{(1 + 71.6e^{-0.5470t})^2}.$$

- (d) $y'(t)$ is increasing when $y''(t) > 0$ and decreasing when $y''(t) < 0$. Now,

$$\begin{aligned} y''(t) &= \frac{(1 + 71.6e^{-0.5470t})^2 \cdot -14,203.6906e^{-0.5470t}}{(1 + 71.6e^{-0.5470t})^4} - \frac{25,966.5276e^{-0.5470t} \cdot 2(1 + 71.6e^{-0.5470t})(-39.1652e^{-0.5470t})}{(1 + 71.6e^{-0.5470t})^4} \\ &= \frac{14,203.6906e^{-0.5470t}(143.2e^{-0.5470t} - 1 - 71.6e^{-0.5470t})}{(1 + 71.6e^{-0.5470t})^3} \\ &= \frac{14,203.6906e^{-0.5470t}(71.6e^{-0.5470t} - 1)}{(1 + 71.6e^{-0.5470t})^3}, \end{aligned}$$

so $y''(t) = 0$ when

$$71.6e^{-0.5470t} - 1 = 0 \quad \text{or} \quad t = \frac{1}{0.5470} \ln 71.6 \approx 7.808.$$

For $0 < t < 7.808$, $y''(t) > 0$, so $y'(t)$ is increasing on the interval $(0, 7.808)$. For $t > 7.808$, $y''(t) < 0$, so $y'(t)$ is decreasing on the interval $(7.808, \infty)$.

- (e) Based on the results of part (d) and the First Derivative Test, the rate of change in biomass is a maximum when $t \approx 7.808$.
- (f) Based on the results of part (d), y is concave up on the interval $(0, 7.808)$ and concave down on the interval $(7.808, \infty)$. Therefore, the concavity of y changes at 7.808, and the point

$$(7.808, y(7.808)) \approx (7.808, 331.5)$$

is an inflection point of y .

- (g) Comparing the results of parts (e) and (f), we see that the point of inflection of y is the point at which $y'(t)$ is maximum.

109. Let $B(t) = -12.8t^3 + 163.4t^2 - 614.0t + 390.6$.

- (a) The polynomial function B is differentiable everywhere, so the critical numbers of B occur where $B'(t) = 0$. Now,

$$B'(t) = -38.4t^2 + 326.8t - 614.0,$$

so the critical numbers of B are

$$t = \frac{-326.8 \pm \sqrt{326.8^2 - 4(-38.4)(-614.0)}}{-76.8} = \frac{-326.8 \pm \sqrt{12487.84}}{-76.8} \approx 2.80, 5.71.$$

Evaluating $B''(t) = -76.8t + 326.8$ at the critical numbers yields

$$B''(2.80) = 111.76 > 0 \quad \text{and} \quad B''(5.71) = -111.728 < 0,$$

so B has a local minimum value at 2.80 and a local maximum value at 5.71. The

$$\text{local minimum value is } B(2.80) \approx -328.53 \text{ billion dollars},$$

and the $\text{local maximum value is } B(5.71) \approx -170.80 \text{ billion dollars}.$

- (b) Because both local extreme values are negative, both represent a $\text{budget deficit}.$
- (c) From part (a), $B''(t) = -76.8t + 326.8$, so $B''(t) = 0$ when $t \approx 4.26$. For $0 < t < 4.26$, $B''(t) > 0$, so B is $\text{concave up on the interval } (0, 4.26);$ for $4.26 < t < 9$, $B''(t) < 0$, so B is $\text{concave down on the interval } (4.26, 9).$ Because the concavity of B changes at 4.26, the point $(4.26, B(4.26)) \approx (4.26, -249.27)$ is a point of inflection of B .
- (d) Because $B''(t) > 0$ for $t < 4.26$, to the left of the point of inflection, the rate of change of the budget is increasing at an increasing rate; because $B''(t) < 0$ for $t > 4.26$, to the right of the point of inflection, the rate of change of the budget is increasing at a decreasing rate.
- (e) The figure below displays the graph of B . Given that B predicts a 3.6 trillion dollar budget deficit in 2011, which would indicate that the government took in nothing in 2011, B does not seem to be an accurate predictor for the budget for the years 2010 and beyond.

110. Let $f(x) = ax^3 + bx^2 + cx + d$, where $a \neq 0$. Because local extrema can only occur at critical numbers and the polynomial function f is differentiable everywhere, local extrema of f can only occur where $f'(x) = 0$. Now,

$$f'(x) = 3ax^2 + 2bx + c,$$

so $f'(x) = 0$ when

$$x = \frac{-2b \pm \sqrt{(2b)^2 - 4(3a)(c)}}{6a} = \frac{-b \pm \sqrt{b^2 - 3ac}}{3a}.$$

Therefore, the number of critical numbers, and therefore the number of potential local extrema, depends on the sign of the discriminant $b^2 - 3ac$.

111. Let $f(x) = ax^3 + bx^2 + cx + d$, where $a \neq 0$. In order for the graph of f to contain the points $(0, 5)$ and $(4, 33)$, $f(0)$ must be equal to 5 and $f(4)$ must be equal to 33. These conditions yield the equations $d = 5$ and $64a + 16b + 4c + d = 33$. The polynomial function f is differentiable everywhere, so for f to have a local minimum at 0 and a local maximum at 4, both $f'(0)$ and $f'(4)$ must be equal to 0. Now,

$$f'(x) = 3ax^2 + 2bx + c,$$

so the derivative conditions yield the equations $c = 0$ and $48a + 8b + c = 0$. The solution of the equations

$$d = 5, 64a + 16b + 4c + d = 33, c = 0, \text{ and } 48a + 8b + c = 0 \text{ is } \boxed{a = -\frac{7}{8}, b = \frac{21}{4}, c = 0, \text{ and } d = 5}.$$

112. Let $f(x) = \frac{2}{x} + \frac{8}{1-x}$. Then

$$f'(x) = -\frac{2}{x^2} + \frac{8}{(1-x)^2},$$

so $f'(x) = 0$ when

$$\begin{aligned} \frac{2}{x^2} &= \frac{8}{(1-x)^2} \\ (1-x)^2 &= 4x^2 \\ 1-2x+x^2 &= 4x^2 \\ 0 &= 3x^2 + 2x - 1. \end{aligned}$$

Using the quadratic formula,

$$x = \frac{-2 \pm \sqrt{(-2)^2 - 4(3)(-1)}}{6} = \frac{-2 \pm \sqrt{16}}{6} = -1, \frac{1}{3},$$

so the only critical number on the interval $(0, 1)$ is $1/3$. For $0 < x < 1/3$, $f'(x) < 0$, so f is decreasing on the interval $(0, 1/3)$; for $1/3 < x < 1$, $f'(x) > 0$, so f is increasing on the interval $(1/3, 1)$. By the First Derivative Test, it follows that f has a local minimum value at $1/3$. The local minimum value is $f(1/3) = 18$.

113. Let $y = \sqrt{3} \sin x + \cos x$, and consider the interval $0 \leq x \leq 2\pi$. Because the function y is differentiable everywhere, local extrema can only occur where $y'(x) = 0$. Now,

$$y'(x) = \sqrt{3} \cos x - \sin x,$$

so $y'(x) = 0$ when $\tan x = \sqrt{3}$, which is when $x = \frac{\pi}{3}$ and when $x = \frac{4\pi}{3}$. For $0 < x < \frac{\pi}{3}$, $y'(x) > 0$, so y is increasing on the interval $(0, \frac{\pi}{3})$; for $\frac{\pi}{3} < x < \frac{4\pi}{3}$, $y'(x) < 0$, so y is decreasing on the interval $(\frac{\pi}{3}, \frac{4\pi}{3})$; and for $\frac{4\pi}{3} < x < 2\pi$, $y'(x) > 0$, so y is increasing on the interval $(\frac{4\pi}{3}, 2\pi)$. By the First

Derivative Test, it follows that y has a local maximum value at $\frac{\pi}{3}$ and a local minimum value at $\frac{4\pi}{3}$.

The local maximum value is $f\left(\frac{\pi}{3}\right) = 2$, and the local minimum value is $f\left(\frac{4\pi}{3}\right) = -2$.

Next,

$$y''(x) = -\sqrt{3}\sin x - \cos x,$$

so $y''(x) = 0$ when $\tan x = -\frac{\sqrt{3}}{3}$, which is when $x = \frac{5\pi}{6}$ and when $x = \frac{11\pi}{6}$. For $0 < x < \frac{5\pi}{6}$, $y''(x) < 0$, so y is concave down on the interval $\left(0, \frac{5\pi}{6}\right)$; for $\frac{5\pi}{6} < x < \frac{11\pi}{6}$, $y''(x) > 0$, so y is concave up on the interval $\left(\frac{5\pi}{6}, \frac{11\pi}{6}\right)$; and for $\frac{11\pi}{6} < x < 2\pi$, $y''(x) < 0$, so y is concave down on the interval $\left(\frac{11\pi}{6}, 2\pi\right)$. Because the concavity of y changes at $\frac{5\pi}{6}$ and $\frac{11\pi}{6}$, the points

$\left(\frac{5\pi}{6}, f\left(\frac{5\pi}{6}\right)\right) = \left(\frac{5\pi}{6}, 0\right)$ and $\left(\frac{11\pi}{6}, f\left(\frac{11\pi}{6}\right)\right) = \left(\frac{11\pi}{6}, 0\right)$ are points of inflection of y .

114. Let $n > 1$ and consider the function $f(x) = x^n - n(x-1) - 1$ for $x > 0$. Now,

$$f'(x) = nx^{n-1} - n = n(x^{n-1} - 1),$$

so 1 is a critical number of f . For $0 < x < 1$, $f'(x) < 0$, so f is decreasing on the interval $(0, 1)$, and for $x > 1$, $f'(x) > 0$, so f is increasing on the interval $(1, \infty)$. It follows that $f(x)$ is always greater than or equal to $f(1) = 1 - n(0) - 1 = 0$. Therefore,

the expression $x^n - n(x-1) - 1$ can never be negative for $x > 0$ and $n > 1$.

115. Let $f(x) = x^{2/3}$. Then

$$f'(x) = \frac{2}{3}x^{-1/3} \quad \text{and} \quad f''(x) = -\frac{2}{9}x^{-4/3}.$$

It follows that 0 is the only critical number of f , but $f''(x)$ does not exist at 0; therefore, the Second Derivative Test cannot be applied to identify the extreme value of $f(x) = x^{2/3}$.

116. Let $f(x) = x^2 + e^{-2x}$. Then $f'(x) = 2x - 2e^{-2x} = 2(x - e^{-2x})$ and $f''(x) = 2 + 4e^{-2x}$. The figure below displays the graphs of $y = x$ (the solid curve) and $y = e^{-2x}$ (the dashed curve). Let x^* denote the x -coordinate of the point of intersection between the two curves.

- (a) **False**. Based on the graph above, $x > e^{-2x}$ for $x > x^*$, so $f'(x) > 0$ and f is increasing on the interval (x^*, ∞) .
- (b) **False**. Based on the graph above, $x < e^{-2x}$ for $x < x^*$, so $f'(x) < 0$ and f is decreasing on the interval $(-\infty, x^*)$.
- (c) **False**. As f is the sum of two functions that are continuous everywhere, f is continuous everywhere.
- (d) **True**. Because $e^{-2x} > 0$ for all x , $f''(x) = 2 + 4e^{-2x} > 2 > 0$ for all x . Therefore, f is concave up for all x .
- (e) **False**. As noted in part (d), f is concave up for all x .
117. (a) **Not necessarily true**. The figure below displays a function f that is continuous for all x and has a local maximum at $(-1, 4)$ and a local minimum at $(3, -2)$, but does not have a point of inflection somewhere between $x = -1$ and $x = 3$.

- (b) **Not necessarily true**. See the graph in part (a) for which $f'(-1)$ does not exist.
- (c) **Not necessarily true**. See the graph in part (a) which does not have a horizontal asymptote.
- (d) **Not necessarily true**. See the graph in part (a) which does not have a tangent line at $x = 3$.
- (e) **True**. The function is continuous for all x , so $f(0)$ is defined, meaning the graph of f has a y -intercept, and the graph of f intersects the y -axis. Moreover, because f is continuous on the closed interval $[-1, 3]$ with $f(-1) = 4 > 0$ and $f(3) = -2 < 0$, the Intermediate Value Theorem guarantees there exists a c in $(-1, 3)$ such that $f(c) = 0$. Therefore, the graph of f intersects the x -axis as well.
118. Let $f(x) = ax^2 + bx + c$, where $a \neq 0$. The polynomial function f is differentiable everywhere, so critical numbers occur where $f'(x) = 0$. Now,

$$f'(x) = 2ax + b = 0 \quad \text{when} \quad x = -\frac{b}{2a}.$$

Moreover, $f''(x) = 2a$. It follows that when $a < 0$, $f''(x) = 2a < 0$ for all x and f has a local maximum at $-\frac{b}{2a}$ by the Second Derivative Test. On the other hand, when $a > 0$, $f''(x) = 2a > 0$ for all x and f has a local minimum at $-\frac{b}{2a}$ by the Second Derivative Test.

119. Consider the function $f(x) = x - \sin x$. Now,

$$f'(x) = 1 + \cos x \geq 0$$

on the interval $0 \leq x \leq 2\pi$. Therefore, f is increasing on the interval $0 \leq x \leq 2\pi$, so $f(x) \geq f(0) = 0$ on the interval $0 \leq x \leq 2\pi$. That is, $x - \sin x \geq 0$, or $x \geq \sin x$ on the interval $0 \leq x \leq 2\pi$.

120. Consider the function $f(x) = \cos x - 1 + \frac{x^2}{2}$. Now,

$$f'(x) = -\sin x + x \geq 0$$

on the interval $0 \leq x \leq 2\pi$ by the result of Problem 119. Therefore, f is increasing on the interval $0 \leq x \leq 2\pi$, so $f(x) \geq f(0) = 0$ on the interval $0 \leq x \leq 2\pi$. That is, $\cos x - 1 + \frac{x^2}{2} \geq 0$, or $\cos x \geq 1 - \frac{x^2}{2}$ on the interval $0 \leq x \leq 2\pi$.

121. Let $f(x) = 2\sqrt{x} - 3 + \frac{1}{x}$. Now,

$$f'(x) = \frac{1}{\sqrt{x}} - \frac{1}{x^2}.$$

For $x > 1$,

$$x^2 > \sqrt{x} \quad \text{so that} \quad \frac{1}{x^2} < \frac{1}{\sqrt{x}}.$$

It follows that $f'(x) > 0$ and f is increasing for $x > 1$. Therefore, $f(x) > f(1) = 0$ for $x > 1$; that is,

$$2\sqrt{x} - 3 + \frac{1}{x} > 0 \quad \text{or} \quad 2\sqrt{x} > 3 - \frac{1}{x}$$

for $x > 1$.

122. Let $f(x) = x^2 - 8x + 21$. Then $f'(x) = 2x - 8 = 2(x - 4)$, and 4 is the only critical number of f . For $x < 4$, $f'(x) < 0$, so f is decreasing on the interval $(-\infty, 4)$; for $x > 4$, $f'(x) > 0$, so f is increasing on the interval $(4, \infty)$. It follows that $f(x) \geq f(4)$ for all x . Now, $f(4) = 5$, so $f(x) \geq 5 > 0$ for all x .

123. Let $f(x) = 3x^4 - 4x^3 - 12x^2 + 40$. Then

$$f'(x) = 12x^3 - 12x^2 - 24x = 12x(x^2 - x - 2) = 12x(x + 1)(x - 2),$$

so -1 , 0 , and 2 are critical numbers of f . Consider the closed interval $[-1, 2]$. Evaluating f at -1 , 0 , and 2 yields

$$f(-1) = 35, \quad f(0) = 40, \quad \text{and} \quad f(2) = 8,$$

so the absolute minimum value of f on the interval $[-1, 2]$ is 8. For $x < -1$, $f'(x) < 0$, so f is decreasing on the interval $(-\infty, -1)$. This means that $f(x) \geq f(-1) = 35$ for $x < -1$. Moreover, for $x > 2$, $f'(x) > 0$, so f is increasing on the interval $(2, \infty)$. This means that $f(x) > f(2) = 8$ for $x > 2$. Bringing all of this information together, it follows that f has an absolute minimum value of 8 at 2. Therefore, $f(x) \geq 8 > 0$ for all x .

124. Let $f(x) = ax^2 + bx + c$, where $a \neq 0$. Then $f'(x) = 2ax + b$ and $f''(x) = 2a$. If $a < 0$, then $f''(x) = 2a < 0$ for all x , so f is concave down for all x ; if $a > 0$, then $f''(x) = 2a > 0$ for all x , so f is concave up for all x . Because the concavity of f never changes, the function f has no points of inflection.

125. Let $f(x) = ax^3 + bx^2 + cx + d$, where $a \neq 0$. Then $f'(x) = 3ax^2 + 2bx + c$ and $f''(x) = 6ax + 2b$, so $f''(x) = 0$ when $x = -\frac{b}{3a}$. If $a < 0$, then

$$f''(x) > 0 \text{ when } x < -\frac{b}{3a} \quad \text{and} \quad f''(x) < 0 \text{ when } x > -\frac{b}{3a},$$

so the concavity of f changes and there is a point of inflection at $-\frac{b}{3a}$; if $a > 0$, then

$$f''(x) < 0 \text{ when } x < -\frac{b}{3a} \quad \text{and} \quad f''(x) > 0 \text{ when } x > -\frac{b}{3a},$$

so, again, the concavity of f changes and there is a point of inflection at $-\frac{b}{3a}$. Therefore, every polynomial of degree 3 has exactly one point of inflection.

126. Let f be a polynomial of degree $n \geq 3$. Because the polynomial function f is differentiable everywhere, critical numbers can only occur where $f'(x) = 0$. Now, $f'(x)$ is a polynomial of degree $n - 1 \geq 2$, so there are at most $n - 1$ critical numbers. Moreover, the only candidates for points of inflection are where $f''(x) = 0$; but, $f''(x)$ is a polynomial of degree $n - 2 \geq 1$, so there are at most $n - 2$ points of inflection.

127. Let $f(x) = (x - a)^n$, where a is a constant and $n \geq 3$ is an odd integer. Then,

$$f'(x) = n(x - a)^{n-1} \quad \text{and} \quad f''(x) = n(n - 1)(x - a)^{n-2},$$

so $f''(x)$ exists everywhere and is equal to zero only for $x = a$. Because n is an odd integer, $n - 2$ is also an odd integer, so $f''(x) < 0$ for $x < a$ and $f''(x) > 0$ for $x > a$. It follows that the concavity of f changes and f has a point of inflection at a . There are no other candidates for points of inflection, so the function f has exactly one point of inflection.

128. Let $f(x) = (x - a)^n$, where a is a constant and $n \geq 2$ is an even integer. Then,

$$f'(x) = n(x - a)^{n-1} \quad \text{and} \quad f''(x) = n(n - 1)(x - a)^{n-2},$$

so $f''(x)$ exists everywhere and is equal to zero only for $x = a$. Because n is an even integer, $n - 2$ is also an even integer, so $f''(x) > 0$ for all $x \neq a$. Therefore, the concavity of f never changes, and f has no points of inflection.

129. Consider the function $f(x) = \frac{ax + b}{ax + d}$. The rational function f is differentiable on its domain, so critical numbers occur only when $f'(x) = 0$ and points of inflection can only occur when $f''(x) = 0$. Now,

$$f'(x) = \frac{(ax + d)(a) - (ax + b)(a)}{(ax + d)^2} = \frac{a(d - b)}{(ax + d)^2},$$

and

$$f''(x) = -\frac{2a^2(d - b)}{(ax + d)^3}.$$

Provided $a \neq 0$ and $d \neq b$, $f'(x)$ and $f''(x)$ are never equal to zero, so the function f has no critical numbers and no points of inflection. If $a = 0$ or $d = b$, then f is a constant function so that all real numbers x are critical numbers but f still has no points of inflection.

130. Let f be a continuous function on some interval I . Suppose c is a critical number of f and (a, b) is some open interval in I containing c with $f'(x) < 0$ for $a < x < c$ and $f'(x) > 0$ for $c < x < b$. Then the function f is decreasing on the interval (a, c) and increasing on the interval (c, b) ; in other words, for all x in (a, b) , $f(x) \geq f(c)$. Therefore, $f(c)$ is a local minimum value.
131. Let f be a continuous function on some interval I . Suppose c is a critical number of f and (a, b) is some open interval in I containing c with $f'(x)$ having the same sign on both sides of c . If $f'(x) < 0$ on the intervals (a, c) and (c, b) , then f is decreasing on both intervals. This implies that $f(x) \geq f(c)$ on the interval (a, c) but $f(x) \leq f(c)$ on the interval (c, b) . On the other hand, if $f'(x) > 0$ on the intervals (a, c) and (c, b) , then f is increasing on both intervals. This implies that $f(x) \leq f(c)$ on the interval (a, c) but $f(x) \geq f(c)$ on the interval (c, b) . In either case, $f(c)$ is neither a local maximum value nor a local minimum value.
132. Let f be a function that is continuous on the closed interval $[a, b]$. Moreover, suppose that f' and f'' exist on the open interval (a, b) with $f''(x) < 0$ on (a, b) . Let c be any fixed number in (a, b) . An equation of the tangent line to f at the point $(c, f(c))$ is

$$y = f(c) + f'(c)(x - c).$$

To show that f is concave down on (a, b) , it must be established that the graph of f lies below each of its tangent lines for all x in (a, b) ; that is, that

$$f(x) \leq f(c) + f'(c)(x - c)$$

for all x in (a, b) . If $x = c$, then $f(x) = f(c)$ and there is nothing more to prove. If $x \neq c$, then by applying the Mean Value Theorem to the function f , there is a number x_1 between c and x for which

$$f'(x_1) = \frac{f(x) - f(c)}{x - c}.$$

Solve this equation for $f(x)$ to obtain $f(x) = f(c) + f'(x_1)(x - c)$. There are two cases to consider:

- Case I: $c < x_1 < x$: Because $f''(x) < 0$ on the interval (a, b) , it follows that f' is decreasing on (a, b) . For $x_1 > c$, this means that $f'(x_1) < f'(c)$. Multiplying by $x - c$, which is positive, and adding $f(c)$ then yields

$$f(x) = f(c) + f'(x_1)(x - c) < f(c) + f'(c)(x - c);$$

that is, the graph of f lies below each of its tangent lines to the right of c in (a, b) .

- Case II: $x < x_1 < c$: Because $f''(x) < 0$ on the interval (a, b) , it follows that f' is decreasing on (a, b) . For $x_1 < c$, this means that $f'(x_1) > f'(c)$. Multiplying by $x - c$, which is negative, and adding $f(c)$ then yields

$$f(x) = f(c) + f'(x_1)(x - c) < f(c) + f'(c)(x - c);$$

that is, the graph of f lies below each of its tangent lines to the left of c in (a, b) .

Therefore, f is concave down.

133. Let f be a function for which f' and f'' exist on an open interval (a, b) , and let $c \in (a, b)$ be a critical number of f . Suppose $f''(c) > 0$. Then

$$f''(c) = \lim_{x \rightarrow c} \frac{f'(x) - f'(c)}{x - c} > 0,$$

so there is an open interval about c for which

$$\frac{f'(x) - f'(c)}{x - c} > 0$$

everywhere in the interval, except possibly at c itself. Because f' exists at c and c is a critical number of f , $f'(c) = 0$, so

$$\frac{f'(x)}{x - c} > 0.$$

For $x < c$ on this interval, $f'(x) < 0$, while for $x > c$ on this interval, $f'(x) > 0$. By the First Derivative Test, it follows that $f(c)$ is a local minimum value.

Challenge Problems

134. Let $f(x) = (x + 1)\tan^{-1} x$. Then

$$f'(x) = (x + 1) \cdot \frac{1}{1 + x^2} + \tan^{-1} x = \frac{x + 1}{1 + x^2} + \tan^{-1} x,$$

and

$$f''(x) = \frac{(1 + x^2) \cdot 1 - (x + 1)(2x)}{(1 + x^2)^2} + \frac{1}{1 + x^2} = \frac{1 + x^2 - 2x^2 - 2x}{(1 + x^2)^2} + \frac{1 + x^2}{(1 + x^2)^2} = \frac{2 - 2x}{(1 + x^2)^2},$$

so $f''(x)$ exists everywhere and is equal to zero when $x = 1$. For $x < 1$, $f''(x) > 0$, so f is concave up on the interval $(-\infty, 1)$; for $x > 1$, $f''(x) < 0$, so f is concave down on the interval $(1, \infty)$. Because

the concavity of f changes at 1, the point $\boxed{(1, f(1)) = \left(1, \frac{\pi}{2}\right)}$ is a point of inflection of f .

135. Let $f(x) = (1+x)^n - (1+nx)$, where $n > 1$ and $x \neq 0$. Then

$$f'(x) = n(1+x)^{n-1} - n = n((1+x)^{n-1} - 1).$$

If $-1 < x < 0$, then $0 < 1+x < 1$ and $(1+x)^{n-1} < 1$ so $f'(x) < 0$. This means that f is decreasing on the interval $(-1, 0)$, so that $f(x) > f(0)$ for $-1 < x < 0$. On the other hand, if $x > 0$, then $1+x > 1$ and $(1+x)^{n-1} > 1$, so $f'(x) > 0$. This means that f is increasing on the interval $(0, \infty)$, so that $f(x) > f(0)$ for $x > 0$. Therefore, for $x > -1$, $x \neq 0$, it follows that $f(x) > f(0)$; equivalently,

$$(1+x)^n - (1+nx) > 0 \quad \text{or} \quad (1+x)^n > 1+nx.$$

4.5: Indeterminate Forms and L'Hôpital's Rule

Concepts and Vocabulary

1. False. $\frac{f(x)}{g(x)}$ is an indeterminate form at c of the type $\frac{0}{0}$ if $\lim_{x \rightarrow c} f(x) = 0$ and $\lim_{x \rightarrow c} g(x) = 0$.
2. False. If $\frac{f(x)}{g(x)}$ is an indeterminate form at c of the type $\frac{0}{0}$, then L'Hôpital's Rule states that

$$\lim_{x \rightarrow c} \frac{f(x)}{g(x)} = \lim_{x \rightarrow c} \frac{\frac{d}{dx} f(x)}{\frac{d}{dx} g(x)}.$$

3. False. $\frac{1}{x}$ is not an indeterminate form at 0 because, in the numerator, $\lim_{x \rightarrow 0} 1 = 1 \neq 0$.
4. False. $x \ln x$ is an indeterminate form at 0^+ of the type $0 \cdot \infty$ because $\lim_{x \rightarrow 0^+} x = 0$ and $\lim_{x \rightarrow 0^+} \ln x = -\infty$.
5. Answers will vary, but here is one possible response. Suppose

$$\lim_{x \rightarrow c} f(x) = \infty \quad \text{and} \quad \lim_{x \rightarrow c} g(x) = \infty.$$

The following argument would also hold if both limits were $-\infty$. Consider the expression $f(x) - g(x)$ as x approaches c . If the value of f becomes unbounded faster than the value of g , the value of $f(x) - g(x)$ should approach ∞ , whereas if the value of g becomes unbounded faster than the value of f , the value of $f(x) - g(x)$ should approach $-\infty$. Moreover, if f and g become unbounded at similar rates, there could be cancellation leading the value of $f(x) - g(x)$ to approach any real number. In other words, in an expression of the form $\infty - \infty$, there is competition between the two terms in the expression, and an analysis of these competing forces is needed to determine the value of the limit. This is why $\infty - \infty$ is an indeterminate form.

Next, consider the expression $f(x) + g(x)$. In this expression, there is no competition between the two terms. The values of f and g are working together to make the value of $f(x) + g(x)$ approach ∞ . This is why $\infty + \infty$ is not an indeterminate form.

6. Answers will vary, but here is one possible response. Remember that the notation $0 \cdot \infty$ refers to a limit for which the value of one factor is *approaching* 0 and the value of the other factor is *approaching* ∞ and not to multiplication of the number 0 and a quantity that is becoming unbounded. If the value of the first factor approaches 0 faster than the value of the second factor becomes unbounded, the value of the product will approach 0; however, if the value of the second factor becomes unbounded faster than the value of the first factor approaches 0, the value of the product will become unbounded. Additionally, if the values of the two factors change at similar rates, the value of the product could approach any real number. Therefore, $0 \cdot \infty$ is an indeterminate form.

Skill Building

7. (a) Because

$$\lim_{x \rightarrow 0} (1 - e^x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} x = 0,$$

the expression $\frac{1 - e^x}{x}$ is an indeterminate form at 0.

- (b) Based on the limits in part (a), the expression $\frac{1 - e^x}{x}$ is an indeterminate form at 0 of the type $\frac{0}{0}$.

8. (a) Because

$$\lim_{x \rightarrow 0} (1 - e^x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} (x - 1) = -1 \neq 0,$$

the expression $\frac{1 - e^x}{x}$ is not an indeterminate form at 0.

- (b) The value of a limit of the form $\frac{0}{-1}$ approaches 0, so it is not an indeterminate form at 0.

9. (a) Because

$$\lim_{x \rightarrow 0} e^x = 1 \neq 0 \quad \text{and} \quad \lim_{x \rightarrow 0} x = 0,$$

the expression $\frac{e^x}{x}$ is not an indeterminate form at 0.

- (b) The value of a limit of the form $\frac{1}{0}$ approaches $\pm\infty$, so it is not an indeterminate form at 0.

10. (a) Because

$$\lim_{x \rightarrow \infty} e^x = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} x = \infty,$$

the expression $\frac{e^x}{x}$ is an indeterminate form at ∞ .

- (b) Based on the limits in part (a), the expression $\frac{e^x}{x}$ is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$.

11. (a) Because

$$\lim_{x \rightarrow \infty} \ln x = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} x^2 = \infty,$$

the expression $\frac{\ln x}{x^2}$ is an indeterminate form at ∞ .

- (b) Based on the limits in part (a), the expression $\frac{\ln x}{x^2}$ is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$.

12. (a) Because

$$\lim_{x \rightarrow 0} \ln(x + 1) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} (e^x - 1) = 0,$$

the expression $\frac{\ln(x + 1)}{e^x - 1}$ is an indeterminate form at 0.

- (b) Based on the limits in part (a), the expression $\frac{\ln(x + 1)}{e^x - 1}$ is an indeterminate form at 0 of the type $\frac{0}{0}$.

13. (a) Because

$$\lim_{x \rightarrow 0} \sec x = 1 \neq 0 \quad \text{and} \quad \lim_{x \rightarrow 0} x = 0,$$

the expression $\frac{\sec x}{x}$ is not an indeterminate form at 0.

- (b) The value of a limit of the form $\frac{1}{0}$ approaches $\pm\infty$, so it is not an indeterminate form at 0.

14. (a) Because

$$\lim_{x \rightarrow 0} x = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} (\sec x - 1) = 0,$$

the expression $\frac{x}{\sec x - 1}$ is an indeterminate form at 0.

- (b) Based on the limits in part (a), the expression $\frac{x}{\sec x - 1}$ is an indeterminate form at 0 of the type $\frac{0}{0}$.

15. (a) Because

$$\lim_{x \rightarrow 0^+} [\sin x(1 - \cos x)] = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} x^2 = 0,$$

the expression $\frac{\sin x(\cos x - 1)}{x^2}$ is an indeterminate form at 0.

- (b) Based on the limits in part (a), the expression $\frac{\sin x(\cos x - 1)}{x^2}$ is an indeterminate form at 0 of the type $\frac{0}{0}$.

16. (a) Because

$$\lim_{x \rightarrow \frac{\pi}{2}} (\sin x - 1) = 0 \quad \text{and} \quad \lim_{x \rightarrow \frac{\pi}{2}} \cos x = 0,$$

the expression $\frac{(\sin x - 1)}{\cos x}$ is an indeterminate form at $\frac{\pi}{2}$.

- (b) Based on the limits in part (a), the expression $\frac{(\sin x - 1)}{\cos x}$ is an indeterminate form at $\frac{\pi}{2}$ of the type $\frac{0}{0}$.

17. (a) Because

$$\lim_{x \rightarrow \frac{\pi}{4}} (\tan x - 1) = 0 \quad \text{and} \quad \lim_{x \rightarrow \frac{\pi}{4}} \sin(4x - \pi) = 0,$$

the expression $\frac{(\tan x - 1)}{\sin(4x - \pi)}$ is an indeterminate form at $\frac{\pi}{4}$.

- (b) Based on the limits in part (a), the expression $\frac{(\tan x - 1)}{\sin(4x - \pi)}$ is an indeterminate form at $\frac{\pi}{4}$ of the type $\frac{0}{0}$.

18. (a) Because

$$\lim_{x \rightarrow 0} (e^x - e^{-x}) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} (1 - \cos x) = 0,$$

the expression $\frac{e^x - e^{-x}}{1 - \cos x}$ is an indeterminate form at 0.

- (b) Based on the limits in part (a), the expression $\frac{e^x - e^{-x}}{1 - \cos x}$ is an indeterminate form at 0 of the type $\frac{0}{0}$.

19. (a) Because

$$\lim_{x \rightarrow \infty} x^2 = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} e^{-x} = 0,$$

the expression $x^2 e^{-x}$ is an indeterminate form at ∞ .

- (b) Based on the limits in part (a), the expression $x^2 e^{-x}$ is an indeterminate form at ∞ of the type $0 \cdot \infty$.

20. (a) Because

$$\lim_{x \rightarrow 0^-} x = 0 \quad \text{and} \quad \lim_{x \rightarrow 0^-} \cot x = -\infty,$$

the expression $x \cot x$ is an indeterminate form at 0^- . Additionally,

$$\lim_{x \rightarrow 0^+} x = 0 \quad \text{and} \quad \lim_{x \rightarrow 0^+} \cot x = \infty,$$

so the expression $x \cot x$ is also an indeterminate form at 0^+ . Therefore, the expression $x \cot x$ is an indeterminate form at 0.

- (b) Based on the limits in part (a), the expression $x \cot x$ is an indeterminate form at 0 of the type $0 \cdot \infty$.

21. (a) Because

$$\lim_{x \rightarrow 0^-} \csc \frac{x}{2} = -\infty \quad \text{and} \quad \lim_{x \rightarrow 0^-} \cot \frac{x}{2} = -\infty,$$

the expression $\csc \frac{x}{2} - \cot \frac{x}{2}$ is an indeterminate form at 0^- . Additionally,

$$\lim_{x \rightarrow 0^+} \csc \frac{x}{2} = \infty \quad \text{and} \quad \lim_{x \rightarrow 0^+} \cot \frac{x}{2} = \infty,$$

so the expression $\csc \frac{x}{2} - \cot \frac{x}{2}$ is also an indeterminate form at 0^+ . Therefore, the expression $\csc \frac{x}{2} - \cot \frac{x}{2}$ is an indeterminate form at 0.

- (b) Based on the limits in part (a), the expression $\csc \frac{x}{2} - \cot \frac{x}{2}$ is an indeterminate form at 0 of the type $\infty - \infty$.

22. (a) Because

$$\lim_{x \rightarrow 1^-} \frac{x}{x-1} = -\infty \quad \text{and} \quad \lim_{x \rightarrow 1^-} \frac{1}{\ln x} = -\infty,$$

the expression $\frac{x}{x-1} + \frac{1}{\ln x}$ at 1^- is of the form $-\infty + (-\infty)$, which is not an indeterminate form. On the other hand,

$$\lim_{x \rightarrow 1^+} \frac{x}{x-1} = \infty \quad \text{and} \quad \lim_{x \rightarrow 1^+} \frac{1}{\ln x} = \infty,$$

so the expression $\frac{x}{x-1} + \frac{1}{\ln x}$ at 1^+ is of the form $\infty + \infty$, which is again not an indeterminate form. Therefore, the expression $\frac{x}{x-1} + \frac{1}{\ln x}$ is not an indeterminate form at 1.

- (b) The value of a limit of the form $-\infty + (-\infty)$ becomes unbounded in the negative direction; the value of a limit of the form $\infty + \infty$ becomes unbounded in the positive direction. Therefore, neither is an indeterminate form.

23. (a) Because

$$\lim_{x \rightarrow 0} \frac{1}{x^2} = \infty \quad \text{and} \quad \lim_{x \rightarrow 0} \sin x = 0,$$

the expression $\left(\frac{1}{x^2}\right)^{\sin x}$ is an indeterminate form at 0.

- (b) Based on the limits in part (a), the expression $\left(\frac{1}{x^2}\right)^{\sin x}$ is an indeterminate form at 0 of the type ∞^0 .

24. (a) Because

$$\lim_{x \rightarrow 0^-} (e^x + x) = 1 \quad \text{and} \quad \lim_{x \rightarrow 0^-} \frac{1}{x} = -\infty,$$

the expression $(e^x + x)^{1/x}$ is an indeterminate form at 0^- . Additionally,

$$\lim_{x \rightarrow 0^+} (e^x + x) = 1 \quad \text{and} \quad \lim_{x \rightarrow 0^+} \frac{1}{x} = \infty,$$

so the expression $(e^x + x)^{1/x}$ is also an indeterminate form at 0^+ . Therefore, the expression $(e^x + x)^{1/x}$ is an indeterminate form at 0.

- (b) Based on the limits in part (a), the expression $(e^x + x)^{1/x}$ is an indeterminate form at 0 of the type 1^∞ .

25. (a) Because

$$\lim_{x \rightarrow 0} (x^2 - 1) = -1 \quad \text{and} \quad \lim_{x \rightarrow 0} x = 0,$$

the expression $(x^2 - 1)^x$ is not an indeterminate form at 0.

- (b) The value of a limit of the form $(-1)^0$ approaches 1, so it is not an indeterminate form at 0.

26. (a) Because

$$\lim_{x \rightarrow 0} \sin x = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} x = 0,$$

the expression $(\sin x)^x$ is an indeterminate form at 0.

- (b) Based on the limits in part (a), the expression $(\sin x)^x$ is an indeterminate form at 0 of the type 0^0 .

27. Because

$$\lim_{x \rightarrow 2} (x^2 + x - 6) = 0 \quad \text{and} \quad \lim_{x \rightarrow 2} (x^2 - 3x + 2) = 0,$$

the expression $\frac{x^2 + x - 6}{x^2 - 3x + 2}$ is an indeterminate form at 2 of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 2} \frac{x^2 + x - 6}{x^2 - 3x + 2} = \lim_{x \rightarrow 2} \frac{\frac{d}{dx}(x^2 + x - 6)}{\frac{d}{dx}(x^2 - 3x + 2)} = \lim_{x \rightarrow 2} \frac{2x + 1}{2x - 3} = \frac{5}{1} = 5.$$

28. Because

$$\lim_{x \rightarrow 1} (2x^3 + 5x^2 - 4x - 3) = 0 \quad \text{and} \quad \lim_{x \rightarrow 1} (x^3 + x^2 - 10x + 8) = 0,$$

the expression $\frac{2x^3 + 5x^2 - 4x - 3}{x^3 + x^2 - 10x + 8}$ is an indeterminate form at 1 of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 1} \frac{2x^3 + 5x^2 - 4x - 3}{x^3 + x^2 - 10x + 8} = \lim_{x \rightarrow 1} \frac{\frac{d}{dx}(2x^3 + 5x^2 - 4x - 3)}{\frac{d}{dx}(x^3 + x^2 - 10x + 8)} = \lim_{x \rightarrow 1} \frac{6x^2 + 10x - 4}{3x^2 + 2x - 10} = \frac{12}{-5} = -\frac{12}{5}.$$

29. Because

$$\lim_{x \rightarrow 1} \ln x = 0 \quad \text{and} \quad \lim_{x \rightarrow 1} (x^2 - 1) = 0,$$

the expression $\frac{\ln x}{x^2 - 1}$ is an indeterminate form at 1 of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 1} \frac{\ln x}{x^2 - 1} = \lim_{x \rightarrow 1} \frac{\frac{d}{dx} \ln x}{\frac{d}{dx}(x^2 - 1)} = \lim_{x \rightarrow 1} \frac{\frac{1}{x}}{2x} = \frac{1}{2}.$$

30. Because

$$\lim_{x \rightarrow 0} \ln(1-x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} (e^x - 1) = 0,$$

the expression $\frac{\ln(1-x)}{e^x - 1}$ is an indeterminate form at 0 of the type $\left[\frac{0}{0}\right]$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 0} \frac{\ln(1-x)}{e^x - 1} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx} \ln(1-x)}{\frac{d}{dx} (e^x - 1)} = \lim_{x \rightarrow 0} \frac{\frac{-1}{1-x}}{e^x} = \frac{-1}{1} = \boxed{-1}.$$

31. Because

$$\lim_{x \rightarrow 0} (e^x - e^{-x}) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} \sin x = 0,$$

the expression $\frac{e^x - e^{-x}}{\sin x}$ is an indeterminate form at 0 of the type $\left[\frac{0}{0}\right]$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 0} \frac{e^x - e^{-x}}{\sin x} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx} (e^x - e^{-x})}{\frac{d}{dx} \sin x} = \lim_{x \rightarrow 0} \frac{e^x + e^{-x}}{\cos x} = \frac{2}{1} = \boxed{2}.$$

32. Because

$$\lim_{x \rightarrow 0} \tan(2x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} \ln(1+x) = 0,$$

the expression $\frac{\tan(2x)}{\ln(1+x)}$ is an indeterminate form at 0 of the type $\left[\frac{0}{0}\right]$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 0} \frac{\tan(2x)}{\ln(1+x)} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx} \tan(2x)}{\frac{d}{dx} \ln(1+x)} = \lim_{x \rightarrow 0} \frac{2 \sec^2(2x)}{\frac{1}{1+x}} = \frac{2}{1} = \boxed{2}.$$

33. Because

$$\lim_{x \rightarrow 1} \sin(\pi x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 1} (x-1) = 0,$$

the expression $\frac{\sin(\pi x)}{x-1}$ is an indeterminate form at 1 of the type $\left[\frac{0}{0}\right]$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 1} \frac{\sin(\pi x)}{x-1} = \lim_{x \rightarrow 1} \frac{\frac{d}{dx} \sin(\pi x)}{\frac{d}{dx} (x-1)} = \lim_{x \rightarrow 1} \frac{\pi \cos(\pi x)}{1} = \boxed{-\pi}.$$

34. Because

$$\lim_{x \rightarrow \pi} (1 + \cos x) = 0 \quad \text{and} \quad \lim_{x \rightarrow \pi} \sin(2x) = 0,$$

the expression $\frac{1 + \cos x}{\sin(2x)}$ is an indeterminate form at π of the type $\left[\frac{0}{0}\right]$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow \pi} \frac{1 + \cos x}{\sin(2x)} = \lim_{x \rightarrow \pi} \frac{\frac{d}{dx} (1 + \cos x)}{\frac{d}{dx} \sin(2x)} = \lim_{x \rightarrow \pi} \frac{-\sin x}{2 \cos(2x)} = \frac{0}{2} = \boxed{0}.$$

35. Because

$$\lim_{x \rightarrow \infty} x^2 = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} e^x = \infty,$$

the expression $\frac{x^2}{e^x}$ is an indeterminate form at ∞ of the type $\left[\frac{\infty}{\infty}\right]$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow \infty} \frac{x^2}{e^x} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx} x^2}{\frac{d}{dx} e^x} = \lim_{x \rightarrow \infty} \frac{2x}{e^x}.$$

Because

$$\lim_{x \rightarrow \infty} (2x) = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} e^x = \infty,$$

the expression $\frac{2x}{e^x}$ is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule again,

$$\lim_{x \rightarrow \infty} \frac{x^2}{e^x} = \lim_{x \rightarrow \infty} \frac{2x}{e^x} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx}(2x)}{\frac{d}{dx}e^x} = \lim_{x \rightarrow \infty} \frac{2}{e^x} = \boxed{0}.$$

36. Because

$$\lim_{x \rightarrow \infty} e^x = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} x^4 = \infty,$$

the expression $\frac{e^x}{x^4}$ is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow \infty} \frac{e^x}{x^4} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx}e^x}{\frac{d}{dx}x^4} = \lim_{x \rightarrow \infty} \frac{e^x}{4x^3}.$$

Because

$$\lim_{x \rightarrow \infty} e^x = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} (4x^3) = \infty,$$

the expression $\frac{e^x}{4x^3}$ is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule again,

$$\lim_{x \rightarrow \infty} \frac{e^x}{x^4} = \lim_{x \rightarrow \infty} \frac{e^x}{4x^3} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx}e^x}{\frac{d}{dx}(4x^3)} = \lim_{x \rightarrow \infty} \frac{e^x}{12x^2}.$$

Now,

$$\lim_{x \rightarrow \infty} e^x = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} (12x^2) = \infty,$$

so the expression $\frac{e^x}{12x^2}$ is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule for a third time,

$$\lim_{x \rightarrow \infty} \frac{e^x}{x^4} = \lim_{x \rightarrow \infty} \frac{e^x}{12x^2} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx}e^x}{\frac{d}{dx}(12x^2)} = \lim_{x \rightarrow \infty} \frac{e^x}{24x}.$$

Finally, because

$$\lim_{x \rightarrow \infty} e^x = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} (24x) = \infty,$$

the expression $\frac{e^x}{24x}$ is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule for a fourth time,

$$\lim_{x \rightarrow \infty} \frac{e^x}{x^4} = \lim_{x \rightarrow \infty} \frac{e^x}{24x} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx}e^x}{\frac{d}{dx}(24x)} = \lim_{x \rightarrow \infty} \frac{e^x}{24} = \boxed{\infty}.$$

37. Because

$$\lim_{x \rightarrow \infty} \ln x = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} e^x = \infty,$$

the expression $\frac{\ln x}{e^x}$ is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow \infty} \frac{\ln x}{e^x} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx} \ln x}{\frac{d}{dx} e^x} = \lim_{x \rightarrow \infty} \frac{\frac{1}{x}}{e^x} = \boxed{0}.$$

38. Because

$$\lim_{x \rightarrow \infty} (x + \ln x) = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} (x \ln x) = \infty,$$

the expression $\frac{x + \ln x}{x \ln x}$ is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow \infty} \frac{x + \ln x}{x \ln x} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx}(x + \ln x)}{\frac{d}{dx}(x \ln x)} = \lim_{x \rightarrow \infty} \frac{1 + \frac{1}{x}}{x \cdot \frac{1}{x} + \ln x} = \lim_{x \rightarrow \infty} \frac{1 + \frac{1}{x}}{1 + \ln x} = \boxed{0}.$$

39. Because

$$\lim_{x \rightarrow 0} (e^x - 1 - \sin x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} (1 - \cos x) = 0,$$

the expression $\frac{e^x - 1 - \sin x}{1 - \cos x}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 0} \frac{e^x - 1 - \sin x}{1 - \cos x} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx}(e^x - 1 - \sin x)}{\frac{d}{dx}(1 - \cos x)} = \lim_{x \rightarrow 0} \frac{e^x - \cos x}{\sin x}.$$

Because

$$\lim_{x \rightarrow 0} (e^x - \cos x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} \sin x = 0,$$

the expression $\frac{e^x - \cos x}{\sin x}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule again,

$$\lim_{x \rightarrow 0} \frac{e^x - 1 - \sin x}{1 - \cos x} = \lim_{x \rightarrow 0} \frac{e^x - \cos x}{\sin x} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx}(e^x - \cos x)}{\frac{d}{dx} \sin x} = \lim_{x \rightarrow 0} \frac{e^x + \sin x}{\cos x} = \frac{1}{1} = \boxed{1}.$$

40. Because

$$\lim_{x \rightarrow 0} (e^x - e^{-x} - 2 \sin x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} (3x^3) = 0,$$

the expression $\frac{e^x - e^{-x} - 2 \sin x}{3x^3}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 0} \frac{e^x - e^{-x} - 2 \sin x}{3x^3} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx}(e^x - e^{-x} - 2 \sin x)}{\frac{d}{dx}(3x^3)} = \lim_{x \rightarrow 0} \frac{e^x + e^{-x} - 2 \cos x}{9x^2}.$$

Because

$$\lim_{x \rightarrow 0} (e^x + e^{-x} - 2 \cos x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} (9x^2) = 0,$$

the expression $\frac{e^x + e^{-x} - 2 \cos x}{9x^2}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule again,

$$\begin{aligned} \lim_{x \rightarrow 0} \frac{e^x - e^{-x} - 2 \sin x}{3x^3} &= \lim_{x \rightarrow 0} \frac{e^x + e^{-x} - 2 \cos x}{9x^2} \\ &= \lim_{x \rightarrow 0} \frac{\frac{d}{dx}(e^x + e^{-x} - 2 \cos x)}{\frac{d}{dx}(9x^2)} = \lim_{x \rightarrow 0} \frac{e^x - e^{-x} + 2 \sin x}{18x}. \end{aligned}$$

Now,

$$\lim_{x \rightarrow 0} (e^x - e^{-x} + 2 \sin x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} (18x) = 0,$$

so the expression $\frac{e^x - e^{-x} + 2 \sin x}{18x}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's rule for a third time,

$$\begin{aligned} \lim_{x \rightarrow 0} \frac{e^x - e^{-x} - 2 \sin x}{3x^3} &= \lim_{x \rightarrow 0} \frac{e^x - e^{-x} + 2 \sin x}{18x} \\ &= \lim_{x \rightarrow 0} \frac{\frac{d}{dx}(e^x - e^{-x} + 2 \sin x)}{\frac{d}{dx}(18x)} = \lim_{x \rightarrow 0} \frac{e^x + e^{-x} + 2 \cos x}{18} = \frac{4}{18} = \boxed{\frac{2}{9}}. \end{aligned}$$

41. Because

$$\lim_{x \rightarrow 0} (\sin x - x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} x^3 = 0,$$

the expression $\frac{\sin x - x}{x^3}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 0} \frac{\sin x - x}{x^3} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx}(\sin x - x)}{\frac{d}{dx}x^3} = \lim_{x \rightarrow 0} \frac{\cos x - 1}{3x^2}.$$

Because

$$\lim_{x \rightarrow 0} (\cos x - 1) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} (3x^2) = 0,$$

the expression $\frac{\cos x - 1}{3x^2}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule again,

$$\lim_{x \rightarrow 0} \frac{\sin x - x}{x^3} = \lim_{x \rightarrow 0} \frac{\cos x - 1}{3x^2} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx}(\cos x - 1)}{\frac{d}{dx}(3x^2)} = \lim_{x \rightarrow 0} \frac{-\sin x}{6x}.$$

Now,

$$\lim_{x \rightarrow 0} (-\sin x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} (6x) = 0,$$

so the expression $\frac{-\sin x}{6x}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's rule for a third time,

$$\lim_{x \rightarrow 0} \frac{\sin x - x}{x^3} = \lim_{x \rightarrow 0} \frac{-\sin x}{6x} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx}(-\sin x)}{\frac{d}{dx}(6x)} = \lim_{x \rightarrow 0} \frac{-\cos x}{6} = \boxed{-\frac{1}{6}}.$$

42. Because

$$\lim_{x \rightarrow 0} x^3 = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} (\cos x - 1) = 0,$$

the expression $\frac{x^3}{\cos x - 1}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 0} \frac{x^3}{\cos x - 1} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx}x^3}{\frac{d}{dx}(\cos x - 1)} = \lim_{x \rightarrow 0} \frac{3x^2}{-\sin x}.$$

Because

$$\lim_{x \rightarrow 0} (3x^2) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} (-\sin x) = 0,$$

the expression $\frac{3x^2}{-\sin x}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule again,

$$\lim_{x \rightarrow 0} \frac{x^3}{\cos x - 1} = \lim_{x \rightarrow 0} \frac{3x^2}{-\sin x} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx}(3x^2)}{\frac{d}{dx}(-\sin x)} = \lim_{x \rightarrow 0} \frac{6x}{-\cos x} = \frac{0}{-1} = \boxed{0}.$$

43. Because

$$\lim_{x \rightarrow 0^+} x^2 = 0 \quad \text{and} \quad \lim_{x \rightarrow 0^+} \ln x = -\infty,$$

the expression $x^2 \ln x$ is an indeterminate form at 0^+ of the type $0 \cdot \infty$. Rewrite

$$x^2 \ln x \quad \text{as} \quad \frac{\ln x}{\frac{1}{x^2}} = \frac{\ln x}{x^{-2}},$$

which is an indeterminate form at 0^+ of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 0^+} (x^2 \ln x) = \lim_{x \rightarrow 0^+} \frac{\ln x}{x^{-2}} = \lim_{x \rightarrow 0^+} \frac{\frac{d}{dx} \ln x}{\frac{d}{dx} x^{-2}} = \lim_{x \rightarrow 0^+} \frac{\frac{1}{x}}{-2x^{-3}} = \lim_{x \rightarrow 0^+} \frac{x^2}{-2} = \boxed{0}.$$

44. Because

$$\lim_{x \rightarrow \infty} x = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} e^{-x} = 0,$$

the expression xe^{-x} is an indeterminate form at ∞ of the type $\boxed{0 \cdot \infty}$. Rewrite

$$xe^{-x} \quad \text{as} \quad \frac{x}{e^x},$$

which is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow \infty} (xe^{-x}) = \lim_{x \rightarrow \infty} \frac{x}{e^x} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx}x}{\frac{d}{dx}e^x} = \lim_{x \rightarrow \infty} \frac{1}{e^x} = \boxed{0}.$$

45. Because

$$\lim_{x \rightarrow \infty} x = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} (e^{1/x} - 1) = 0,$$

the expression $x(e^{1/x} - 1)$ is an indeterminate form at ∞ of the type $\boxed{0 \cdot \infty}$. Rewrite

$$x(e^{1/x} - 1) \quad \text{as} \quad \frac{e^{1/x} - 1}{1/x},$$

which is an indeterminate form at ∞ of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow \infty} [x(e^{1/x} - 1)] = \lim_{x \rightarrow \infty} \frac{e^{1/x} - 1}{1/x} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx}(e^{1/x} - 1)}{\frac{d}{dx}(1/x)} = \lim_{x \rightarrow \infty} \frac{-x^{-2}e^{1/x}}{-x^{-2}} = \lim_{x \rightarrow \infty} e^{1/x} = e^0 = \boxed{1}.$$

46. Because

$$\lim_{x \rightarrow \pi/2^-} (1 - \sin x) = 0 \quad \text{and} \quad \lim_{x \rightarrow \pi/2^-} \tan x = \infty,$$

while

$$\lim_{x \rightarrow \pi/2^+} (1 - \sin x) = 0 \quad \text{and} \quad \lim_{x \rightarrow \pi/2^+} \tan x = -\infty,$$

the expression $(1 - \sin x) \tan x$ is an indeterminate form at $\pi/2$ of the type $\boxed{0 \cdot \infty}$. Rewrite

$$(1 - \sin x) \tan x \quad \text{as} \quad \frac{1 - \sin x}{\cot x},$$

which is an indeterminate form at $\pi/2$ of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow \pi/2} [(1 - \sin x) \tan x] = \lim_{x \rightarrow \pi/2} \frac{1 - \sin x}{\cot x} = \lim_{x \rightarrow \pi/2} \frac{\frac{d}{dx}(1 - \sin x)}{\frac{d}{dx} \cot x} = \lim_{x \rightarrow \pi/2} \frac{-\cos x}{-\csc^2 x} = \frac{0}{-1} = \boxed{0}.$$

47. Because

$$\lim_{x \rightarrow \pi/2^-} \sec x = \infty \quad \text{and} \quad \lim_{x \rightarrow \pi/2^-} \tan x = \infty,$$

while

$$\lim_{x \rightarrow \pi/2^+} \sec x = -\infty \quad \text{and} \quad \lim_{x \rightarrow \pi/2^+} \tan x = -\infty,$$

the expression $\sec x - \tan x$ is an indeterminate form at $\pi/2$ of the type $\boxed{\infty - \infty}$. Rewrite

$$\sec x - \tan x \quad \text{as} \quad \frac{1}{\cos x} - \frac{\sin x}{\cos x} = \frac{1 - \sin x}{\cos x},$$

which is an indeterminate form at $\pi/2$ of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow \pi/2} (\sec x - \tan x) = \lim_{x \rightarrow \pi/2} \frac{1 - \sin x}{\cos x} = \lim_{x \rightarrow \pi/2} \frac{\frac{d}{dx}(1 - \sin x)}{\frac{d}{dx} \cos x} = \lim_{x \rightarrow \pi/2} \frac{-\cos x}{-\sin x} = \frac{0}{-1} = \boxed{0}.$$

48. Because

$$\lim_{x \rightarrow 0^-} \cot x = -\infty \quad \text{and} \quad \lim_{x \rightarrow 0^-} \frac{1}{x} = -\infty,$$

while

$$\lim_{x \rightarrow 0^+} \cot x = \infty \quad \text{and} \quad \lim_{x \rightarrow 0^+} \frac{1}{x} = \infty,$$

the expression $\cot x - \frac{1}{x}$ is an indeterminate form at 0 of the type $\boxed{\infty - \infty}$. Rewrite

$$\cot x - \frac{1}{x} \quad \text{as} \quad \frac{\cos x}{\sin x} - \frac{1}{x} = \frac{x \cos x - \sin x}{x \sin x},$$

which is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\begin{aligned} \lim_{x \rightarrow 0} \left(\cot x - \frac{1}{x} \right) &= \lim_{x \rightarrow 0} \frac{x \cos x - \sin x}{x \sin x} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx}(x \cos x - \sin x)}{\frac{d}{dx}(x \sin x)} \\ &= \lim_{x \rightarrow 0} \frac{-x \sin x + \cos x - \cos x}{x \cos x + \sin x} = \lim_{x \rightarrow 0} \frac{-x \sin x}{x \cos x + \sin x}. \end{aligned}$$

Now,

$$\lim_{x \rightarrow 0} (-x \sin x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} (x \cos x + \sin x) = 0,$$

so the expression $\frac{-x \sin x}{x \cos x + \sin x}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule again,

$$\begin{aligned} \lim_{x \rightarrow 0} \left(\cot x - \frac{1}{x} \right) &= \lim_{x \rightarrow 0} \frac{-x \sin x}{x \cos x + \sin x} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx}(-x \sin x)}{\frac{d}{dx}(x \cos x + \sin x)} \\ &= \lim_{x \rightarrow 0} \frac{-x \cos x - \sin x}{-x \sin x + \cos x + \cos x} = \frac{0}{2} = \boxed{0}. \end{aligned}$$

49. Because

$$\lim_{x \rightarrow 1^-} \frac{1}{\ln x} = -\infty \quad \text{and} \quad \lim_{x \rightarrow 1^-} \frac{x}{\ln x} = -\infty,$$

while

$$\lim_{x \rightarrow 1^+} \frac{1}{\ln x} = \infty \quad \text{and} \quad \lim_{x \rightarrow 1^+} \frac{x}{\ln x} = \infty,$$

the expression $\frac{1}{\ln x} - \frac{x}{\ln x}$ is an indeterminate form at 1 of the type $\boxed{\infty - \infty}$. Rewrite

$$\frac{1}{\ln x} - \frac{x}{\ln x} \quad \text{as} \quad \frac{1-x}{\ln x},$$

which is an indeterminate form at 1 of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 1} \left(\frac{1}{\ln x} - \frac{x}{\ln x} \right) = \lim_{x \rightarrow 1} \frac{1-x}{\ln x} = \lim_{x \rightarrow 1} \frac{\frac{d}{dx}(1-x)}{\frac{d}{dx} \ln x} = \lim_{x \rightarrow 1} \frac{-1}{\frac{1}{x}} = \frac{-1}{1} = \boxed{-1}.$$

50. Because

$$\lim_{x \rightarrow 0^-} \frac{1}{x} = -\infty \quad \text{and} \quad \lim_{x \rightarrow 0^-} \frac{1}{e^x - 1} = -\infty,$$

while

$$\lim_{x \rightarrow 0^+} \frac{1}{x} = \infty \quad \text{and} \quad \lim_{x \rightarrow 0^+} \frac{1}{e^x - 1} = \infty,$$

the expression $\frac{1}{x} - \frac{1}{e^x - 1}$ is an indeterminate form at 0 of the type $\boxed{\infty - \infty}$. Rewrite

$$\frac{1}{x} - \frac{1}{e^x - 1} \quad \text{as} \quad \frac{e^x - 1 - x}{x(e^x - 1)},$$

which is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 0} \left(\frac{1}{x} - \frac{1}{e^x - 1} \right) = \lim_{x \rightarrow 0} \frac{e^x - 1 - x}{x(e^x - 1)} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx}(e^x - 1 - x)}{\frac{d}{dx}[x(e^x - 1)]} = \lim_{x \rightarrow 0} \frac{e^x - 1}{xe^x + e^x - 1}.$$

Now,

$$\lim_{x \rightarrow 0} (e^x - 1) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} (xe^x + e^x - 1) = 0,$$

so the expression $\frac{e^x - 1}{xe^x + e^x - 1}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule again,

$$\lim_{x \rightarrow 0} \left(\frac{1}{x} - \frac{1}{e^x - 1} \right) = \lim_{x \rightarrow 0} \frac{e^x - 1}{xe^x + e^x - 1} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx}(e^x - 1)}{\frac{d}{dx}(xe^x + e^x - 1)} = \lim_{x \rightarrow 0} \frac{e^x}{xe^x + e^x + e^x} = \boxed{\frac{1}{2}}.$$

51. Because

$$\lim_{x \rightarrow 0^+} (2x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0^+} (3x) = 0,$$

the expression $(2x)^{3x}$ is an indeterminate form at 0^+ of the type $\boxed{0^0}$. Let $y = (2x)^{3x}$. Then

$$\ln y = \ln(2x)^{3x} = (3x) \ln(2x),$$

which is an indeterminate form at 0^+ of the type $0 \cdot \infty$. Rewrite

$$(3x) \ln(2x) \quad \text{as} \quad \frac{\ln(2x)}{\frac{1}{3x}},$$

which is now an indeterminate form at 0^+ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\begin{aligned} \lim_{x \rightarrow 0^+} \ln y &= \lim_{x \rightarrow 0^+} [(3x) \ln(2x)] = \lim_{x \rightarrow 0^+} \frac{\ln(2x)}{\frac{1}{3x}} = \lim_{x \rightarrow 0^+} \frac{\frac{d}{dx} \ln(2x)}{\frac{d}{dx} \frac{1}{3x}} \\ &= \lim_{x \rightarrow 0^+} \frac{\frac{1}{2x} \cdot 2}{-\frac{1}{(3x)^2} \cdot 3} = \lim_{x \rightarrow 0^+} (-3x) = 0. \end{aligned}$$

Finally, because $\lim_{x \rightarrow 0^+} \ln y = 0$, it follows that

$$\lim_{x \rightarrow 0^+} y = \lim_{x \rightarrow 0^+} (2x)^{3x} = e^0 = \boxed{1}.$$

52. Because

$$\lim_{x \rightarrow 0^+} x = 0 \quad \text{and} \quad \lim_{x \rightarrow 0^+} x^2 = 0,$$

the expression x^{x^2} is an indeterminate form at 0 of the type $\boxed{0^0}$. Let $y = x^{x^2}$. Then

$$\ln y = \ln(x^{x^2}) = x^2 \ln x,$$

which is an indeterminate form at 0^+ of the type $0 \cdot \infty$. Rewrite

$$x^2 \ln x \quad \text{as} \quad \frac{\ln x}{\frac{1}{x^2}} = \frac{\ln x}{x^{-2}},$$

which is now an indeterminate form at 0^+ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 0^+} \ln y = \lim_{x \rightarrow 0^+} (x^2 \ln x) = \lim_{x \rightarrow 0^+} \frac{\ln x}{x^{-2}} = \lim_{x \rightarrow 0^+} \frac{\frac{d}{dx} \ln x}{\frac{d}{dx} x^{-2}} = \lim_{x \rightarrow 0^+} \frac{\frac{1}{x}}{-2x^{-3}} = \lim_{x \rightarrow 0^+} \frac{x^2}{-2} = 0.$$

Finally, because $\lim_{x \rightarrow 0^+} \ln y = 0$, it follows that

$$\lim_{x \rightarrow 0^+} y = \lim_{x \rightarrow 0^+} x^{x^2} = e^0 = \boxed{1}.$$

53. Because

$$\lim_{x \rightarrow \infty} (x+1) = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} e^{-x} = 0,$$

the expression $(x+1)^{e^{-x}}$ is an indeterminate form at ∞ of the type $\boxed{\infty^0}$. Let $y = (x+1)^{e^{-x}}$. Then

$$\ln y = \ln(x+1)^{e^{-x}} = e^{-x} \ln(x+1),$$

which is an indeterminate form at ∞ of the type $0 \cdot \infty$. Rewrite

$$e^{-x} \ln(x+1) \quad \text{as} \quad \frac{\ln(1+x)}{e^x},$$

which is now an indeterminate form ∞ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow \infty} \ln y = \lim_{x \rightarrow \infty} [e^{-x} \ln(1+x)] = \lim_{x \rightarrow \infty} \frac{\ln(1+x)}{e^x} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx} \ln(1+x)}{\frac{d}{dx} e^x} = \lim_{x \rightarrow \infty} \frac{\frac{1}{1+x}}{e^x} = 0.$$

Finally, because $\lim_{x \rightarrow \infty} \ln y = 0$, it follows that

$$\lim_{x \rightarrow \infty} y = \lim_{x \rightarrow \infty} (x+1)^{e^{-x}} = e^0 = \boxed{1}.$$

54. Because

$$\lim_{x \rightarrow \infty} (1+x^2) = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} \frac{1}{x} = 0,$$

the expression $(1+x^2)^{1/x}$ is an indeterminate form at ∞ of the type $\boxed{\infty^0}$. Let $y = (1+x^2)^{1/x}$. Then

$$\ln y = \ln(1+x^2)^{1/x} = \frac{1}{x} \ln(1+x^2) = \frac{\ln(1+x^2)}{x},$$

which is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow \infty} \ln y = \lim_{x \rightarrow \infty} \frac{\ln(1+x^2)}{x} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx} \ln(1+x^2)}{\frac{d}{dx} x} = \lim_{x \rightarrow \infty} \frac{\frac{2x}{1+x^2}}{1} = 0.$$

Finally, because $\lim_{x \rightarrow \infty} \ln y = 0$, it follows that

$$\lim_{x \rightarrow \infty} y = \lim_{x \rightarrow \infty} (1+x^2)^{1/x} = e^0 = \boxed{1}.$$

55. Because

$$\lim_{x \rightarrow 0^+} \csc x = \infty \quad \text{and} \quad \lim_{x \rightarrow 0^+} \sin x = 0,$$

the expression $(\csc x)^{\sin x}$ is an indeterminate form at 0^+ of the type $\boxed{\infty^0}$. Let $y = (\csc x)^{\sin x}$. Then

$$\ln y = \ln(\csc x)^{\sin x} = \sin x \ln(\csc x),$$

which is an indeterminate form at 0^+ of the type $0 \cdot \infty$. Rewrite

$$\sin x \ln(\csc x) \quad \text{as} \quad \frac{\ln(\csc x)}{\frac{1}{\sin x}} = \frac{\ln(\csc x)}{\csc x},$$

which is now an indeterminate form at 0^+ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\begin{aligned} \lim_{x \rightarrow 0^+} \ln y &= \lim_{x \rightarrow 0^+} [\sin x \ln(\csc x)] = \lim_{x \rightarrow 0^+} \frac{\ln(\csc x)}{\csc x} = \lim_{x \rightarrow 0^+} \frac{\frac{d}{dx} \ln(\csc x)}{\frac{d}{dx} \csc x} \\ &= \lim_{x \rightarrow 0^+} \frac{\sin x \cdot -\csc x \cot x}{-\csc x \cot x} = \lim_{x \rightarrow 0^+} \sin x = 0. \end{aligned}$$

Finally, because $\lim_{x \rightarrow 0^+} \ln y = 0$, it follows that

$$\lim_{x \rightarrow 0^+} y = \lim_{x \rightarrow 0^+} (\csc x)^{\sin x} = e^0 = \boxed{1}.$$

56. Because

$$\lim_{x \rightarrow \infty} x = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} \frac{1}{x} = 0,$$

the expression $x^{1/x}$ is an indeterminate form at ∞ of the type $\boxed{\infty^0}$. Let $y = x^{1/x}$. Then

$$\ln y = \ln x^{1/x} = \frac{1}{x} \ln x = \frac{\ln x}{x},$$

which is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow \infty} \ln y = \lim_{x \rightarrow \infty} \frac{\ln x}{x} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx} \ln x}{\frac{d}{dx} x} = \lim_{x \rightarrow \infty} \frac{\frac{1}{x}}{1} = 0.$$

Finally, because $\lim_{x \rightarrow \infty} \ln y = 0$, it follows that

$$\lim_{x \rightarrow \infty} y = \lim_{x \rightarrow \infty} x^{1/x} = e^0 = \boxed{1}.$$

57. Because

$$\lim_{x \rightarrow \pi/2^-} \sin x = 1 \quad \text{and} \quad \lim_{x \rightarrow \pi/2^-} \tan x = \infty,$$

the expression $(\sin x)^{\tan x}$ is an indeterminate form at $\pi/2^-$ of the type $\boxed{1^\infty}$. Let $y = (\sin x)^{\tan x}$. Then

$$\ln y = \ln(\sin x)^{\tan x} = \tan x \ln(\sin x),$$

which is an indeterminate form at $\pi/2^-$ of the type $0 \cdot \infty$. Rewrite

$$\tan x \ln(\sin x) \quad \text{as} \quad \frac{\ln(\sin x)}{\cot x},$$

which is now an indeterminate form at $\pi/2^-$ of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\begin{aligned} \lim_{x \rightarrow \pi/2^-} \ln y &= \lim_{x \rightarrow \pi/2^-} [\tan x \ln(\sin x)] = \lim_{x \rightarrow \pi/2^-} \frac{\ln(\sin x)}{\cot x} \\ &= \lim_{x \rightarrow \pi/2^-} \frac{\frac{d}{dx} \ln(\sin x)}{\frac{d}{dx} \cot x} = \lim_{x \rightarrow \pi/2^-} \frac{\frac{1}{\sin x} \cdot \cos x}{-\csc^2 x} = \lim_{x \rightarrow \pi/2^-} (-\sin x \cos x) = 0. \end{aligned}$$

Finally, because $\lim_{x \rightarrow \pi/2^-} \ln y = 0$, it follows that

$$\lim_{x \rightarrow \pi/2^-} y = \lim_{x \rightarrow \pi/2^-} (\sin x)^{\tan x} = e^0 = \boxed{1}.$$

58. Because

$$\lim_{x \rightarrow 0^-} \cos x = 1 \quad \text{and} \quad \lim_{x \rightarrow 0^-} \frac{1}{x} = -\infty,$$

while

$$\lim_{x \rightarrow 0^+} \cos x = 1 \quad \text{and} \quad \lim_{x \rightarrow 0^+} \frac{1}{x} = \infty,$$

the expression $(\cos x)^{1/x}$ is an indeterminate form at 0 of the type $\boxed{1^\infty}$. Let $y = (\cos x)^{1/x}$. Then

$$\ln y = \ln(\cos x)^{1/x} = \frac{1}{x} \ln(\cos x) = \frac{\ln(\cos x)}{x},$$

which is now an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 0} \ln y = \lim_{x \rightarrow 0} \frac{\ln(\cos x)}{x} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx} \ln(\cos x)}{\frac{d}{dx} x} = \lim_{x \rightarrow 0} \frac{\frac{1}{\cos x} \cdot -\sin x}{1} = 0.$$

Finally, because $\lim_{x \rightarrow 0} \ln y = 0$, it follows that

$$\lim_{x \rightarrow 0} y = \lim_{x \rightarrow 0} (\cos x)^{1/x} = e^0 = \boxed{1}.$$

59. Note that

$$\frac{\cot x}{\cot(2x)} = \frac{\tan(2x)}{\tan x};$$

because

$$\lim_{x \rightarrow 0^+} \tan(2x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0^+} \tan x = 0,$$

the expression $\frac{\tan(2x)}{\tan x}$ is an indeterminate form at 0^+ of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 0^+} \frac{\cot x}{\cot(2x)} = \lim_{x \rightarrow 0^+} \frac{\tan(2x)}{\tan x} = \lim_{x \rightarrow 0^+} \frac{\frac{d}{dx} \tan(2x)}{\frac{d}{dx} \tan x} = \lim_{x \rightarrow 0^+} \frac{2 \sec^2(2x)}{\sec^2 x} = \frac{2}{1} = \boxed{2}.$$

60. Because

$$\lim_{x \rightarrow \infty} \ln(\ln x) = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} \ln x = \infty,$$

the expression $\frac{\ln(\ln x)}{\ln x}$ is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow \infty} \frac{\ln(\ln x)}{\ln x} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx} \ln(\ln x)}{\frac{d}{dx} \ln x} = \lim_{x \rightarrow \infty} \frac{\frac{1}{\ln x} \cdot \frac{1}{x}}{\frac{1}{x}} = \lim_{x \rightarrow \infty} \frac{1}{\ln x} = \boxed{0}.$$

61. Because

$$\lim_{x \rightarrow 1/2^-} \ln(1 - 2x) = -\infty \quad \text{and} \quad \lim_{x \rightarrow 1/2^-} \tan(\pi x) = \infty,$$

the expression $\frac{\ln(1 - 2x)}{\tan(\pi x)}$ is an indeterminate form at $1/2^-$ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 1/2^-} \frac{\ln(1 - 2x)}{\tan(\pi x)} = \lim_{x \rightarrow 1/2^-} \frac{\frac{d}{dx} \ln(1 - 2x)}{\frac{d}{dx} \tan(\pi x)} = \lim_{x \rightarrow 1/2^-} \frac{\frac{1}{1-2x} \cdot -2}{\pi \sec^2(\pi x)} = \lim_{x \rightarrow 1/2^-} \frac{-2 \cos^2(\pi x)}{\pi(1 - 2x)}.$$

Now,

$$\lim_{x \rightarrow 1/2^-} [-2 \cos^2(\pi x)] = 0 \quad \text{and} \quad \lim_{x \rightarrow 1/2^-} [\pi(1 - 2x)] = 0,$$

so the expression $\frac{-2\cos^2(\pi x)}{\pi(1-2x)}$ is an indeterminate form at $1/2^-$ of the type $\frac{0}{0}$. Using L'Hôpital's Rule again,

$$\begin{aligned}\lim_{x \rightarrow 1/2^-} \frac{\ln(1-2x)}{\tan(\pi x)} &= \lim_{x \rightarrow 1/2^-} \frac{-2\cos^2(\pi x)}{\pi(1-2x)} = \lim_{x \rightarrow 1/2^-} \frac{\frac{d}{dx}[-2\cos^2(\pi x)]}{\frac{d}{dx}[\pi(1-2x)]} \\ &= \lim_{x \rightarrow 1/2^-} \frac{-4\pi \cos(\pi x) \cdot -\sin(\pi x)}{-2\pi} = \lim_{x \rightarrow 1/2^-} [-2\sin(\pi x) \cos(\pi x)] = \boxed{0}.\end{aligned}$$

62. Because

$$\lim_{x \rightarrow 1^-} \ln(1-x) = -\infty \quad \text{and} \quad \lim_{x \rightarrow 1^-} \cot(\pi x) = -\infty,$$

the expression $\frac{\ln(1-x)}{\cot(\pi x)}$ is an indeterminate form at 1^- of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 1^-} \frac{\ln(1-x)}{\cot(\pi x)} = \lim_{x \rightarrow 1^-} \frac{\frac{d}{dx} \ln(1-x)}{\frac{d}{dx} \cot(\pi x)} = \lim_{x \rightarrow 1^-} \frac{\frac{1}{1-x} \cdot -1}{-\pi \csc^2(\pi x)} = \lim_{x \rightarrow 1^-} \frac{\sin^2(\pi x)}{\pi(1-x)}.$$

Now,

$$\lim_{x \rightarrow 1^-} \sin^2(\pi x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 1^-} [\pi(1-x)] = 0,$$

so the expression $\frac{\sin^2(\pi x)}{\pi(1-x)}$ is an indeterminate form at 1^- of the type $\frac{0}{0}$. Using L'Hôpital's Rule again,

$$\begin{aligned}\lim_{x \rightarrow 1^-} \frac{\ln(1-x)}{\cot(\pi x)} &= \lim_{x \rightarrow 1^-} \frac{\sin^2(\pi x)}{\pi(1-x)} = \lim_{x \rightarrow 1^-} \frac{\frac{d}{dx} \sin^2(\pi x)}{\frac{d}{dx} [\pi(1-x)]} \\ &= \lim_{x \rightarrow 1^-} \frac{2\pi \sin(\pi x) \cos(\pi x)}{-\pi} = \lim_{x \rightarrow 1^-} [-2\sin(\pi x) \cos(\pi x)] = \boxed{0}.\end{aligned}$$

63. Because

$$\lim_{x \rightarrow \infty} (x^4 + x^3) = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} (e^x + 1) = \infty,$$

the expression $\frac{x^4 + x^3}{e^x + 1}$ is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow \infty} \frac{x^4 + x^3}{e^x + 1} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx}(x^4 + x^3)}{\frac{d}{dx}(e^x + 1)} = \lim_{x \rightarrow \infty} \frac{4x^3 + 3x^2}{e^x}.$$

Because

$$\lim_{x \rightarrow \infty} (4x^3 + 3x^2) = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} e^x = \infty,$$

the expression $\frac{4x^3 + 3x^2}{e^x}$ is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule again,

$$\lim_{x \rightarrow \infty} \frac{x^4 + x^3}{e^x + 1} = \lim_{x \rightarrow \infty} \frac{4x^3 + 3x^2}{e^x} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx}(4x^3 + 3x^2)}{\frac{d}{dx} e^x} = \lim_{x \rightarrow \infty} \frac{12x^2 + 6x}{e^x}.$$

Now,

$$\lim_{x \rightarrow \infty} (12x^2 + 6x) = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} e^x = \infty,$$

so the expression $\frac{12x^2 + 6x}{e^x}$ is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule a third time,

$$\lim_{x \rightarrow \infty} \frac{x^4 + x^3}{e^x + 1} = \lim_{x \rightarrow \infty} \frac{12x^2 + 6x}{e^x} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx}(12x^2 + 6x)}{\frac{d}{dx} e^x} = \lim_{x \rightarrow \infty} \frac{24x + 6}{e^x}.$$

Finally, because

$$\lim_{x \rightarrow \infty} (24x + 6) = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} e^x = \infty,$$

the expression $\frac{24x + 6}{e^x}$ is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule a fourth time,

$$\lim_{x \rightarrow \infty} \frac{x^4 + x^3}{e^x + 1} = \lim_{x \rightarrow \infty} \frac{24x + 6}{e^x} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx}(24x + 6)}{\frac{d}{dx}e^x} = \lim_{x \rightarrow \infty} \frac{24}{e^x} = \boxed{0}.$$

64. Because

$$\lim_{x \rightarrow \infty} (x^2 + x - 1) = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} (e^x + e^{-x}) = \infty,$$

the expression $\frac{x^2 + x - 1}{e^x + e^{-x}}$ is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow \infty} \frac{x^2 + x - 1}{e^x + e^{-x}} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx}(x^2 + x - 1)}{\frac{d}{dx}(e^x + e^{-x})} = \lim_{x \rightarrow \infty} \frac{2x + 1}{e^x - e^{-x}}.$$

Now,

$$\lim_{x \rightarrow \infty} (2x + 1) = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} (e^x - e^{-x}) = \infty,$$

so the expression $\frac{2x + 1}{e^x - e^{-x}}$ is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule again,

$$\lim_{x \rightarrow \infty} \frac{x^2 + x - 1}{e^x + e^{-x}} = \lim_{x \rightarrow \infty} \frac{2x + 1}{e^x - e^{-x}} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx}(2x + 1)}{\frac{d}{dx}(e^x - e^{-x})} = \lim_{x \rightarrow \infty} \frac{2}{e^x + e^{-x}} = \boxed{0}.$$

65. Because

$$\lim_{x \rightarrow 0} (xe^{4x} - x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} [1 - \cos(2x)] = 0,$$

the expression $\frac{xe^{4x} - x}{1 - \cos(2x)}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 0} \frac{xe^{4x} - x}{1 - \cos(2x)} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx}(xe^{4x} - x)}{\frac{d}{dx}[1 - \cos(2x)]} = \lim_{x \rightarrow 0} \frac{4xe^{4x} + e^{4x} - 1}{2 \sin(2x)}.$$

Now,

$$\lim_{x \rightarrow 0} (4xe^{4x} + e^{4x} - 1) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} [2 \sin(2x)] = 0,$$

so the expression $\frac{4xe^{4x} + e^{4x} - 1}{2 \sin(2x)}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule again,

$$\begin{aligned} \lim_{x \rightarrow 0} \frac{xe^{4x} - x}{1 - \cos(2x)} &= \lim_{x \rightarrow 0} \frac{4xe^{4x} + e^{4x} - 1}{2 \sin(2x)} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx}(4xe^{4x} + e^{4x} - 1)}{\frac{d}{dx}[2 \sin(2x)]} \\ &= \lim_{x \rightarrow 0} \frac{16xe^{4x} + 4e^{4x} + 4e^{4x}}{4 \cos(2x)} = \frac{8}{4} = \boxed{2}. \end{aligned}$$

66. Because

$$\lim_{x \rightarrow 0} (x \tan x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} (1 - \cos x) = 0,$$

the expression $\frac{x \tan x}{1 - \cos x}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 0} \frac{x \tan x}{1 - \cos x} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx}(x \tan x)}{\frac{d}{dx}(1 - \cos x)} = \lim_{x \rightarrow 0} \frac{x \sec^2 x + \tan x}{\sin x}.$$

Now,

$$\lim_{x \rightarrow 0} (x \sec^2 x + \tan x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} \sin x = 0,$$

so the expression $\frac{x \sec^2 x + \tan x}{\sin x}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule again,

$$\begin{aligned} \lim_{x \rightarrow 0} \frac{x \tan x}{1 - \cos x} &= \lim_{x \rightarrow 0} \frac{x \sec^2 x + \tan x}{\sin x} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx}(x \sec^2 x + \tan x)}{\frac{d}{dx} \sin x} \\ &= \lim_{x \rightarrow 0} \frac{2x \sec^2 x \tan x + \sec^2 x + \sec^2 x}{\cos x} = \frac{2}{1} = \boxed{2}. \end{aligned}$$

67. Because

$$\lim_{x \rightarrow 0} \tan^{-1} x = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} x = 0,$$

the expression $\frac{\tan^{-1} x}{x}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 0} \frac{\tan^{-1} x}{x} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx} \tan^{-1} x}{\frac{d}{dx} x} = \lim_{x \rightarrow 0} \frac{\frac{1}{1+x^2}}{1} = \frac{1}{1} = \boxed{1}.$$

68. Because

$$\lim_{x \rightarrow 0} \tan^{-1} x = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} \sin^{-1} x = 0,$$

the expression $\frac{\tan^{-1} x}{\sin^{-1} x}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 0} \frac{\tan^{-1} x}{\sin^{-1} x} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx} \tan^{-1} x}{\frac{d}{dx} \sin^{-1} x} = \lim_{x \rightarrow 0} \frac{\frac{1}{1+x^2}}{\frac{1}{\sqrt{1-x^2}}} = \frac{1}{1} = \boxed{1}.$$

69. Because

$$\lim_{x \rightarrow 0} (\cos x - 1) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} [\cos(2x) - 1] = 0,$$

the expression $\frac{\cos x - 1}{\cos(2x) - 1}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 0} \frac{\cos x - 1}{\cos(2x) - 1} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx}(\cos x - 1)}{\frac{d}{dx}[\cos(2x) - 1]} = \lim_{x \rightarrow 0} \frac{-\sin x}{-2 \sin(2x)} = \lim_{x \rightarrow 0} \frac{\sin x}{2 \sin(2x)}.$$

Now,

$$\lim_{x \rightarrow 0} \sin x = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} [2 \sin(2x)] = 0,$$

so the expression $\frac{\sin x}{2 \sin(2x)}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule again,

$$\lim_{x \rightarrow 0} \frac{\cos x - 1}{\cos(2x) - 1} = \lim_{x \rightarrow 0} \frac{\sin x}{2 \sin(2x)} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx} \sin x}{\frac{d}{dx} [2 \sin(2x)]} = \lim_{x \rightarrow 0} \frac{\cos x}{4 \cos(2x)} = \boxed{\frac{1}{4}}.$$

70. Because

$$\lim_{x \rightarrow 0} (\tan x - \sin x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} x^3 = 0,$$

the expression $\frac{\tan x - \sin x}{x^3}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 0} \frac{\tan x - \sin x}{x^3} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx}(\tan x - \sin x)}{\frac{d}{dx} x^3} = \lim_{x \rightarrow 0} \frac{\sec^2 x - \cos x}{3x^2}.$$

Now,

$$\lim_{x \rightarrow 0} (\sec^2 x - \cos x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} (3x^2) = 0,$$

so the expression $\frac{\sec^2 x - \cos x}{3x^2}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule again,

$$\lim_{x \rightarrow 0} \frac{\tan x - \sin x}{x^3} = \lim_{x \rightarrow 0} \frac{\sec^2 x - \cos x}{3x^2} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx}(\sec^2 x - \cos x)}{\frac{d}{dx}(3x^2)} = \lim_{x \rightarrow 0} \frac{2 \sec^2 x \tan x + \sin x}{6x}.$$

Finally,

$$\lim_{x \rightarrow 0} (2 \sec^2 x \tan x + \sin x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} (6x) = 0,$$

so the expression $\frac{2 \sec^2 x \tan x + \sin x}{6x}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule a third time,

$$\begin{aligned} \lim_{x \rightarrow 0} \frac{\tan x - \sin x}{x^3} &= \lim_{x \rightarrow 0} \frac{2 \sec^2 x \tan x + \sin x}{6x} \\ &= \lim_{x \rightarrow 0} \frac{\frac{d}{dx}(2 \sec^2 x \tan x + \sin x)}{\frac{d}{dx}6x} = \lim_{x \rightarrow 0} \frac{2 \sec^4 x + 4 \sec^2 x \tan^2 x + \cos x}{6} = \frac{3}{6} = \boxed{\frac{1}{2}}. \end{aligned}$$

71. Because

$$\lim_{x \rightarrow 0^+} x^{1/2} = 0 \quad \text{and} \quad \lim_{x \rightarrow 0^+} \ln x = -\infty,$$

the expression $x^{1/2} \ln x$ is an indeterminate form at 0^+ of the type $0 \cdot \infty$. Rewrite

$$x^{1/2} \ln x \quad \text{as} \quad \frac{\ln x}{\frac{1}{x^{1/2}}} = \frac{\ln x}{x^{-1/2}},$$

which is an indeterminate form at 0^+ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 0^+} (x^{1/2} \ln x) = \lim_{x \rightarrow 0^+} \frac{\ln x}{x^{-1/2}} = \lim_{x \rightarrow 0^+} \frac{\frac{d}{dx} \ln x}{\frac{d}{dx} x^{-1/2}} = \lim_{x \rightarrow 0^+} \frac{\frac{1}{x}}{-\frac{1}{2} x^{-3/2}} = \lim_{x \rightarrow 0^+} (-2x^{1/2}) = \boxed{0}.$$

72. Because

$$\lim_{x \rightarrow \infty} (x - 1) = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} e^{-x^2} = 0,$$

the expression $(x - 1)e^{-x^2}$ is an indeterminate form at ∞ of the type $0 \cdot \infty$. Rewrite

$$(x - 1)e^{-x^2} \quad \text{as} \quad \frac{x - 1}{e^{x^2}},$$

which is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow \infty} [(x - 1)e^{-x^2}] = \lim_{x \rightarrow \infty} \frac{x - 1}{e^{x^2}} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx}(x - 1)}{\frac{d}{dx} e^{x^2}} = \lim_{x \rightarrow \infty} \frac{1}{2xe^{x^2}} = \boxed{0}.$$

73. Because

$$\lim_{x \rightarrow \pi/2^-} \tan x = \infty \quad \text{and} \quad \lim_{x \rightarrow \pi/2^-} \ln(\sin x) = 0,$$

while

$$\lim_{x \rightarrow \pi/2^+} \tan x = -\infty \quad \text{and} \quad \lim_{x \rightarrow \pi/2^+} \ln(\sin x) = 0,$$

the expression $\tan x \ln(\sin x)$ is an indeterminate form at $\pi/2$ of the type $0 \cdot \infty$. Rewrite

$$\tan x \ln(\sin x) \quad \text{as} \quad \frac{\ln(\sin x)}{\frac{1}{\tan x}} = \frac{\ln(\sin x)}{\cot x},$$

which is an indeterminate form at $\pi/2$ of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\begin{aligned} \lim_{x \rightarrow \pi/2} [\tan x \ln(\sin x)] &= \lim_{x \rightarrow \pi/2} \frac{\ln(\sin x)}{\cot x} = \lim_{x \rightarrow \pi/2} \frac{\frac{d}{dx} \ln(\sin x)}{\frac{d}{dx} \cot x} \\ &= \lim_{x \rightarrow \pi/2} \frac{\frac{1}{\sin x} \cdot \cos x}{-\csc^2 x} = \lim_{x \rightarrow \pi/2} (-\sin x \cos x) = \boxed{0}. \end{aligned}$$

74. Because

$$\lim_{x \rightarrow 0^+} \sin x = 0 \quad \text{and} \quad \lim_{x \rightarrow 0^+} \ln(\sin x) = -\infty,$$

the expression $\sin x \ln(\sin x)$ is an indeterminate form at 0^+ of the type $0 \cdot \infty$. Rewrite

$$\sin x \ln(\sin x) \quad \text{as} \quad \frac{\ln(\sin x)}{\frac{1}{\sin x}} = \frac{\ln(\sin x)}{\csc x},$$

which is an indeterminate form at 0^+ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 0^+} [\sin x \ln(\sin x)] = \lim_{x \rightarrow 0^+} \frac{\ln(\sin x)}{\csc x} = \lim_{x \rightarrow 0^+} \frac{\frac{d}{dx} \ln(\sin x)}{\frac{d}{dx} \csc x} = \lim_{x \rightarrow 0^+} \frac{\frac{1}{\sin x} \cdot \cos x}{-\csc x \cot x} = \lim_{x \rightarrow 0^+} (-\sin x) = \boxed{0}.$$

75. Because

$$\lim_{x \rightarrow 0^-} \csc x = -\infty \quad \text{and} \quad \lim_{x \rightarrow 0^-} \ln(x+1) = 0,$$

while

$$\lim_{x \rightarrow 0^+} \csc x = \infty \quad \text{and} \quad \lim_{x \rightarrow 0^+} \ln(x+1) = 0,$$

the expression $\csc x \ln(x+1)$ is an indeterminate form at 0 of the type $0 \cdot \infty$. Rewrite

$$\csc x \ln(x+1) \quad \text{as} \quad \frac{\ln(x+1)}{\sin x},$$

which is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 0} [\csc x \ln(x+1)] = \lim_{x \rightarrow 0} \frac{\ln(x+1)}{\sin x} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx} \ln(x+1)}{\frac{d}{dx} \sin x} = \lim_{x \rightarrow 0} \frac{\frac{1}{x+1}}{\cos x} = \frac{1}{1} = \boxed{1}.$$

76. Because

$$\lim_{x \rightarrow \pi/4^-} (1 - \tan x) = 0 \quad \text{and} \quad \lim_{x \rightarrow \pi/4^-} \sec(2x) = \infty,$$

while

$$\lim_{x \rightarrow \pi/4^+} (1 - \tan x) = 0 \quad \text{and} \quad \lim_{x \rightarrow \pi/4^+} \sec(2x) = -\infty,$$

the expression $(1 - \tan x) \sec(2x)$ is an indeterminate form at $\pi/4$ of the type $0 \cdot \infty$. Rewrite

$$(1 - \tan x) \sec(2x) \quad \text{as} \quad \frac{1 - \tan x}{\cos(2x)},$$

which is an indeterminate form at $\pi/4$ of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow \pi/4} [(1 - \tan x) \sec(2x)] = \lim_{x \rightarrow \pi/4} \frac{1 - \tan x}{\cos(2x)} = \lim_{x \rightarrow \pi/4} \frac{\frac{d}{dx} (1 - \tan x)}{\frac{d}{dx} \cos(2x)} = \lim_{x \rightarrow \pi/4} \frac{-\sec^2 x}{-2 \sin(2x)} = \frac{-2}{-2} = \boxed{1}.$$

77. Because

$$\lim_{x \rightarrow a^-} (a^2 - x^2) = 0 \quad \text{and} \quad \lim_{x \rightarrow a^-} \tan\left(\frac{\pi x}{2a}\right) = \infty,$$

while

$$\lim_{x \rightarrow a^+} (a^2 - x^2) = 0 \quad \text{and} \quad \lim_{x \rightarrow a^+} \tan\left(\frac{\pi x}{2a}\right) = -\infty,$$

the expression $(a^2 - x^2) \tan\left(\frac{\pi x}{2a}\right)$ is an indeterminate form at a of the type $0 \cdot \infty$. Rewrite

$$(a^2 - x^2) \tan\left(\frac{\pi x}{2a}\right) \quad \text{as} \quad \frac{a^2 - x^2}{\cot\left(\frac{\pi x}{2a}\right)},$$

which is an indeterminate form at a of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow a} \left[(a^2 - x^2) \tan\left(\frac{\pi x}{2a}\right) \right] = \lim_{x \rightarrow a} \frac{a^2 - x^2}{\cot\left(\frac{\pi x}{2a}\right)} = \lim_{x \rightarrow a} \frac{\frac{d}{dx}(a^2 - x^2)}{\frac{d}{dx} \cot\left(\frac{\pi x}{2a}\right)} = \lim_{x \rightarrow a} \frac{-2x}{-\frac{\pi}{2a} \csc^2\left(\frac{\pi x}{2a}\right)} = \frac{-2a}{-\frac{\pi}{2a}} = \boxed{\frac{4a^2}{\pi}}.$$

78. Because

$$\lim_{x \rightarrow 1^+} (1 - x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 1^+} \tan\left(\frac{1}{2}\pi x\right) = -\infty,$$

the expression $(1 - x) \tan\left(\frac{1}{2}\pi x\right)$ is an indeterminate form at 1^+ of the type $0 \cdot \infty$. Rewrite

$$(1 - x) \tan\left(\frac{1}{2}\pi x\right) \quad \text{as} \quad \frac{1 - x}{\cot\left(\frac{1}{2}\pi x\right)},$$

which is an indeterminate form at 1^+ of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\begin{aligned} \lim_{x \rightarrow 1^+} \left[(1 - x) \tan\left(\frac{1}{2}\pi x\right) \right] &= \lim_{x \rightarrow 1^+} \frac{1 - x}{\cot\left(\frac{1}{2}\pi x\right)} = \lim_{x \rightarrow 1^+} \frac{\frac{d}{dx}(1 - x)}{\frac{d}{dx} \cot\left(\frac{1}{2}\pi x\right)} \\ &= \lim_{x \rightarrow 1^+} \frac{-1}{-\frac{1}{2}\pi \csc^2\left(\frac{1}{2}\pi x\right)} = \frac{-1}{-\frac{1}{2}\pi} = \boxed{\frac{2}{\pi}}. \end{aligned}$$

79. Because

$$\lim_{x \rightarrow 1^-} \frac{1}{\ln x} = -\infty \quad \text{and} \quad \lim_{x \rightarrow 1^-} \frac{1}{x - 1} = -\infty,$$

while

$$\lim_{x \rightarrow 1^+} \frac{1}{\ln x} = \infty \quad \text{and} \quad \lim_{x \rightarrow 1^+} \frac{1}{x - 1} = \infty,$$

the expression $\frac{1}{\ln x} - \frac{1}{x - 1}$ is an indeterminate form at 1 of the type $\infty - \infty$. Rewrite

$$\frac{1}{\ln x} - \frac{1}{x - 1} \quad \text{as} \quad \frac{x - 1 - \ln x}{(x - 1) \ln x},$$

which is an indeterminate form at 1 of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\begin{aligned} \lim_{x \rightarrow 1} \left(\frac{1}{\ln x} - \frac{1}{x - 1} \right) &= \lim_{x \rightarrow 1} \frac{x - 1 - \ln x}{(x - 1) \ln x} \\ &= \lim_{x \rightarrow 1} \frac{\frac{d}{dx}(x - 1 - \ln x)}{\frac{d}{dx}[(x - 1) \ln x]} = \lim_{x \rightarrow 1} \frac{1 - \frac{1}{x}}{(x - 1) \cdot \frac{1}{x} + \ln x} = \lim_{x \rightarrow 1} \frac{x - 1}{x - 1 + x \ln x}. \end{aligned}$$

Now,

$$\lim_{x \rightarrow 1} (x - 1) = 0 \quad \text{and} \quad \lim_{x \rightarrow 1} (x - 1 + x \ln x) = 0,$$

so the expression $\frac{x-1}{x-1+x \ln x}$ is an indeterminate form at 1 of the type $\frac{0}{0}$. Using L'Hôpital's Rule again,

$$\lim_{x \rightarrow 1} \left(\frac{1}{\ln x} - \frac{1}{x-1} \right) = \lim_{x \rightarrow 1} \frac{x-1}{x-1+x \ln x} = \lim_{x \rightarrow 1} \frac{\frac{d}{dx}(x-1)}{\frac{d}{dx}(x-1+x \ln x)} = \lim_{x \rightarrow 1} \frac{1}{1+x \cdot \frac{1}{x} + \ln x} = \boxed{\frac{1}{2}}.$$

80. Because

$$\lim_{x \rightarrow 1^-} \frac{x}{x-1} = -\infty \quad \text{and} \quad \lim_{x \rightarrow 1^-} \frac{1}{\ln x} = -\infty,$$

while

$$\lim_{x \rightarrow 1^+} \frac{x}{x-1} = \infty \quad \text{and} \quad \lim_{x \rightarrow 1^+} \frac{1}{\ln x} = \infty,$$

the expression $\frac{x}{x-1} - \frac{1}{\ln x}$ is an indeterminate form at 1 of the type $\infty - \infty$. Rewrite

$$\frac{x}{x-1} - \frac{1}{\ln x} \quad \text{as} \quad \frac{x \ln x - (x-1)}{(x-1) \ln x} = \frac{x \ln x - x + 1}{(x-1) \ln x},$$

which is an indeterminate form at 1 of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\begin{aligned} \lim_{x \rightarrow 1} \left(\frac{x}{x-1} - \frac{1}{\ln x} \right) &= \lim_{x \rightarrow 1} \frac{x \ln x - x + 1}{(x-1) \ln x} \\ &= \lim_{x \rightarrow 1} \frac{\frac{d}{dx}(x \ln x - x + 1)}{\frac{d}{dx}[(x-1) \ln x]} = \lim_{x \rightarrow 1} \frac{x \cdot \frac{1}{x} + \ln x - 1}{(x-1) \cdot \frac{1}{x} + \ln x} = \lim_{x \rightarrow 1} \frac{x \ln x}{x-1+x \ln x}. \end{aligned}$$

Now,

$$\lim_{x \rightarrow 1} (x \ln x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 1} (x-1+x \ln x) = 0,$$

so the expression $\frac{x \ln x}{x-1+x \ln x}$ is an indeterminate form at 1 of the type $\frac{0}{0}$. Using L'Hôpital's Rule again,

$$\lim_{x \rightarrow 1} \left(\frac{x}{x-1} - \frac{1}{\ln x} \right) = \lim_{x \rightarrow 1} \frac{x \ln x}{x-1+x \ln x} = \lim_{x \rightarrow 1} \frac{\frac{d}{dx}(x \ln x)}{\frac{d}{dx}(x-1+x \ln x)} = \lim_{x \rightarrow 1} \frac{x \cdot \frac{1}{x} + \ln x}{1+x \cdot \frac{1}{x} + \ln x} = \boxed{\frac{1}{2}}.$$

81. Because

$$\lim_{x \rightarrow \pi/2^-} (x \tan x) = \infty \quad \text{and} \quad \lim_{x \rightarrow \pi/2^-} \frac{\pi}{2} \sec x = \infty,$$

while

$$\lim_{x \rightarrow \pi/2^+} (x \tan x) = -\infty \quad \text{and} \quad \lim_{x \rightarrow \pi/2^+} \frac{\pi}{2} \sec x = -\infty,$$

the expression $x \tan x - \frac{\pi}{2} \sec x$ is an indeterminate form at $\pi/2$ of the type $\infty - \infty$. Rewrite

$$x \tan x - \frac{\pi}{2} \sec x \quad \text{as} \quad x \frac{\sin x}{\cos x} - \frac{\pi}{2} \frac{1}{\cos x} = \frac{x \sin x - \frac{\pi}{2}}{\cos x},$$

which is an indeterminate form at $\pi/2$ of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\begin{aligned} \lim_{x \rightarrow \pi/2} \left(x \tan x - \frac{\pi}{2} \sec x \right) &= \lim_{x \rightarrow \pi/2} \frac{x \sin x - \frac{\pi}{2}}{\cos x} = \lim_{x \rightarrow \pi/2} \frac{\frac{d}{dx}(x \sin x - \frac{\pi}{2})}{\frac{d}{dx} \cos x} \\ &= \lim_{x \rightarrow \pi/2} \frac{x \cos x + \sin x}{-\sin x} = \frac{1}{-1} = \boxed{-1}. \end{aligned}$$

82. Because

$$\lim_{x \rightarrow \pi^-} \cot x = -\infty \quad \text{and} \quad \lim_{x \rightarrow \pi^-} (x \csc x) = \infty,$$

the expression $\cot x - x \csc x$ at π^- is of the form $-\infty - \infty$, which is not an indeterminate form; rather the value of this expression becomes unbounded in the negative direction. On the other hand,

$$\lim_{x \rightarrow \pi^+} \cot x = \infty \quad \text{and} \quad \lim_{x \rightarrow \pi^+} (x \csc x) = -\infty,$$

so the expression $\cot x - x \csc x$ at π^+ is of the form $\infty + \infty$, which is again not an indeterminate form; rather the value of this expression becomes unbounded in the positive direction. Therefore,

$$\lim_{x \rightarrow \pi} (\cot x - x \csc x)$$

does not exist.

83. Because

$$\lim_{x \rightarrow 1^-} (1 - x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 1^-} \tan(\pi x) = 0,$$

the expression $(1 - x)^{\tan(\pi x)}$ is an indeterminate form at 1^- of the type 0^0 . Let $y = (1 - x)^{\tan(\pi x)}$. Then

$$\ln y = \ln(1 - x)^{\tan(\pi x)} = \tan(\pi x) \ln(1 - x),$$

which is an indeterminate form at 1^- of the type $0 \cdot \infty$. Rewrite

$$\tan(\pi x) \ln(1 - x) \quad \text{as} \quad \frac{\ln(1 - x)}{\cot(\pi x)},$$

which is now an indeterminate form at 1^- of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\begin{aligned} \lim_{x \rightarrow 1^-} \ln y &= \lim_{x \rightarrow 1^-} [\tan(\pi x) \ln(1 - x)] = \lim_{x \rightarrow 1^-} \frac{\ln(1 - x)}{\cot(\pi x)} \\ &= \lim_{x \rightarrow 1^-} \frac{\frac{d}{dx} \ln(1 - x)}{\frac{d}{dx} \cot(\pi x)} = \lim_{x \rightarrow 1^-} \frac{\frac{-1}{1-x}}{-\pi \csc^2(\pi x)} = \lim_{x \rightarrow 1^-} \frac{\sin^2(\pi x)}{\pi(1 - x)}. \end{aligned}$$

Now,

$$\lim_{x \rightarrow 1^-} \sin^2(\pi x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 1^-} [\pi(1 - x)] = 0,$$

so the expression $\frac{\sin^2(\pi x)}{\pi(1 - x)}$ is an indeterminate form at 1^- of the type $\frac{0}{0}$. Using L'Hôpital's Rule again,

$$\lim_{x \rightarrow 1^-} \ln y = \lim_{x \rightarrow 1^-} \frac{\sin^2(\pi x)}{\pi(1 - x)} = \lim_{x \rightarrow 1^-} \frac{\frac{d}{dx} \sin^2(\pi x)}{\frac{d}{dx} [\pi(1 - x)]} = \lim_{x \rightarrow 1^-} \frac{2\pi \sin(\pi x) \cos(\pi x)}{-\pi} = 0.$$

Finally, because $\lim_{x \rightarrow 1^-} \ln y = 0$, it follows that

$$\lim_{x \rightarrow 1^-} y = \lim_{x \rightarrow 1^-} (1 - x)^{\tan(\pi x)} = e^0 = \boxed{1}.$$

84. Because

$$\lim_{x \rightarrow 0^+} x = 0 \quad \text{and} \quad \lim_{x \rightarrow 0^+} \sqrt{x} = 0,$$

the expression $x^{\sqrt{x}}$ is an indeterminate form at 0^+ of the type 0^0 . Let $y = x^{\sqrt{x}}$. Then

$$\ln y = \ln x^{\sqrt{x}} = \sqrt{x} \ln x,$$

which is an indeterminate form at 0^+ of the type $0 \cdot \infty$. Rewrite

$$\sqrt{x} \ln x \quad \text{as} \quad \frac{\ln x}{\frac{1}{\sqrt{x}}} = \frac{\ln x}{x^{-1/2}},$$

which is an indeterminate form at 0^+ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\begin{aligned} \lim_{x \rightarrow 0^+} \ln y &= \lim_{x \rightarrow 0^+} \sqrt{x} \ln x = \lim_{x \rightarrow 0^+} \frac{\ln x}{x^{-1/2}} \\ &= \lim_{x \rightarrow 0^+} \frac{\frac{d}{dx} \ln x}{\frac{d}{dx} x^{-1/2}} = \lim_{x \rightarrow 0^+} \frac{\frac{1}{x}}{-\frac{1}{2} x^{-3/2}} = \lim_{x \rightarrow 0^+} (-2\sqrt{x}) = 0. \end{aligned}$$

Finally, because $\lim_{x \rightarrow 0^+} \ln y = 0$, it follows that

$$\lim_{x \rightarrow 0^+} y = \lim_{x \rightarrow 0^+} x^{\sqrt{x}} = e^0 = \boxed{1}.$$

85. Because

$$\lim_{x \rightarrow 0^-} \frac{\sin x}{x} = 1 \quad \text{and} \quad \lim_{x \rightarrow 0^-} \frac{1}{x} = -\infty,$$

while

$$\lim_{x \rightarrow 0^+} \frac{\sin x}{x} = 1 \quad \text{and} \quad \lim_{x \rightarrow 0^+} \frac{1}{x} = \infty,$$

the expression $\left(\frac{\sin x}{x}\right)^{1/x}$ is an indeterminate form at 0 of the type 1^∞ . Let $y = \left(\frac{\sin x}{x}\right)^{1/x}$. Then

$$\ln y = \ln \left(\frac{\sin x}{x}\right)^{1/x} = \frac{1}{x} \ln \left(\frac{\sin x}{x}\right) = \frac{\ln \left(\frac{\sin x}{x}\right)}{x},$$

which is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 0} \ln y = \lim_{x \rightarrow 0} \frac{\ln \left(\frac{\sin x}{x}\right)}{x} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx} \ln \left(\frac{\sin x}{x}\right)}{\frac{d}{dx} x} = \lim_{x \rightarrow 0} \frac{\frac{x}{\sin x} \cdot \frac{x \cos x - \sin x}{x^2}}{1} = \lim_{x \rightarrow 0} \frac{x \cos x - \sin x}{x \sin x}.$$

Now,

$$\lim_{x \rightarrow 0} (x \cos x - \sin x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} (x \sin x) = 0,$$

so the expression $\frac{x \cos x - \sin x}{x \sin x}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule again,

$$\begin{aligned} \lim_{x \rightarrow 0} \ln y &= \lim_{x \rightarrow 0} \frac{x \cos x - \sin x}{x \sin x} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx} (x \cos x - \sin x)}{\frac{d}{dx} (x \sin x)} \\ &= \lim_{x \rightarrow 0} \frac{-x \sin x + \cos x - \cos x}{x \cos x + \sin x} = \lim_{x \rightarrow 0} \frac{-x \sin x}{x \cos x + \sin x}. \end{aligned}$$

Continuing,

$$\lim_{x \rightarrow 0} (-x \sin x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} (x \cos x + \sin x) = 0,$$

so the expression $\frac{-x \sin x}{x \cos x + \sin x}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule a third time,

$$\begin{aligned} \lim_{x \rightarrow 0} \ln y &= \lim_{x \rightarrow 0} \frac{-x \sin x}{x \cos x + \sin x} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx} (-x \sin x)}{\frac{d}{dx} (x \cos x + \sin x)} \\ &= \lim_{x \rightarrow 0} \frac{-x \cos x - \sin x}{-x \sin x + \cos x + \cos x} = 0. \end{aligned}$$

Finally, because $\lim_{x \rightarrow 0} \ln y = 0$, it follows that

$$\lim_{x \rightarrow 0} y = \lim_{x \rightarrow 0} \left(\frac{\sin x}{x} \right)^{1/x} = e^0 = \boxed{1}.$$

86. Because

$$\lim_{x \rightarrow \infty} \left(1 + \frac{5}{x} + \frac{3}{x^2} \right) = 1 \quad \text{and} \quad \lim_{x \rightarrow \infty} x = \infty,$$

the expression $\left(1 + \frac{5}{x} + \frac{3}{x^2} \right)^x$ is an indeterminate form at ∞ of the type 1^∞ . Let $y = \left(1 + \frac{5}{x} + \frac{3}{x^2} \right)^x$.

Then

$$\ln y = \ln \left(1 + \frac{5}{x} + \frac{3}{x^2} \right)^x = x \ln \left(1 + \frac{5}{x} + \frac{3}{x^2} \right),$$

which is an indeterminate form at ∞ of the type $0 \cdot \infty$. Rewrite

$$x \ln \left(1 + \frac{5}{x} + \frac{3}{x^2} \right) \quad \text{as} \quad \frac{\ln \left(1 + \frac{5}{x} + \frac{3}{x^2} \right)}{x^{-1}},$$

which is now an indeterminate form at ∞ of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\begin{aligned} \lim_{x \rightarrow \infty} \ln y &= \lim_{x \rightarrow \infty} \left[x \ln \left(1 + \frac{5}{x} + \frac{3}{x^2} \right) \right] = \lim_{x \rightarrow \infty} \frac{\ln \left(1 + \frac{5}{x} + \frac{3}{x^2} \right)}{x^{-1}} \\ &= \lim_{x \rightarrow \infty} \frac{\frac{d}{dx} \ln \left(1 + \frac{5}{x} + \frac{3}{x^2} \right)}{\frac{d}{dx} x^{-1}} = \lim_{x \rightarrow \infty} \frac{\frac{1}{1 + \frac{5}{x} + \frac{3}{x^2}} \cdot \left(-\frac{5}{x^2} - \frac{6}{x^3} \right)}{-x^{-2}} = \lim_{x \rightarrow \infty} \frac{5 + \frac{6}{x}}{1 + \frac{5}{x} + \frac{3}{x^2}} = \frac{5}{1} = 5. \end{aligned}$$

Finally, because $\lim_{x \rightarrow \infty} \ln y = 5$, it follows that

$$\lim_{x \rightarrow \infty} y = \lim_{x \rightarrow \infty} \left(1 + \frac{5}{x} + \frac{3}{x^2} \right)^x = \boxed{e^5}.$$

87. Because

$$\lim_{x \rightarrow \pi/2^-} \tan x = \infty \quad \text{and} \quad \lim_{x \rightarrow \pi/2^-} \cos x = 0,$$

the expression $(\tan x)^{\cos x}$ is an indeterminate form at $\pi/2^-$ of the type ∞^0 . Let $y = (\tan x)^{\cos x}$. Then

$$\ln y = \ln(\tan x)^{\cos x} = \cos x \ln(\tan x),$$

which is an indeterminate form at $\pi/2^-$ of the type $0 \cdot \infty$. Rewrite

$$\cos x \ln(\tan x) \quad \text{as} \quad \frac{\ln(\tan x)}{\sec x},$$

which is now an indeterminate form at $\pi/2^-$ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\begin{aligned} \lim_{x \rightarrow \pi/2^-} \ln y &= \lim_{x \rightarrow \pi/2^-} [\cos x \ln(\tan x)] = \lim_{x \rightarrow \pi/2^-} \frac{\ln(\tan x)}{\sec x} \\ &= \lim_{x \rightarrow \pi/2^-} \frac{\frac{d}{dx} \ln(\tan x)}{\frac{d}{dx} \sec x} = \lim_{x \rightarrow \pi/2^-} \frac{\cot x \cdot \sec^2 x}{\sec x \tan x} = \lim_{x \rightarrow \pi/2^-} \frac{\cos x}{\sin^2 x} = 0. \end{aligned}$$

Finally, because $\lim_{x \rightarrow \pi/2^-} \ln y = 0$, it follows that

$$\lim_{x \rightarrow \pi/2^-} y = \lim_{x \rightarrow \pi/2^-} (\tan x)^{\cos x} = e^0 = \boxed{1}.$$

88. Because

$$\lim_{x \rightarrow 0^+} (x^2 + x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0^+} (-\ln x) = \infty,$$

the expression $(x^2 + x)^{-\ln x}$ is of the form 0^∞ , which is not an indeterminate form; rather the value of this expression tends toward 0. Therefore,

$$\lim_{x \rightarrow 0^+} (x^2 + x)^{-\ln x} = \boxed{0}.$$

89. Because

$$\lim_{x \rightarrow 0} \cosh x = 1 \quad \text{and} \quad \lim_{x \rightarrow 0} e^x = 1,$$

the expression $(\cosh x)^{e^x}$ is of the form 1^1 , which is not an indeterminate form; rather the value of this expression tends toward 1. Therefore,

$$\lim_{x \rightarrow 0} (\cosh x)^{e^x} = \boxed{1}.$$

90. Because

$$\lim_{x \rightarrow 0^+} \sinh x = 0 \quad \text{and} \quad \lim_{x \rightarrow 0^+} x = 0,$$

the expression $(\sinh x)^x$ is an indeterminate form at 0^+ of the type 0^0 . Let $y = (\sinh x)^x$. Then

$$\ln y = \ln(\sinh x)^x = x \ln(\sinh x),$$

which is an indeterminate form at 0^+ of the type $0 \cdot \infty$. Rewrite

$$x \ln(\sinh x) \quad \text{as} \quad \frac{\ln(\sinh x)}{x^{-1}},$$

which is now an indeterminate form at 0^+ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\begin{aligned} \lim_{x \rightarrow 0^+} \ln y &= \lim_{x \rightarrow 0^+} x \ln(\sinh x) = \lim_{x \rightarrow 0^+} \frac{\ln(\sinh x)}{x^{-1}} \\ &= \lim_{x \rightarrow 0^+} \frac{\frac{d}{dx} \ln(\sinh x)}{\frac{d}{dx} x^{-1}} = \lim_{x \rightarrow 0^+} \frac{\frac{1}{\sinh x} \cdot \cosh x}{-x^{-2}} = \lim_{x \rightarrow 0^+} \frac{-x^2 \cosh x}{\sinh x}. \end{aligned}$$

Now,

$$\lim_{x \rightarrow 0^+} (-x^2 \cosh x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0^+} \sinh x = 0,$$

so the expression $\frac{-x^2 \cosh x}{\sinh x}$ is an indeterminate form at 0^+ of the type $\frac{0}{0}$. Using L'Hôpital's Rule again,

$$\lim_{x \rightarrow 0^+} \ln y = \lim_{x \rightarrow 0^+} \frac{-x^2 \cosh x}{\sinh x} = \lim_{x \rightarrow 0^+} \frac{\frac{d}{dx}(-x^2 \cosh x)}{\frac{d}{dx} \sinh x} = \lim_{x \rightarrow 0^+} \frac{-x^2 \sinh x - 2x \cosh x}{\cosh x} = 0.$$

Finally, because $\lim_{x \rightarrow 0^+} \ln y = 0$, it follows that

$$\lim_{x \rightarrow 0^+} y = \lim_{x \rightarrow 0^+} (\sinh x)^x = e^0 = \boxed{1}.$$

Applications and Extensions

91. Let

$$w(t) = \frac{K e^{rt}}{\frac{K}{40} + e^{rt} - 1},$$

where $K = 366$, $r = 0.283$, and $t = 0$ represents the year 2000.

(a) Because $r > 0$,

$$\lim_{t \rightarrow \infty} Ke^{rt} = \infty, \quad \text{and} \quad \lim_{t \rightarrow \infty} \left(\frac{K}{40} + e^{rt} - 1 \right) = \infty,$$

$w(t)$ is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\lim_{t \rightarrow \infty} w(t) = \lim_{t \rightarrow \infty} \frac{Ke^{rt}}{\frac{K}{40} + e^{rt} - 1} = \lim_{t \rightarrow \infty} \frac{\frac{d}{dt} Ke^{rt}}{\frac{d}{dt} \left(\frac{K}{40} + e^{rt} - 1 \right)} = \lim_{t \rightarrow \infty} \frac{Kre^{rt}}{re^{rt}} = \lim_{t \rightarrow \infty} K = \boxed{K = 366}.$$

(b) If the population of wolves in Wyoming outside of Yellowstone National Park continues to follow the given logistic curve, in the long run, the population will reach $K = 366$ wolves.

(c) The figure below displays the graph of the wolf population.

92. Let

$$v(t) = -A + RA \frac{e^{Bt+C} - 1}{e^{Bt+C} + 1},$$

where t is the time measured in seconds, and A , B , C , and R are positive constants with $R > 1$.

(a) Because B is positive

$$\lim_{t \rightarrow \infty} (e^{Bt+C} - 1) = \infty, \quad \text{and} \quad \lim_{t \rightarrow \infty} (e^{Bt+C} + 1) = \infty,$$

the expression $\frac{e^{Bt+C} - 1}{e^{Bt+C} + 1}$ is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\lim_{t \rightarrow \infty} \frac{e^{Bt+C} - 1}{e^{Bt+C} + 1} = \lim_{t \rightarrow \infty} \frac{\frac{d}{dt}(e^{Bt+C} - 1)}{\frac{d}{dt}(e^{Bt+C} + 1)} = \lim_{t \rightarrow \infty} \frac{Be^{Bt+C}}{Be^{Bt+C}} = \lim_{t \rightarrow \infty} 1 = 1.$$

Therefore,

$$\lim_{t \rightarrow \infty} v(t) = \lim_{t \rightarrow \infty} \left(-A + RA \frac{e^{Bt+C} - 1}{e^{Bt+C} + 1} \right) = -A + RA \cdot 1 = \boxed{(R-1)A}.$$

(b) In the long run, the skydiver's downward velocity approaches $(R-1)A$, known as the terminal velocity.

(c) The figure below displays the graph of the skydiver's speed in feet per second, with $A = 108.6$, $B = 0.554$, $C = 0.804$, and $R = 2.62$.

93. (a) Let

$$I = \frac{E}{R}(1 - e^{-Rt/L}).$$

First,

$$\lim_{t \rightarrow \infty} I(t) = \lim_{t \rightarrow \infty} \frac{E}{R}(1 - e^{-Rt/L}) = \frac{E}{R} \cdot 1 = \boxed{\frac{E}{R}}.$$

Next, for the limit as $R \rightarrow 0^+$, note that

$$\lim_{R \rightarrow 0^+} E(1 - e^{-Rt/L}) = 0 \quad \text{and} \quad \lim_{R \rightarrow 0^+} R = 0,$$

so $I(t)$ is an indeterminate form at $R = 0^+$ of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{R \rightarrow 0^+} I(t) = \lim_{R \rightarrow 0^+} \frac{E(1 - e^{-Rt/L})}{R} = \lim_{R \rightarrow 0^+} \frac{\frac{d}{dR}[E(1 - e^{-Rt/L})]}{\frac{d}{dR}R} = \lim_{R \rightarrow 0^+} \frac{E \frac{t}{L} e^{-Rt/L}}{1} = \boxed{\frac{Et}{L}}.$$

(b) After the circuit has been active for a long time, the current will level out at the value E/R . On the other hand, in the limit as the resistance goes to zero, the current becomes a linear function of time, $I(t) = Et/L$.

94. Because

$$\lim_{x \rightarrow 0} (a^x - b^x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} x = 0,$$

the expression $\frac{a^x - b^x}{x}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 0} \frac{a^x - b^x}{x} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx}(a^x - b^x)}{\frac{d}{dx}x} = \lim_{x \rightarrow 0} (a^x \ln a - b^x \ln b) = \boxed{\ln a - \ln b}.$$

95. Let $n \geq 1$ be an integer. Because

$$\lim_{x \rightarrow \infty} \ln x = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} x^n = \infty,$$

the expression $\frac{\ln x}{x^n}$ is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's rule,

$$\lim_{x \rightarrow \infty} \frac{\ln x}{x^n} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx} \ln x}{\frac{d}{dx} x^n} = \lim_{x \rightarrow \infty} \frac{\frac{1}{x}}{nx^{n-1}} = \lim_{x \rightarrow \infty} \frac{1}{nx^n} = 0,$$

because $n \geq 1$.

96. Let $n \geq 1$ be an integer. Because

$$\lim_{x \rightarrow \infty} e^x = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} x^n = \infty,$$

the expression $\frac{x^n}{e^x}$ is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's rule,

$$\lim_{x \rightarrow \infty} \frac{x^n}{e^x} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx} x^n}{\frac{d}{dx} e^x} = n \lim_{x \rightarrow \infty} \frac{x^{n-1}}{e^x}.$$

Continuing to use L'Hôpital's Rule yields,

$$\begin{aligned} \lim_{x \rightarrow \infty} \frac{x^n}{e^x} &= n \lim_{x \rightarrow \infty} \frac{x^{n-1}}{e^x} \\ &= n(n-1) \lim_{x \rightarrow \infty} \frac{x^{n-2}}{e^x} \\ &= n(n-1)(n-2) \lim_{x \rightarrow \infty} \frac{x^{n-3}}{e^x} \\ &\vdots \\ &= n(n-1)(n-2) \cdots 2 \lim_{x \rightarrow \infty} \frac{x}{e^x} \\ &= n(n-1)(n-2) \cdots 2 \cdot 1 \lim_{x \rightarrow \infty} \frac{1}{e^x} = 0. \end{aligned}$$

Therefore,

$$\lim_{x \rightarrow \infty} \frac{x^n}{e^x} = 0.$$

97. Because

$$\lim_{x \rightarrow 0^+} (\cos x + 2 \sin x) = 1 \quad \text{and} \quad \lim_{x \rightarrow 0^+} \cot x = \infty,$$

the expression $(\cos x + 2 \sin x)^{\cot x}$ is an indeterminate form at 0^+ of the type 1^∞ . Let $y = (\cos x + 2 \sin x)^{\cot x}$. Then

$$\ln y = \ln(\cos x + 2 \sin x)^{\cot x} = \cot x \ln(\cos x + 2 \sin x),$$

which is an indeterminate form at 0^+ of the type $0 \cdot \infty$. Rewrite

$$\cot x \ln(\cos x + 2 \sin x) \quad \text{as} \quad \frac{\ln(\cos x + 2 \sin x)}{\tan x},$$

which is now an indeterminate form at 0^+ of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\begin{aligned} \lim_{x \rightarrow 0^+} \ln y &= \lim_{x \rightarrow 0^+} [\cot x \ln(\cos x + 2 \sin x)] = \lim_{x \rightarrow 0^+} \frac{\ln(\cos x + 2 \sin x)}{\tan x} \\ &= \lim_{x \rightarrow 0^+} \frac{\frac{d}{dx} \ln(\cos x + 2 \sin x)}{\frac{d}{dx} \tan x} = \lim_{x \rightarrow 0^+} \frac{\frac{1}{\cos x + 2 \sin x} \cdot (-\sin x + 2 \cos x)}{\sec^2 x} = \frac{1(2)}{1} = 2. \end{aligned}$$

Finally, because $\lim_{x \rightarrow 0^+} \ln y = 2$, it follows that

$$\lim_{x \rightarrow 0^+} y = \lim_{x \rightarrow 0^+} (\cos x + 2 \sin x)^{\cot x} = e^2.$$

98. Let P be a polynomial function of degree n with leading coefficient $a_n \neq 0$. Because

$$\lim_{x \rightarrow \infty} e^x = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} P^{(k)}(x) = \pm \infty$$

for $k < n$, the expression $\frac{P^{(k)}(x)}{e^x}$ is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$ for $k < n$. Applying L'Hôpital's Rule n times then yields

$$\begin{aligned}\lim_{x \rightarrow \infty} \frac{P(x)}{e^x} &= \lim_{x \rightarrow \infty} \frac{\frac{d}{dx}P(x)}{\frac{d}{dx}e^x} = \lim_{x \rightarrow \infty} \frac{P'(x)}{e^x} \\ &= \lim_{x \rightarrow \infty} \frac{P''(x)}{e^x} \\ &\vdots \\ &= \lim_{x \rightarrow \infty} \frac{P^{(n)}(x)}{e^x} = \boxed{0},\end{aligned}$$

because

$$\lim_{x \rightarrow \infty} P^{(n)}(x) = n!a_n < \infty.$$

99. Using the properties of the natural logarithm function,

$$\ln(x+1) - \ln(x-1) = \ln \frac{x+1}{x-1},$$

so

$$\lim_{x \rightarrow \infty} [\ln(x+1) - \ln(x-1)] = \lim_{x \rightarrow \infty} \ln \frac{x+1}{x-1} = \ln \left(\lim_{x \rightarrow \infty} \frac{x+1}{x-1} \right).$$

Now,

$$\lim_{x \rightarrow \infty} (x+1) = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} (x-1) = \infty,$$

so the expression $\frac{x+1}{x-1}$ is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow \infty} \frac{x+1}{x-1} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx}(x+1)}{\frac{d}{dx}(x-1)} = \lim_{x \rightarrow \infty} \frac{1}{1} = 1.$$

Therefore,

$$\lim_{x \rightarrow \infty} [\ln(x+1) - \ln(x-1)] = \ln \left(\lim_{x \rightarrow \infty} \frac{x+1}{x-1} \right) = \ln 1 = \boxed{0}.$$

100. Because

$$\lim_{x \rightarrow 0^+} e^{-1/x^2} = 0 \quad \text{and} \quad \lim_{x \rightarrow 0^+} x = 0,$$

the expression $\frac{e^{-1/x^2}}{x}$ is an indeterminate form at 0^+ of the type $\frac{0}{0}$. Following the hint in the problem statement, rewrite

$$\frac{e^{-1/x^2}}{x} \quad \text{as} \quad \frac{\frac{1}{x}}{e^{1/x^2}},$$

which is an indeterminate form at 0^+ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\begin{aligned}\lim_{x \rightarrow 0^+} \frac{e^{-1/x^2}}{x} &= \lim_{x \rightarrow 0^+} \frac{x^{-1}}{e^{1/x^2}} = \lim_{x \rightarrow 0^+} \frac{\frac{d}{dx}x^{-1}}{\frac{d}{dx}e^{1/x^2}} \\ &= \lim_{x \rightarrow 0^+} \frac{-x^{-2}}{e^{1/x^2} \cdot -2x^{-3}} = \lim_{x \rightarrow 0^+} \frac{x}{2e^{1/x^2}} = \lim_{x \rightarrow 0^+} \frac{xe^{-1/x^2}}{2} = 0.\end{aligned}$$

101. Let n be an integer. If $n < 0$, then $-n > 0$, $\lim_{x \rightarrow 0^+} x^{-n} = 0$, and

$$\lim_{x \rightarrow 0^+} \frac{e^{-1/x^2}}{x^n} = \lim_{x \rightarrow 0^+} (x^{-n} e^{-1/x^2}) = 0.$$

If $n = 0$, then

$$\lim_{x \rightarrow 0^+} \frac{e^{-1/x^2}}{x^n} = \lim_{x \rightarrow 0^+} e^{-1/x^2} = 0.$$

Finally, suppose $n > 0$. Further suppose that k is the smallest positive integer such that $-n + 2k \geq 0$. Because

$$\lim_{x \rightarrow 0^+} e^{1/x^2} = \infty \quad \text{and} \quad \lim_{x \rightarrow 0^+} x^{-c} = \infty$$

for $c > 0$, the expression $\frac{x^{-c}}{e^{1/x^2}} = \frac{e^{-1/x^2}}{x^c}$ is an indeterminate form at 0^+ of the type $\frac{\infty}{\infty}$ for all $c > 0$. Using L'Hôpital's Rule k times yields

$$\begin{aligned} \lim_{x \rightarrow 0^+} \frac{e^{-1/x^2}}{x^n} &= \lim_{x \rightarrow 0^+} \frac{x^{-n}}{e^{1/x^2}} = \lim_{x \rightarrow 0^+} \frac{-nx^{-n-1}}{e^{1/x^2} \cdot -\frac{2}{x^3}} = \frac{n}{2} \lim_{x \rightarrow 0^+} \frac{x^{-n+2}}{e^{1/x^2}} \\ &= \frac{n(n-2)}{2^2} \lim_{x \rightarrow 0^+} \frac{x^{-n+4}}{e^{1/x^2}} \\ &\vdots \\ &= \frac{n(n-2) \cdots (n-2k+2)}{2^k} \lim_{x \rightarrow 0^+} \frac{x^{-n+2k}}{e^{1/x^2}}. \end{aligned}$$

If $-n + 2k = 0$, then

$$\lim_{x \rightarrow 0^+} \frac{x^{-n+2k}}{e^{1/x^2}} = \lim_{x \rightarrow 0^+} \frac{1}{e^{1/x^2}} = 0;$$

otherwise,

$$\lim_{x \rightarrow 0^+} \frac{x^{-n+2k}}{e^{1/x^2}} = \lim_{x \rightarrow 0^+} \frac{1}{x^{n-2k} e^{1/x^2}} = 0.$$

Therefore,

$$\lim_{x \rightarrow 0^+} \frac{e^{-1/x^2}}{x^n} = 0.$$

102. Because

$$\lim_{x \rightarrow \infty} x = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} \frac{1}{x} = 0,$$

the expression $\sqrt[x]{x} = x^{1/x}$ is an indeterminate form at ∞ of the type ∞^0 . Let $y = x^{1/x}$. Then

$$\ln y = \ln x^{1/x} = \frac{1}{x} \ln x = \frac{\ln x}{x},$$

which is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow \infty} \ln y = \lim_{x \rightarrow \infty} \frac{\ln x}{x} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx} \ln x}{\frac{d}{dx} x} = \lim_{x \rightarrow \infty} \frac{\frac{1}{x}}{1} = \lim_{x \rightarrow \infty} \frac{1}{x} = 0.$$

Finally, because $\lim_{x \rightarrow \infty} \ln y = 0$, it follows that

$$\lim_{x \rightarrow \infty} y = \lim_{x \rightarrow \infty} \sqrt[x]{x} = e^0 = 1.$$

103. Because

$$\lim_{x \rightarrow \infty} \left(1 + \frac{a}{x}\right) = 1 \quad \text{and} \quad \lim_{x \rightarrow \infty} x = \infty,$$

the expression $\left(1 + \frac{a}{x}\right)^x$ is an indeterminate form at ∞ of the type 1^∞ . Let $y = \left(1 + \frac{a}{x}\right)^x$. Then

$$\ln y = \ln \left(1 + \frac{a}{x}\right)^x = x \ln \left(1 + \frac{a}{x}\right),$$

which is an indeterminate form at ∞ of the type $0 \cdot \infty$. Rewrite

$$x \ln \left(1 + \frac{a}{x}\right) \quad \text{as} \quad \frac{\ln \left(1 + \frac{a}{x}\right)}{\frac{1}{x}},$$

which is now an indeterminate form at ∞ of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\begin{aligned} \lim_{x \rightarrow \infty} \ln y &= \lim_{x \rightarrow \infty} \left[x \ln \left(1 + \frac{a}{x}\right) \right] = \lim_{x \rightarrow \infty} \frac{\ln \left(1 + \frac{a}{x}\right)}{\frac{1}{x}} \\ &= \lim_{x \rightarrow \infty} \frac{\frac{d}{dx} \ln \left(1 + \frac{a}{x}\right)}{\frac{d}{dx} \frac{1}{x}} = \lim_{x \rightarrow \infty} \frac{\frac{1}{1 + \frac{a}{x}} \cdot -\frac{a}{x^2}}{-\frac{1}{x^2}} = \lim_{x \rightarrow \infty} \frac{a}{1 + \frac{a}{x}} = \frac{a}{1} = a. \end{aligned}$$

Finally, because $\lim_{x \rightarrow \infty} \ln y = a$, it follows that

$$\lim_{x \rightarrow \infty} y = \lim_{x \rightarrow \infty} \left(1 + \frac{a}{x}\right)^x = e^a.$$

104. Because

$$\lim_{x \rightarrow \infty} \frac{x+a}{x-a} = \lim_{x \rightarrow \infty} \frac{x+a}{x-a} \cdot \frac{\frac{1}{x}}{\frac{1}{x}} = \lim_{x \rightarrow \infty} \frac{1 + \frac{a}{x}}{1 - \frac{a}{x}} = 1 \quad \text{and} \quad \lim_{x \rightarrow \infty} x = \infty,$$

the expression $\left(\frac{x+a}{x-a}\right)^x$ is an indeterminate form at ∞ of the type 1^∞ . Let $y = \left(\frac{x+a}{x-a}\right)^x$. Then

$$\ln y = \ln \left(\frac{x+a}{x-a}\right)^x = x \ln \left(\frac{x+a}{x-a}\right),$$

which is an indeterminate form at ∞ of the type $0 \cdot \infty$. Rewrite

$$x \ln \left(\frac{x+a}{x-a}\right) \quad \text{as} \quad \frac{\ln \left(\frac{x+a}{x-a}\right)}{\frac{1}{x}},$$

which is now an indeterminate form at ∞ of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\begin{aligned} \lim_{x \rightarrow \infty} \ln y &= \lim_{x \rightarrow \infty} \left[x \ln \left(\frac{x+a}{x-a}\right) \right] = \lim_{x \rightarrow \infty} \frac{\ln \left(\frac{x+a}{x-a}\right)}{\frac{1}{x}} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx} \ln \left(\frac{x+a}{x-a}\right)}{\frac{d}{dx} \frac{1}{x}} \\ &= \lim_{x \rightarrow \infty} \frac{\frac{x-a}{x+a} \cdot \frac{(x-a)(1) - (x+a)(1)}{(x-a)^2}}{-\frac{1}{x^2}} = \lim_{x \rightarrow \infty} \frac{2ax^2}{(x-a)(x+a)} \cdot \frac{\frac{1}{x^2}}{\frac{1}{x^2}} \\ &= \lim_{x \rightarrow \infty} \frac{2a}{\left(1 - \frac{a}{x}\right)\left(1 + \frac{a}{x}\right)} = \frac{2a}{1(1)} = 2a. \end{aligned}$$

Finally, because $\lim_{x \rightarrow \infty} \ln y = 2a$, it follows that

$$\lim_{x \rightarrow \infty} y = \lim_{x \rightarrow \infty} \left(\frac{x+a}{x-a}\right)^x = e^{2a}.$$

105. (a) Note that

$$\lim_{x \rightarrow 0} \frac{f(x) - f(0)}{x - 0} = \lim_{x \rightarrow 0} \frac{e^{-1/x^2} - 0}{x} = \lim_{x \rightarrow 0} \frac{e^{-1/x^2}}{x} = 0$$

by Problem 100. Because this limit exists, it follows that f is differentiable at 0; moreover, $f'(0) = 0$.

(b) The figure below displays the graph of f .

106. Let a , $b \neq 0$, and $c > 0$ be real numbers. Because

$$\lim_{x \rightarrow c} (x^a - c^a) = 0 \quad \text{and} \quad \lim_{x \rightarrow c} (x^b - c^b) = 0,$$

the expression $\frac{x^a - c^a}{x^b - c^b}$ is an indeterminate form at c of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow c} \frac{x^a - c^a}{x^b - c^b} = \lim_{x \rightarrow c} \frac{\frac{d}{dx}(x^a - c^a)}{\frac{d}{dx}(x^b - c^b)} = \lim_{x \rightarrow c} \frac{ax^{a-1}}{bx^{b-1}} = \frac{ac^{a-1}}{bc^{b-1}} = \frac{a}{b}c^{a-b}.$$

107. Suppose the expression $\frac{f(x)}{g(x)}$ is an indeterminate form at $-\infty$ of the type $\frac{0}{0}$. Then

$$\lim_{x \rightarrow -\infty} f(x) = 0 \quad \text{and} \quad \lim_{x \rightarrow -\infty} g(x) = 0.$$

Define

$$F(t) = f\left(\frac{1}{t}\right) \quad \text{and} \quad G(t) = g\left(\frac{1}{t}\right).$$

Now, consider the limit

$$\lim_{x \rightarrow -\infty} \frac{f(x)}{g(x)}.$$

Make the substitution $t = 1/x$. Then, as $x \rightarrow -\infty$, $t \rightarrow 0^-$, and

$$\lim_{x \rightarrow -\infty} \frac{f(x)}{g(x)} = \lim_{t \rightarrow 0^-} \frac{f\left(\frac{1}{t}\right)}{g\left(\frac{1}{t}\right)} = \lim_{t \rightarrow 0^-} \frac{F(t)}{G(t)}.$$

Because

$$\lim_{t \rightarrow 0^-} F(t) = \lim_{t \rightarrow 0^-} f\left(\frac{1}{t}\right) = \lim_{x \rightarrow -\infty} f(x) = 0$$

and

$$\lim_{t \rightarrow 0^-} G(t) = \lim_{t \rightarrow 0^-} g\left(\frac{1}{t}\right) = \lim_{x \rightarrow -\infty} g(x) = 0,$$

the expression $\frac{F(t)}{G(t)}$ is an indeterminate form at 0^- of the type $\frac{0}{0}$. By the partial proof of L'Hôpital's Rule provided in the text, it follows that

$$\lim_{t \rightarrow 0^-} \frac{F(t)}{G(t)} = \lim_{t \rightarrow 0^-} \frac{F'(t)}{G'(t)}.$$

By the definition of F and G

$$F'(t) = -\frac{1}{t^2} f' \left(\frac{1}{t} \right) \quad \text{and} \quad G'(t) = -\frac{1}{t^2} g' \left(\frac{1}{t} \right),$$

so

$$\lim_{x \rightarrow -\infty} \frac{f(x)}{g(x)} = \lim_{t \rightarrow 0^-} \frac{F(t)}{G(t)} = \lim_{t \rightarrow 0^-} \frac{F'(t)}{G'(t)} = \lim_{t \rightarrow 0^-} \frac{-\frac{1}{t^2} f' \left(\frac{1}{t} \right)}{-\frac{1}{t^2} g' \left(\frac{1}{t} \right)} = \lim_{t \rightarrow 0^-} \frac{f' \left(\frac{1}{t} \right)}{g' \left(\frac{1}{t} \right)} = \lim_{x \rightarrow -\infty} \frac{f'(x)}{g'(x)},$$

as desired.

Challenge Problems

108. L'Hôpital's Rule states that, if the expression $\frac{f(x)}{g(x)}$ is an indeterminate form at c of the type $\frac{0}{0}$ or $\frac{\infty}{\infty}$, then

$$\lim_{x \rightarrow c} \frac{f(x)}{g(x)} = \lim_{x \rightarrow c} \frac{f'(x)}{g'(x)},$$

provided the limit on the right-hand side exists. Now, it can be shown that

$$\lim_{x \rightarrow 0} \left(x^2 \sin \frac{1}{x} \right) = 0$$

by the Squeeze Theorem, and $\lim_{x \rightarrow 0} \sin x = 0$, so the expression $\frac{x^2 \sin \frac{1}{x}}{\sin x}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Moreover,

$$\frac{d}{dx} \left(x^2 \sin \frac{1}{x} \right) = -\cos \frac{1}{x} + 2x \sin \frac{1}{x},$$

so

$$\lim_{x \rightarrow 0} \frac{\frac{d}{dx} \left(x^2 \sin \frac{1}{x} \right)}{\frac{d}{dx} \sin x} = \lim_{x \rightarrow 0} \frac{-\cos \frac{1}{x} + 2x \sin \frac{1}{x}}{\cos x}.$$

Although $\lim_{x \rightarrow 0} \left(2x \sin \frac{1}{x} \right) = 0$ by the Squeeze Theorem and $\lim_{x \rightarrow 0} \cos x = 1$,

$$\lim_{x \rightarrow 0} \cos \frac{1}{x}$$

does not exist because the cosine function does not approach a single number. Therefore,

$$\lim_{x \rightarrow 0} \frac{\frac{d}{dx} \left(x^2 \sin \frac{1}{x} \right)}{\frac{d}{dx} \sin x}$$

does not exist, so L'Hôpital's Rule does not apply to

$$\lim_{x \rightarrow 0} \frac{x^2 \sin \frac{1}{x}}{\sin x}.$$

109. (a) Because

$$\lim_{x \rightarrow \infty} \left(1 + \frac{1}{x}\right) = 1 \quad \text{and} \quad \lim_{x \rightarrow \infty} (-x^2) = -\infty,$$

the expression $\left(1 + \frac{1}{x}\right)^{-x^2}$ is an indeterminate form at ∞ of the type 1^∞ . Let $y = \left(1 + \frac{1}{x}\right)^{-x^2}$. Then

$$\ln y = \ln \left(1 + \frac{1}{x}\right)^{-x^2} = -x^2 \ln \left(1 + \frac{1}{x}\right),$$

which is an indeterminate form at ∞ of the type $0 \cdot \infty$. Rewrite

$$-x^2 \ln \left(1 + \frac{1}{x}\right) \quad \text{as} \quad \frac{\ln \left(1 + \frac{1}{x}\right)}{-\frac{1}{x^2}},$$

which is now an indeterminate form at ∞ of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\begin{aligned} \lim_{x \rightarrow \infty} \ln y &= \lim_{x \rightarrow \infty} \left[-x^2 \ln \left(1 + \frac{1}{x}\right) \right] = \lim_{x \rightarrow \infty} \frac{\ln \left(1 + \frac{1}{x}\right)}{-\frac{1}{x^2}} \\ &= \lim_{x \rightarrow \infty} \frac{\frac{d}{dx} \ln \left(1 + \frac{1}{x}\right)}{\frac{d}{dx} \left(-\frac{1}{x^2}\right)} = \lim_{x \rightarrow \infty} \frac{\frac{1}{1+\frac{1}{x}} \cdot -\frac{1}{x^2}}{\frac{2}{x^3}} = \lim_{x \rightarrow \infty} \frac{-x}{2 \left(1 + \frac{1}{x}\right)} = -\infty. \end{aligned}$$

Finally, because $\lim_{x \rightarrow \infty} \ln y = -\infty$, it follows that

$$\lim_{x \rightarrow \infty} y = \lim_{x \rightarrow \infty} \left(1 + \frac{1}{x}\right)^{-x^2} = \lim_{x \rightarrow \infty} e^{\ln y} = \boxed{0}.$$

(b) Because

$$\lim_{x \rightarrow \infty} \left(1 + \frac{\ln a}{x}\right) = 1 \quad \text{and} \quad \lim_{x \rightarrow \infty} x = \infty,$$

the expression $\left(1 + \frac{\ln a}{x}\right)^x$ is an indeterminate form at ∞ of the type 1^∞ . Let $y = \left(1 + \frac{\ln a}{x}\right)^x$. Then

$$\ln y = \ln \left(1 + \frac{\ln a}{x}\right)^x = x \ln \left(1 + \frac{\ln a}{x}\right),$$

which is an indeterminate form at ∞ of the type $0 \cdot \infty$. Rewrite

$$x \ln \left(1 + \frac{\ln a}{x}\right) \quad \text{as} \quad \frac{\ln \left(1 + \frac{\ln a}{x}\right)}{\frac{1}{x}},$$

which is now an indeterminate form at ∞ of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\begin{aligned} \lim_{x \rightarrow \infty} \ln y &= \lim_{x \rightarrow \infty} \left[x \ln \left(1 + \frac{\ln a}{x}\right) \right] = \lim_{x \rightarrow \infty} \frac{\ln \left(1 + \frac{\ln a}{x}\right)}{\frac{1}{x}} \\ &= \lim_{x \rightarrow \infty} \frac{\frac{d}{dx} \ln \left(1 + \frac{\ln a}{x}\right)}{\frac{d}{dx} \left(\frac{1}{x}\right)} = \lim_{x \rightarrow \infty} \frac{\frac{1}{1+\frac{\ln a}{x}} \cdot -\frac{\ln a}{x^2}}{-\frac{1}{x^2}} = \lim_{x \rightarrow \infty} \frac{\ln a}{1 + \frac{\ln a}{x}} = \ln a. \end{aligned}$$

Finally, because $\lim_{x \rightarrow \infty} \ln y = \ln a$, it follows that

$$\lim_{x \rightarrow \infty} y = \lim_{x \rightarrow \infty} \left(1 + \frac{\ln a}{x}\right)^x = e^{\ln a} = \boxed{a}.$$

(c) Because

$$\lim_{x \rightarrow \infty} \left(1 + \frac{1}{x}\right) = 1 \quad \text{and} \quad \lim_{x \rightarrow \infty} x^2 = \infty,$$

the expression $\left(1 + \frac{1}{x}\right)^{x^2}$ is an indeterminate form at ∞ of the type 1^∞ . Let $y = \left(1 + \frac{1}{x}\right)^{x^2}$. Then

$$\ln y = \ln \left(1 + \frac{1}{x}\right)^{x^2} = x^2 \ln \left(1 + \frac{1}{x}\right),$$

which is an indeterminate form at ∞ of the type $0 \cdot \infty$. Rewrite

$$x^2 \ln \left(1 + \frac{1}{x}\right) \quad \text{as} \quad \frac{\ln \left(1 + \frac{1}{x}\right)}{\frac{1}{x^2}},$$

which is now an indeterminate form at ∞ of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\begin{aligned} \lim_{x \rightarrow \infty} \ln y &= \lim_{x \rightarrow \infty} \left[x^2 \ln \left(1 + \frac{1}{x}\right) \right] = \lim_{x \rightarrow \infty} \frac{\ln \left(1 + \frac{1}{x}\right)}{\frac{1}{x^2}} \\ &= \lim_{x \rightarrow \infty} \frac{\frac{d}{dx} \ln \left(1 + \frac{1}{x}\right)}{\frac{d}{dx} \left(\frac{1}{x^2}\right)} = \lim_{x \rightarrow \infty} \frac{\frac{1}{1+\frac{1}{x}} \cdot -\frac{1}{x^2}}{-\frac{2}{x^3}} = \lim_{x \rightarrow \infty} \frac{x}{2 \left(1 + \frac{1}{x}\right)} = \infty. \end{aligned}$$

Finally, because $\lim_{x \rightarrow \infty} \ln y = \infty$, it follows that

$$\lim_{x \rightarrow \infty} y = \lim_{x \rightarrow \infty} \left(1 + \frac{1}{x}\right)^{x^2} = \lim_{x \rightarrow \infty} e^{\ln y} = \boxed{\infty}.$$

(d) This limit does not exist. To show this, first let $x = n\pi$, where n is a natural number. As $n \rightarrow \infty$, $x \rightarrow \infty$, and

$$\left(1 + \frac{\sin x}{x}\right)^x = \left(1 + \frac{\sin(n\pi)}{n\pi}\right)^{n\pi} = 1^{n\pi} = 1.$$

Next, let $x = \frac{\pi}{2} + 2n\pi$, where n is a natural number. Again, as $n \rightarrow \infty$, $x \rightarrow \infty$, but

$$\left(1 + \frac{\sin x}{x}\right)^x = \left(1 + \frac{\sin(\pi/2 + 2n\pi)}{\pi/2 + 2n\pi}\right)^{\pi/2 + 2n\pi} = \left(1 + \frac{1}{\pi/2 + 2n\pi}\right)^{\pi/2 + 2n\pi} \rightarrow e.$$

Because the value of

$$\left(1 + \frac{\sin x}{x}\right)^x$$

does not approach a single number as $x \rightarrow \infty$, the indicated limit does not exist.

(e) Because

$$\lim_{x \rightarrow \infty} e^x = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} -\frac{1}{\ln x} = 0,$$

the expression $(e^x)^{-1/\ln x}$ is an indeterminate form at ∞ of the type ∞^0 . Let $y = (e^x)^{-1/\ln x}$. Then

$$\ln y = \ln(e^x)^{-1/\ln x} = -\frac{1}{\ln x} \ln e^x = -\frac{x}{\ln x},$$

which is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow \infty} \ln y = \lim_{x \rightarrow \infty} -\frac{x}{\ln x} = \lim_{x \rightarrow \infty} -\frac{\frac{d}{dx} x}{\frac{d}{dx} \ln x} = \lim_{x \rightarrow \infty} -\frac{1}{\frac{1}{x}} = \lim_{x \rightarrow \infty} -x = -\infty.$$

Finally, because $\lim_{x \rightarrow \infty} \ln y = -\infty$, it follows that

$$\lim_{x \rightarrow \infty} y = \lim_{x \rightarrow \infty} (e^x)^{1/\ln x} = \lim_{x \rightarrow \infty} e^{\ln y} = \boxed{0}.$$

(f) Because

$$\left[\left(\frac{1}{a} \right)^x \right]^{-1/x} = \left(\frac{1}{a} \right)^{-1} = a$$

for all x ,

$$\lim_{x \rightarrow \infty} \left[\left(\frac{1}{a} \right)^x \right]^{-1/x} = \boxed{a}.$$

(g) Because

$$\lim_{x \rightarrow \infty} x = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} \frac{1}{x} = 0,$$

the expression $x^{1/x}$ is an indeterminate form at ∞ of the type ∞^0 . Let $y = x^{1/x}$. Then

$$\ln y = \ln x^{1/x} = \frac{1}{x} \ln x = \frac{\ln x}{x},$$

which is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow \infty} \ln y = \lim_{x \rightarrow \infty} \frac{\ln x}{x} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx} \ln x}{\frac{d}{dx} x} = \lim_{x \rightarrow \infty} \frac{\frac{1}{x}}{1} = \lim_{x \rightarrow \infty} \frac{1}{x} = 0.$$

Finally, because $\lim_{x \rightarrow \infty} \ln y = 0$, it follows that

$$\lim_{x \rightarrow \infty} y = \lim_{x \rightarrow \infty} x^{1/x} = e^0 = \boxed{1}.$$

(h) Because

$$(a^x)^{1/x} = a$$

for all x ,

$$\lim_{x \rightarrow \infty} (a^x)^{1/x} = \boxed{a}.$$

(i) Because

$$[(2 + \sin x)^x]^{1/x} = (2 + \sin x)$$

for all x ,

$$\lim_{x \rightarrow \infty} [(2 + \sin x)^x]^{1/x} = \lim_{x \rightarrow \infty} (2 + \sin x)$$

which $\boxed{\text{does not exist}}$ because $\sin x$ never approaches a single number as $x \rightarrow \infty$.

(j) For $x > 0$,

$$x^{-1/\ln x} = (e^{\ln x})^{-1/\ln x} = e^{-1},$$

so

$$\lim_{x \rightarrow 0^+} x^{-1/\ln x} = \lim_{x \rightarrow 0^+} e^{-1} = \boxed{e^{-1}}.$$

110. Because

$$\lim_{x \rightarrow 0} (\sin(Ax) + Bx + Cx^2 + Dx^3) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} x^5 = 0,$$

the expression $\frac{\sin(Ax) + Bx + Cx^2 + Dx^3}{x^5}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\begin{aligned}\lim_{x \rightarrow 0} \frac{\sin(Ax) + Bx + Cx^2 + Dx^3}{x^5} &= \lim_{x \rightarrow 0} \frac{\frac{d}{dx}(\sin(Ax) + Bx + Cx^2 + Dx^3)}{\frac{d}{dx}x^5} \\ &= \lim_{x \rightarrow 0} \frac{A \cos(Ax) + B + 2Cx + 3Dx^2}{5x^4}.\end{aligned}$$

Now, $\lim_{x \rightarrow 0} (5x^4) = 0$, so

$$\lim_{x \rightarrow 0} [A \cos(Ax) + B + 2Cx + 3Dx^2] = A + B$$

must be equal to 0 in order for the original limit to exist; therefore, $A + B = 0$. Using L'Hôpital's Rule again,

$$\begin{aligned}\lim_{x \rightarrow 0} \frac{\sin(Ax) + Bx + Cx^2 + Dx^3}{x^5} &= \lim_{x \rightarrow 0} \frac{\frac{d}{dx}[A \cos(Ax) + B + 2Cx + 3Dx^2]}{\frac{d}{dx}5x^4} \\ &= \lim_{x \rightarrow 0} \frac{-A^2 \sin(Ax) + 2C + 6Dx}{20x^3}.\end{aligned}$$

As above, because $\lim_{x \rightarrow 0} (20x^3) = 0$,

$$\lim_{x \rightarrow 0} [-A^2 \sin(Ax) + 2C + 6Dx] = 2C$$

must be equal to 0 in order for the original limit to exist; therefore, $C = 0$. Using L'Hôpital's Rule for a third time,

$$\lim_{x \rightarrow 0} \frac{\sin(Ax) + Bx + Cx^2 + Dx^3}{x^5} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx}[-A^2 \sin(Ax) + 2C + 6Dx]}{\frac{d}{dx}20x^3} = \lim_{x \rightarrow 0} \frac{-A^3 \cos(Ax) + 6D}{60x^2}.$$

The requirement that the original limit exist then yields

$$\lim_{x \rightarrow 0} [-A^3 \cos(Ax) + 6D] = -A^3 + 6D = 0.$$

A fourth application of L'Hôpital's Rule gives

$$\lim_{x \rightarrow 0} \frac{\sin(Ax) + Bx + Cx^2 + Dx^3}{x^5} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx}[-A^3 \cos(Ax) + 6D]}{\frac{d}{dx}60x^2} = \lim_{x \rightarrow 0} \frac{A^4 \sin(Ax)}{120x},$$

which involves an indeterminate form at 0 of the type $\frac{0}{0}$. One last use of L'Hôpital's Rule produces

$$\lim_{x \rightarrow 0} \frac{\sin(Ax) + Bx + Cx^2 + Dx^3}{x^5} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx}A^4 \sin(Ax)}{\frac{d}{dx}120x} = \lim_{x \rightarrow 0} \frac{A^5 \cos(Ax)}{120} = \frac{A^5}{120} = \frac{4}{15}.$$

Finally,

$$\boxed{A = 2, \quad B = -2, \quad C = 0, \quad \text{and} \quad D = \frac{4}{3}}.$$

111. Let f be a function whose derivatives of all orders exist.

(a) Because

$$\lim_{h \rightarrow 0} [f(x + 2h) - 2f(x + h) + f(x)] = 0 \quad \text{and} \quad \lim_{h \rightarrow 0} h^2 = 0,$$

the expression $\frac{f(x+2h) - 2f(x+h) + f(x)}{h^2}$ is an indeterminate form at $h = 0$ of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\begin{aligned} \lim_{h \rightarrow 0} \frac{f(x+2h) - 2f(x+h) + f(x)}{h^2} &= \lim_{h \rightarrow 0} \frac{\frac{d}{dh}[f(x+2h) - 2f(x+h) + f(x)]}{\frac{d}{dh}h^2} \\ &= \lim_{h \rightarrow 0} \frac{2f'(x+2h) - 2f'(x+h)}{2h} \\ &= \lim_{h \rightarrow 0} \frac{f'(x+2h) - f'(x+h)}{h}. \end{aligned}$$

Now,

$$\lim_{h \rightarrow 0} [f'(x+2h) - f'(x+h)] = 0 \quad \text{and} \quad \lim_{h \rightarrow 0} h = 0,$$

so the expression $\frac{f'(x+2h) - f'(x+h)}{h}$ is an indeterminate form at $h = 0$ of the type $\frac{0}{0}$. Using L'Hôpital's Rule again,

$$\begin{aligned} \lim_{h \rightarrow 0} \frac{f(x+2h) - 2f(x+h) + f(x)}{h^2} &= \lim_{h \rightarrow 0} \frac{f'(x+2h) - f'(x+h)}{h} \\ &= \lim_{h \rightarrow 0} \frac{\frac{d}{dh}[f'(x+2h) - f'(x+h)]}{\frac{d}{dh}h} \\ &= \lim_{h \rightarrow 0} \frac{2f''(x+2h) - f''(x+h)}{1} = \boxed{f''(x)}. \end{aligned}$$

(b) Because

$$\lim_{h \rightarrow 0} [f(x+3h) - 3f(x+2h) + 3f(x+h) - f(x)] = 0 \quad \text{and} \quad \lim_{h \rightarrow 0} h^3 = 0,$$

the expression $\frac{f(x+3h) - 3f(x+2h) + 3f(x+h) - f(x)}{h^3}$ is an indeterminate form at $h = 0$ of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\begin{aligned} \lim_{h \rightarrow 0} \frac{f(x+3h) - 3f(x+2h) + 3f(x+h) - f(x)}{h^3} &= \lim_{h \rightarrow 0} \frac{\frac{d}{dh}[f(x+3h) - 3f(x+2h) + 3f(x+h) - f(x)]}{\frac{d}{dh}h^3} \\ &= \lim_{h \rightarrow 0} \frac{3f'(x+3h) - 6f'(x+2h) + 3f'(x+h)}{3h^2} \\ &= \lim_{h \rightarrow 0} \frac{f'(x+3h) - 2f'(x+2h) + f'(x+h)}{h^2}. \end{aligned}$$

Now,

$$\lim_{h \rightarrow 0} [f'(x+3h) - 2f'(x+2h) + f'(x+h)] = 0 \quad \text{and} \quad \lim_{h \rightarrow 0} h^2 = 0,$$

so the expression $\frac{f'(x+3h) - 2f'(x+2h) + f'(x+h)}{h^2}$ is an indeterminate form at $h = 0$ of the

type $\frac{0}{0}$. Using L'Hôpital's Rule again,

$$\begin{aligned} \lim_{h \rightarrow 0} \frac{f(x+3h) - 3f(x+2h) + 3f(x+h) - f(x)}{h^3} \\ &= \lim_{h \rightarrow 0} \frac{f'(x+3h) - 2f'(x+2h) + f'(x+h)}{h^2} \\ &= \lim_{h \rightarrow 0} \frac{\frac{d}{dh}[f'(x+3h) - 2f'(x+2h) + f'(x+h)]}{\frac{d}{dh}h^2} \\ &= \lim_{h \rightarrow 0} \frac{3f''(x+3h) - 4f''(x+2h) + f''(x+h)}{2h}. \end{aligned}$$

Finally,

$$\lim_{h \rightarrow 0} [3f''(x+3h) - 4f''(x+2h) + f''(x+h)] = 0 \quad \text{and} \quad \lim_{h \rightarrow 0} (2h) = 0,$$

so the expression $\frac{3f''(x+3h) - 4f''(x+2h) + f''(x+h)}{2h}$ is an indeterminate form at $h = 0$ of the type $\frac{0}{0}$. Using L'Hôpital's Rule a third time

$$\begin{aligned} \lim_{h \rightarrow 0} \frac{f(x+3h) - 3f(x+2h) + 3f(x+h) - f(x)}{h^3} \\ &= \lim_{h \rightarrow 0} \frac{3f''(x+3h) - 4f''(x+2h) + f''(x+h)}{2h} \\ &= \lim_{h \rightarrow 0} \frac{\frac{d}{dh}[3f''(x+3h) - 4f''(x+2h) + f''(x+h)]}{\frac{d}{dh}(2h)} \\ &= \lim_{h \rightarrow 0} \frac{9f'''(x+3h) - 8f'''(x+2h) + f'''(x+h)}{2} \\ &= \frac{2f'''(x)}{2} = \boxed{f'''(x)}. \end{aligned}$$

- (c) Recognize that in the numerator of each limit, the coefficients on the values of f (1, -2, 1 in part (a) and 1, -3, 3, -1 in part (b)) are the coefficients in $(x-1)^2$ and $(x-1)^3$, respectively; that is, they are binomial coefficients. Therefore, for a positive integer n ,

$$\boxed{\lim_{h \rightarrow 0} \frac{\sum_{k=0}^n (-1)^k \frac{n!}{k!(n-k)!} f(x + (n-k)h)}{h^n} = f^{(n)}(x)}.$$

112. Using the data provided and the results of Problem 111 with $h = 0.1$,

$$\begin{aligned} f'(2) &\approx \frac{f(2.1) - f(2)}{0.1} = \frac{0.7419 - 0.6931}{0.1} = \boxed{0.488}; \\ f''(2) &\approx \frac{f(2.2) - 2f(2.1) + f(2)}{(0.1)^2} = \frac{0.7885 - 2(0.7419) + 0.6931}{0.01} = \boxed{-0.22}; \text{ and} \\ f'''(2) &\approx \frac{f(2.3) - 3f(2.2) + 3f(2.1) - f(2)}{(0.1)^3} = \frac{0.8329 - 3(0.7885) + 3(0.7419) - 0.6931}{0.001} = \boxed{0}. \end{aligned}$$

With $f(x) = \ln x$,

$$f'(x) = \frac{1}{x}, \quad f''(x) = -\frac{1}{x^2}, \quad \text{and} \quad f'''(x) = \frac{2}{x^3},$$

so

$$f'(2) = \frac{1}{2}, \quad f''(2) = -\frac{1}{4}, \quad \text{and} \quad f'''(2) = \frac{1}{4}.$$

The percentage error in the approximation to the value of the first derivative is $\boxed{2.4\%}$; the percentage error in the approximation to the value of the second derivative is $\boxed{12\%}$; the percentage error in the approximation to the value of the third derivative is $\boxed{100\%}$.

113. Let $f(t, x) = \frac{x^{t+1} - 1}{t + 1}$, where $x > 0$ and $t \neq -1$.

(a) Let $x = x_0$. Because

$$\lim_{t \rightarrow -1} (x_0^{t+1} - 1) = 0 \quad \text{and} \quad \lim_{t \rightarrow -1} (t + 1) = 0,$$

the expression $f(t, x_0) = \frac{x_0^{t+1} - 1}{t + 1}$ is an indeterminate form at $t = -1$ of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\begin{aligned} \lim_{t \rightarrow -1} f(t, x_0) &= \lim_{t \rightarrow -1} \frac{x_0^{t+1} - 1}{t + 1} = \lim_{t \rightarrow -1} \frac{\frac{d}{dt}(x_0^{t+1} - 1)}{\frac{d}{dt}(t + 1)} \\ &= \lim_{t \rightarrow -1} \frac{x_0^{t+1} \ln x_0}{1} = \ln x_0. \end{aligned}$$

(b) The function $f(t, x)$ is continuous for $t \neq -1$. Based on the result from part (a), define

$$F(t, x) = \begin{cases} f(t, x), & t \neq -1 \\ \ln x, & t = -1. \end{cases}$$

The function $F(t, x)$ is then continuous for all t .

(c) Based on part (b), for t fixed but not equal to -1 ,

$$\frac{d}{dx} F(t, x) = \frac{d}{dx} f(t, x) = \frac{d}{dx} \left(\frac{x^{t+1} - 1}{t + 1} \right) = \frac{1}{t + 1} \cdot (t + 1)x^t = x^t.$$

For $t = -1$,

$$\frac{d}{dx} F(t, x) = \frac{d}{dx} \ln x = \frac{1}{x} = x^{-1} = x^t.$$

4.6: Using Calculus to Graph Functions

Skill Building

1. Let $f(x) = x^4 - 6x^2 + 10$.

Step 1 The polynomial function f has a domain of all real numbers. $f(0) = 10$, so the y -intercept is 10.
To find the x -intercepts, solve the equation $f(x) = 0$. Because

$$x^4 - 6x^2 + 10 = (x^2 - 3)^2 + 1,$$

it follows that there are no real solutions to the equation $f(x) = 0$, so the graph of f has no x -intercepts.

Step 2 The graphs of polynomial functions do not have asymptotes, but the end behavior of the graph of f will resemble the power function $y = x^4$.

Step 3 Now

$$\begin{aligned} f'(x) &= 4x^3 - 12x = 4x(x^2 - 3); \text{ and} \\ f''(x) &= 12x^2 - 12 = 12(x - 1)(x + 1). \end{aligned}$$

The critical numbers of the polynomial function f occur where $f'(x) = 0$, so 0 and $\pm\sqrt{3}$ are the critical numbers. At the points $(-\sqrt{3}, 1)$, $(0, 10)$, and $(\sqrt{3}, 1)$, the tangent lines are horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the critical numbers 0 and $\pm\sqrt{3}$ to divide the number line into four intervals.

Interval	Sign of f'	Conclusion
$(-\infty, -\sqrt{3})$	–	f is decreasing on $(-\infty, -\sqrt{3})$
$(-\sqrt{3}, 0)$	+	f is increasing on $(-\sqrt{3}, 0)$
$(0, \sqrt{3})$	–	f is decreasing on $(0, \sqrt{3})$
$(\sqrt{3}, \infty)$	+	f is increasing on $(\sqrt{3}, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local minimum value at $-\sqrt{3}$, a local maximum value at 0, and a local minimum value at $\sqrt{3}$. The

$$\text{local minimum values are } f(-\sqrt{3}) = 1 \text{ and } f(\sqrt{3}) = 1,$$

while the local maximum value is $f(0) = 10$.

Step 6 The second derivative is equal to zero at $x = \pm 1$. Use these numbers to divide the number line into three intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, -1)$	+	f is concave up on $(-\infty, -1)$
$(-1, 1)$	–	f is concave down on $(-1, 1)$
$(1, \infty)$	+	f is concave up on $(1, \infty)$

The concavity of f changes at ± 1 , so the points $(-1, 5)$ and $(1, 5)$ are points of inflection of f .

Step 7 The figure below displays the graph of f . Local extreme values are highlighted by closed circles, and points of inflection are highlighted by closed squares.

2. Let $f(x) = x^5 - 3x^3 + 4$.

Step 1 The polynomial function f has a domain of all real numbers. $f(0) = 4$, so the y -intercept is 4. To find the x -intercepts, solve the equation $f(x) = 0$. Using the computer algebra system *Maple*, the only real number solution of the equation $f(x) = 0$ is $x \approx -1.894$. Therefore, -1.894 is the approximate x -intercept of f .

Step 2 The graphs of polynomial functions do not have asymptotes, but the end behavior of the graph of f will resemble the power function $y = x^5$.

Step 3 Now

$$\begin{aligned} f'(x) &= 5x^4 - 9x^2 = x^2(5x^2 - 9); \text{ and} \\ f''(x) &= 20x^3 - 18x = 2x(10x^2 - 9). \end{aligned}$$

The critical numbers of the polynomial function f occur where $f'(x) = 0$, so 0 and $\pm \frac{3\sqrt{5}}{5}$ are the critical numbers. At the points

$$\left(-\frac{3\sqrt{5}}{5}, \frac{500 + 162\sqrt{5}}{125}\right), \quad (0, 4), \quad \left(\frac{3\sqrt{5}}{5}, \frac{500 - 162\sqrt{5}}{125}\right),$$

the tangent lines are horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the critical numbers 0 and $\pm \frac{3\sqrt{5}}{5}$ to divide the number line into four intervals.

Interval	Sign of f'	Conclusion
$(-\infty, -\frac{3\sqrt{5}}{5})$	+	f is increasing on $(-\infty, -\frac{3\sqrt{5}}{5})$
$(-\frac{3\sqrt{5}}{5}, 0)$	-	f is decreasing on $(-\frac{3\sqrt{5}}{5}, 0)$
$(0, \frac{3\sqrt{5}}{5})$	-	f is decreasing on $(0, \frac{3\sqrt{5}}{5})$
$(\frac{3\sqrt{5}}{5}, \infty)$	+	f is increasing on $(\frac{3\sqrt{5}}{5}, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local maximum value at $-\frac{3\sqrt{5}}{5}$, neither a local maximum value nor a local minimum at 0 , and a local minimum value at $\frac{3\sqrt{5}}{5}$. The

local maximum value is $f\left(-\frac{3\sqrt{5}}{5}\right) = \frac{500 + 162\sqrt{5}}{125}$,

while the

$$\text{local minimum value is } f\left(\frac{3\sqrt{5}}{5}\right) = \frac{500 - 162\sqrt{5}}{125}.$$

Step 6 The second derivative is equal to zero at $x = 0$ and $x = \pm \frac{3\sqrt{10}}{10}$. Use these numbers to divide the number line into four intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, -\frac{3\sqrt{10}}{10})$	−	f is concave down on $(-\infty, -\frac{3\sqrt{10}}{10})$
$(-\frac{3\sqrt{10}}{10}, 0)$	+	f is concave up on $(-\frac{3\sqrt{10}}{10}, 0)$
$(0, \frac{3\sqrt{10}}{10})$	−	f is concave down on $(0, \frac{3\sqrt{10}}{10})$
$(\frac{3\sqrt{10}}{10}, \infty)$	+	f is concave up on $(\frac{3\sqrt{10}}{10}, \infty)$

The concavity of f changes at 0 and $\pm \frac{3\sqrt{10}}{10}$, so the points

$$\left(-\frac{3\sqrt{10}}{10}, \frac{4000 + 567\sqrt{10}}{1000}\right), \quad (0, 4), \quad \left(\frac{3\sqrt{10}}{10}, \frac{4000 - 567\sqrt{10}}{1000}\right),$$

are points of inflection of f .

Step 7 The figure below displays the graph of f . Local extreme values are highlighted by closed circles, and points of inflection are highlighted by closed squares.

3. Let $f(x) = \frac{1}{x-2}$.

Step 1 The domain of the rational function f is the set $\{x|x \neq 2\}$. There are no x -intercepts, and the

$$y\text{-intercept is } f(0) = -\frac{1}{2}.$$

Step 2 The degree of the numerator is less than the degree of the denominator, so the graph of f has a horizontal asymptote. Because

$$\lim_{x \rightarrow \pm\infty} \frac{1}{x-2} = \lim_{x \rightarrow \pm\infty} \frac{1}{x-2} \cdot \frac{\frac{1}{x}}{\frac{1}{x}} = \lim_{x \rightarrow \pm\infty} \frac{\frac{1}{x}}{1 - \frac{2}{x}} = 0,$$

the line $y = 0$ is a horizontal asymptote. To identify vertical asymptotes, check the one-sided limits at those values for x that are not in the domain of f . As

$$\lim_{x \rightarrow 2^-} \frac{1}{x-2} = -\infty \quad \text{and} \quad \lim_{x \rightarrow 2^+} \frac{1}{x-2} = \infty,$$

the line $x = 2$ is a vertical asymptote.

Step 3 Now

$$\begin{aligned} f'(x) &= \frac{d}{dx}(x-2)^{-1} = -(x-2)^{-2} = -\frac{1}{(x-2)^2}; \text{ and} \\ f''(x) &= \frac{d}{dx}[-(x-2)^{-2}] = 2(x-2)^{-3} = \frac{2}{(x-2)^3}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. Note $f'(x)$ is never equal to 0 and does not exist when $x = 2$. However, 2 is not in the domain of f , so 2 is not a critical number. Therefore, f has no critical numbers.

Step 4 To apply the Increasing/Decreasing Function Test, use the number 2 to divide the number line into two intervals.

Interval	Sign of f'	Conclusion
$(-\infty, 2)$	—	f is decreasing on $(-\infty, 2)$
$(2, \infty)$	—	f is decreasing on $(2, \infty)$

Step 5 Because there are no critical numbers, f has no local extreme values.

Step 6 The second derivative is never equal to zero and does not exist when $x = 2$. Use this number to divide the number line into two intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, 2)$	—	f is concave down on $(-\infty, 2)$
$(2, \infty)$	+	f is concave up on $(2, \infty)$

Although the concavity of f changes at 2, there is no point of inflection at 2 because 2 is not in the domain of f .

Step 7 The figure below displays the graph of f .

4. Let $f(x) = \frac{2}{x+2}$.

Step 1 The domain of the rational function f is the set $\{x|x \neq -2\}$. There are no x -intercepts, and the y -intercept is $f(0) = 1$.

Step 2 The degree of the numerator is less than the degree of the denominator, so the graph of f has a horizontal asymptote. Because

$$\lim_{x \rightarrow \pm\infty} \frac{2}{x+2} = \lim_{x \rightarrow \pm\infty} \frac{2}{x+2} \cdot \frac{\frac{1}{x}}{\frac{1}{x}} = \lim_{x \rightarrow \pm\infty} \frac{\frac{2}{x}}{1 + \frac{2}{x}} = 0,$$

the line $y = 0$ is a horizontal asymptote. To identify vertical asymptotes, check the one-sided limits at those values for x that are not in the domain of f . As

$$\lim_{x \rightarrow -2^-} \frac{2}{x+2} = -\infty \quad \text{and} \quad \lim_{x \rightarrow -2^+} \frac{2}{x+2} = \infty,$$

the line $x = -2$ is a vertical asymptote.

Step 3 Now

$$\begin{aligned} f'(x) &= \frac{d}{dx} 2(x+2)^{-1} = -2(x+2)^{-2} = -\frac{2}{(x+2)^2}; \text{ and} \\ f''(x) &= \frac{d}{dx} [-2(x+2)^{-2}] = 4(x+2)^{-3} = \frac{4}{(x+2)^3}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. Note $f'(x)$ is never equal to 0 and does not exist when $x = -2$. However, -2 is not in the domain of f , so -2 is not a critical number. Therefore, f has no critical numbers.

Step 4 To apply the Increasing/Decreasing Function Test, use the number -2 to divide the number line into two intervals.

Interval	Sign of f'	Conclusion
$(-\infty, -2)$	—	f is decreasing on $(-\infty, -2)$
$(-2, \infty)$	—	f is decreasing on $(-2, \infty)$

Step 5 Because there are no critical numbers, f has no local extreme values.

Step 6 The second derivative is never equal to zero and does not exist when $x = -2$. Use this number to divide the number line into two intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, -2)$	—	f is concave down on $(-\infty, -2)$
$(-2, \infty)$	+	f is concave up on $(-2, \infty)$

Although the concavity of f changes at -2 , there is no point of inflection at -2 because -2 is not in the domain of f .

Step 7 The figure below displays the graph of f .

5. Let $f(x) = \frac{2}{x^2 - 4}$.

Step 1 The domain of the rational function f is the set $\{x|x \neq \pm 2\}$. There are no x -intercepts, and the y -intercept is $f(0) = -\frac{1}{2}$.

Step 2 The degree of the numerator is less than the degree of the denominator, so the graph of f has a horizontal asymptote. Because

$$\lim_{x \rightarrow \pm\infty} \frac{2}{x^2 - 4} = \lim_{x \rightarrow \pm\infty} \frac{2}{x^2 - 4} \cdot \frac{\frac{1}{x^2}}{\frac{1}{x^2}} = \lim_{x \rightarrow \pm\infty} \frac{\frac{2}{x^2}}{1 - \frac{4}{x^2}} = 0,$$

the line $y = 0$ is a horizontal asymptote. To identify vertical asymptotes, check the one-sided limits at those values for x that are not in the domain of f . As

$$\lim_{x \rightarrow -2^-} \frac{2}{x^2 - 4} = \infty \quad \text{and} \quad \lim_{x \rightarrow -2^+} \frac{2}{x^2 - 4} = -\infty,$$

and

$$\lim_{x \rightarrow 2^-} \frac{2}{x^2 - 4} = -\infty \quad \text{and} \quad \lim_{x \rightarrow 2^+} \frac{2}{x^2 - 4} = \infty,$$

the lines $x = \pm 2$ are vertical asymptotes.

Step 3 Now

$$\begin{aligned} f'(x) &= \frac{d}{dx} 2(x^2 - 4)^{-1} = -2(x^2 - 4)^{-2} \cdot 2x = -\frac{4x}{(x^2 - 4)^2}; \text{ and} \\ f''(x) &= \frac{d}{dx} \left[-\frac{4x}{(x^2 - 4)^2} \right] = -\frac{(x^2 - 4)^2 \cdot 4 - 4x \cdot 2(x^2 - 4)(2x)}{(x^2 - 4)^4} \\ &= -\frac{4(x^2 - 4) - 16x^2}{(x^2 - 4)^3} = \frac{12x^2 + 16}{(x^2 - 4)^3}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is equal to 0 when $x = 0$ and does not exist when $x = \pm 2$. However, ± 2 are not in the domain of f , so ± 2 are not critical numbers. Therefore, 0 is the only critical number of f . The tangent line at the point $\left(0, -\frac{1}{2}\right)$ is horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the numbers 0 and ± 2 to divide the number line into four intervals.

Interval	Sign of f'	Conclusion
$(-\infty, -2)$	+	f is increasing on $(-\infty, -2)$
$(-2, 0)$	+	f is increasing on $(-2, 0)$
$(0, 2)$	-	f is decreasing on $(0, 2)$
$(2, \infty)$	-	f is decreasing on $(2, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local maximum value at 0. The local maximum value is $f(0) = -\frac{1}{2}$.

Step 6 The second derivative is never equal to zero and does not exist when $x = \pm 2$. Use these numbers to divide the number line into three intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, -2)$	+	f is concave up on $(-\infty, -2)$
$(-2, 2)$	-	f is concave down on $(-2, 2)$
$(2, \infty)$	+	f is concave up on $(2, \infty)$

Although the concavity of f changes at ± 2 , there is no point of inflection at ± 2 because ± 2 are not in the domain of f .

Step 7 The figure below displays the graph of f . The local extreme value is highlighted by a closed circle.

6. Let $f(x) = \frac{1}{x^2 - 1}$.

Step 1 The domain of the rational function f is the set $\{x | x \neq \pm 1\}$. There are no x -intercepts, and the y -intercept is $f(0) = -1$.

Step 2 The degree of the numerator is less than the degree of the denominator, so the graph of f has a horizontal asymptote. Because

$$\lim_{x \rightarrow \pm\infty} \frac{1}{x^2 - 1} = \lim_{x \rightarrow \pm\infty} \frac{1}{x^2 - 1} \cdot \frac{\frac{1}{x^2}}{\frac{1}{x^2}} = \lim_{x \rightarrow \pm\infty} \frac{\frac{1}{x^2}}{1 - \frac{1}{x^2}} = 0,$$

the line $y = 0$ is a horizontal asymptote. To identify vertical asymptotes, check the one-sided limits at those values for x that are not in the domain of f . As

$$\lim_{x \rightarrow -1^-} \frac{1}{x^2 - 1} = \infty \quad \text{and} \quad \lim_{x \rightarrow -1^+} \frac{1}{x^2 - 1} = -\infty,$$

and

$$\lim_{x \rightarrow 1^-} \frac{1}{x^2 - 1} = -\infty \quad \text{and} \quad \lim_{x \rightarrow 1^+} \frac{1}{x^2 - 1} = \infty,$$

the lines $x = \pm 1$ are vertical asymptotes.

Step 3 Now

$$\begin{aligned} f'(x) &= \frac{d}{dx}(x^2 - 1)^{-1} = -(x^2 - 1)^{-2} \cdot 2x = -\frac{2x}{(x^2 - 1)^2}; \text{ and} \\ f''(x) &= \frac{d}{dx} \left[-\frac{2x}{(x^2 - 1)^2} \right] = -\frac{(x^2 - 1)^2 \cdot 2 - 2x \cdot 2(x^2 - 1)(2x)}{(x^2 - 1)^4} \\ &= -\frac{2(x^2 - 1) - 8x^2}{(x^2 - 1)^3} = \frac{6x^2 + 2}{(x^2 - 1)^3}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is equal to 0 when $x = 0$ and does not exist when $x = \pm 1$. However, ± 1 are not in the domain of f , so ± 1 are not critical numbers. Therefore, 0 is the only critical number of f . the tangent line at the point $(0, -1)$ is horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the numbers 0 and ± 1 to divide the number line into four intervals.

Interval	Sign of f'	Conclusion
$(-\infty, -1)$	+	f is increasing on $(-\infty, -1)$
$(-1, 0)$	+	f is increasing on $(-1, 0)$
$(0, 1)$	-	f is decreasing on $(0, 1)$
$(1, \infty)$	-	f is decreasing on $(1, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local maximum value at 0. The local maximum value is $f(0) = -1$.

Step 6 The second derivative is never equal to zero and does not exist when $x = \pm 1$. Use these numbers to divide the number line into three intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, -1)$	+	f is concave up on $(-\infty, -1)$
$(-1, 1)$	-	f is concave down on $(-1, 1)$
$(1, \infty)$	+	f is concave up on $(1, \infty)$

Although the concavity of f changes at ± 1 , there is no point of inflection at ± 1 because ± 1 are not in the domain of f .

Step 7 The figure below displays the graph of f . The local extreme value is highlighted by a closed circle.

7. Let $f(x) = \frac{2x-1}{x+1}$.

Step 1 The domain of the rational function f is the set $\{x|x \neq -1\}$. The x -intercept is $\frac{1}{2}$, and the y -intercept is $f(0) = -1$.

Step 2 The degree of the numerator is equal to the degree of the denominator, so the graph of f has a horizontal asymptote. Because

$$\lim_{x \rightarrow \pm\infty} \frac{2x-1}{x+1} = \lim_{x \rightarrow \pm\infty} \frac{2x-1}{x+1} \cdot \frac{\frac{1}{x}}{\frac{1}{x}} = \lim_{x \rightarrow \pm\infty} \frac{2 - \frac{1}{x}}{1 + \frac{1}{x}} = 2,$$

the line $y = 2$ is a horizontal asymptote. To identify vertical asymptotes, check the one-sided limits at those values for x that are not in the domain of f . As

$$\lim_{x \rightarrow -1^-} \frac{2x-1}{x+1} = \infty \quad \text{and} \quad \lim_{x \rightarrow -1^+} \frac{2x-1}{x+1} = -\infty,$$

the line $x = -1$ is a vertical asymptote.

Step 3 Now

$$\begin{aligned} f'(x) &= \frac{d}{dx} \left(\frac{2x-1}{x+1} \right) = \frac{(x+1) \cdot 2 - (2x-1) \cdot 1}{(x+1)^2} = \frac{3}{(x+1)^2}; \text{ and} \\ f''(x) &= \frac{d}{dx} [3(x+1)^{-2}] = -6(x+1)^{-3} = -\frac{6}{(x+1)^3}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is never equal to 0 and does not exist when $x = -1$. However, -1 is not in the domain of f , so -1 is not a critical number. Therefore, f has no critical numbers.

Step 4 To apply the Increasing/Decreasing Function Test, use the number -1 to divide the number line into two intervals.

Interval	Sign of f'	Conclusion
$(-\infty, -1)$	+	f is increasing on $(-\infty, -1)$
$(-1, \infty)$	+	f is increasing on $(-1, \infty)$

Step 5 Because there are no critical numbers, f has no local extreme values.

Step 6 The second derivative is never equal to zero and does not exist when $x = -1$. Use this number to divide the number line into two intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, -1)$	+	f is concave up on $(-\infty, -1)$
$(-1, \infty)$	-	f is concave down on $(-1, \infty)$

Although the concavity of f changes at -1 , there is no point of inflection at -1 because -1 is not in the domain of f .

Step 7 The figure below displays the graph of f .

8. Let $f(x) = \frac{x-2}{x}$.

Step 1 The domain of the rational function f is the set $\{x|x \neq 0\}$. The x -intercept is 2, and there is no y -intercept because f is not defined at 0.

Step 2 The degree of the numerator is equal to the degree of the denominator, so the graph of f has a horizontal asymptote. Because

$$\lim_{x \rightarrow \pm\infty} \frac{x-2}{x} = \lim_{x \rightarrow \pm\infty} \frac{x-2}{x} \cdot \frac{\frac{1}{x}}{\frac{1}{x}} = \lim_{x \rightarrow \pm\infty} \frac{1 - \frac{2}{x}}{1} = 1,$$

the line $y = 1$ is a horizontal asymptote. To identify vertical asymptotes, check the one-sided limits at those values for x that are not in the domain of f . As

$$\lim_{x \rightarrow 0^-} \frac{x-2}{x} = \infty \quad \text{and} \quad \lim_{x \rightarrow 0^+} \frac{x-2}{x} = -\infty,$$

the line $x = 0$ is a vertical asymptote.

Step 3 Now

$$\begin{aligned} f'(x) &= \frac{d}{dx} \left(\frac{x-2}{x} \right) = \frac{x \cdot 1 - (x-2) \cdot 1}{x^2} = \frac{2}{x^2}; \text{ and} \\ f''(x) &= \frac{d}{dx} [2x^{-2}] = -4x^{-3} = -\frac{4}{x^3}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is never equal to 0 and does not exist when $x = 0$. However, 0 is not in the domain of f , so 0 is not a critical number. Therefore, f has no critical numbers.

Step 4 To apply the Increasing/Decreasing Function Test, use the number 0 to divide the number line into two intervals.

Interval	Sign of f'	Conclusion
$(-\infty, 0)$	+	f is increasing on $(-\infty, 0)$
$(0, \infty)$	+	f is increasing on $(0, \infty)$

Step 5 Because there are no critical numbers, f has no local extreme values.

Step 6 The second derivative is never equal to zero and does not exist when $x = 0$. Use this number to divide the number line into two intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, 0)$	+	f is concave up on $(-\infty, 0)$
$(0, \infty)$	-	f is concave down on $(0, \infty)$

Although the concavity of f changes at 0, there is no point of inflection at 0 because 0 is not in the domain of f .

Step 7 The figure below displays the graph of f .

9. Let $f(x) = \frac{x}{x^2 + 1}$.

Step 1 The domain of the rational function f is the set of all real numbers (because $1 + x^2$ is never equal to zero for any real x). The x -intercept is 0, and the y -intercept is $f(0) = 0$.

Step 2 The degree of the numerator is less than the degree of the denominator, so the graph of f has a horizontal asymptote. Because

$$\lim_{x \rightarrow \pm\infty} \frac{x}{x^2 + 1} = \lim_{x \rightarrow \pm\infty} \frac{x}{x^2 + 1} \cdot \frac{\frac{1}{x^2}}{\frac{1}{x^2}} = \lim_{x \rightarrow \pm\infty} \frac{\frac{1}{x}}{1 + \frac{1}{x^2}} = 0,$$

the line $y = 0$ is a horizontal asymptote. Because f is defined for all real numbers, there are no vertical asymptotes.

Step 3 Now

$$\begin{aligned} f'(x) &= \frac{d}{dx} \left(\frac{x}{x^2 + 1} \right) = \frac{(x^2 + 1) \cdot 1 - x \cdot 2x}{(x^2 + 1)^2} = \frac{1 - x^2}{(x^2 + 1)^2}; \text{ and} \\ f''(x) &= \frac{d}{dx} \left(\frac{1 - x^2}{(x^2 + 1)^2} \right) = \frac{(x^2 + 1)^2 \cdot (-2x) - (1 - x^2) \cdot 2(x^2 + 1)(2x)}{(x^2 + 1)^4} \\ &= \frac{-2x(x^2 + 1) - 4x(1 - x^2)}{(x^2 + 1)^3} = \frac{2x^3 - 6x}{(x^2 + 1)^3}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ exists everywhere and is equal to 0 when $x = \pm 1$. Therefore, ± 1 are the critical numbers of f . At the points $\left(-1, -\frac{1}{2}\right)$ and $\left(1, \frac{1}{2}\right)$, the tangent lines are horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the critical numbers ± 1 to divide the number line into three intervals.

Interval	Sign of f'	Conclusion
$(-\infty, -1)$	$-$	f is decreasing on $(-\infty, -1)$
$(-1, 1)$	$+$	f is increasing on $(-1, 1)$
$(1, \infty)$	$-$	f is decreasing on $(0, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local minimum value at -1 and a local maximum value at 1 . The local minimum value is $f(-1) = -\frac{1}{2}$, and the

$$\text{local maximum value is } f(1) = \frac{1}{2}.$$

Step 6 The second derivative exists everywhere and is equal to 0 when $x = 0$ and when $x = \pm\sqrt{3}$. Use these numbers to divide the number line into four intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, -\sqrt{3})$	$-$	f is concave down on $(-\infty, -\sqrt{3})$
$(-\sqrt{3}, 0)$	$+$	f is concave up on $(-\sqrt{3}, 0)$
$(0, \sqrt{3})$	$-$	f is concave down on $(0, \sqrt{3})$
$(\sqrt{3}, \infty)$	$+$	f is concave up on $(\sqrt{3}, \infty)$

The concavity of f changes at $-\sqrt{3}$, 0 , and $\sqrt{3}$, so the points

$$\left(-\sqrt{3}, -\frac{\sqrt{3}}{4} \right), \quad (0, 0), \quad \text{and} \quad \left(\sqrt{3}, \frac{\sqrt{3}}{4} \right)$$

are points of inflection of f .

Step 7 The figure below displays the graph of f . Local extreme values are highlighted by closed circles, and points of inflection are highlighted by closed squares.

10. Let $f(x) = \frac{2x}{x^2 - 4}$.

Step 1 The domain of the rational function f is the set $\{x | x \neq \pm 2\}$. The x -intercept is 0 , and the y -intercept is $f(0) = 0$.

Step 2 The degree of the numerator is less than the degree of the denominator, so the graph of f has a horizontal asymptote. Because

$$\lim_{x \rightarrow \pm\infty} \frac{2x}{x^2 - 4} = \lim_{x \rightarrow \pm\infty} \frac{2x}{x^2 - 4} \cdot \frac{\frac{1}{x^2}}{\frac{1}{x^2}} = \lim_{x \rightarrow \pm\infty} \frac{\frac{2}{x}}{1 - \frac{4}{x^2}} = 0,$$

the line $y = 0$ is a horizontal asymptote. To identify vertical asymptotes, check the one-sided limits at those values for x that are not in the domain of f . As

$$\lim_{x \rightarrow -2^-} \frac{2x}{x^2 - 4} = -\infty \quad \text{and} \quad \lim_{x \rightarrow -2^+} \frac{2x}{x^2 - 4} = \infty,$$

and

$$\lim_{x \rightarrow 2^-} \frac{2x}{x^2 - 4} = -\infty \quad \text{and} \quad \lim_{x \rightarrow 2^+} \frac{2x}{x^2 - 4} = \infty,$$

the lines $x = \pm 2$ are vertical asymptotes.

Step 3 Now

$$\begin{aligned} f'(x) &= \frac{d}{dx} \left(\frac{2x}{x^2 - 4} \right) = \frac{(x^2 - 4) \cdot 2 - 2x \cdot 2x}{(x^2 - 4)^2} = -\frac{2x^2 + 8}{(x^2 - 4)^2}; \text{ and} \\ f''(x) &= \frac{d}{dx} \left[-\frac{2x^2 + 8}{(x^2 - 4)^2} \right] = -\frac{(x^2 - 4)^2 \cdot 4x - (2x^2 + 8) \cdot 2(x^2 - 4)(2x)}{(x^2 - 4)^4} \\ &= -\frac{4x(x^2 - 4) - 4x(2x^2 + 8)}{(x^2 - 4)^3} = \frac{4x(x^2 + 12)}{(x^2 - 4)^3}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is never equal to 0 and does not exist when $x = \pm 2$. However, ± 2 are not in the domain of f , so ± 2 are not critical numbers. Therefore, f has no critical numbers.

Step 4 To apply the Increasing/Decreasing Function Test, use the numbers ± 2 to divide the number line into three intervals.

Interval	Sign of f'	Conclusion
$(-\infty, -2)$	—	f is decreasing on $(-\infty, -2)$
$(-2, 2)$	—	f is decreasing on $(-2, 2)$
$(2, \infty)$	—	f is decreasing on $(2, \infty)$

Step 5 Because there are no critical numbers, f has no local extreme values.

Step 6 The second derivative is equal to zero when $x = 0$ and does not exist when $x = \pm 2$. Use these numbers to divide the number line into four intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, -2)$	—	f is concave down on $(-\infty, -2)$
$(-2, 0)$	+	f is concave up on $(-2, 0)$
$(0, 2)$	—	f is concave down on $(0, 2)$
$(2, \infty)$	+	f is concave up on $(2, \infty)$

The concavity of f changes at 0, so the point $(0, 0)$ is a point of inflection of f . Although the concavity of f changes at ± 2 , there is no point of inflection at ± 2 because ± 2 are not in the domain of f .

Step 7 The figure below displays the graph of f . The inflection point is highlighted by a closed square.

11. Let $f(x) = \frac{x^2 + 1}{2x}$.

Step 1 The domain of the rational function f is the set $\{x|x \neq 0\}$. There are no x -intercepts because $x^2 + 1$ is never equal to zero for any real x , and there is no y -intercept because f is not defined at 0.

Step 2 The degree of the numerator is one more than the degree of the denominator, so the graph of f has no horizontal asymptote but does have an oblique asymptote. Because

$$f(x) = \frac{x^2 + 1}{2x} = \frac{1}{2}x + \frac{1}{2x},$$

it follows that

$$\lim_{x \rightarrow \infty} \left[f(x) - \frac{1}{2}x \right] = \lim_{x \rightarrow \infty} \frac{1}{2x} = 0$$

so the line $y = \frac{1}{2}x$ is an oblique asymptote. To identify vertical asymptotes, check the one-sided limits at those values for x that are not in the domain of f . As

$$\lim_{x \rightarrow 0^-} \frac{x^2 + 1}{2x} = -\infty \quad \text{and} \quad \lim_{x \rightarrow 0^+} \frac{x^2 + 1}{2x} = \infty,$$

the line $x = 0$ is a vertical asymptote.

Step 3 Now

$$\begin{aligned} f'(x) &= \frac{d}{dx} \left(\frac{x^2 + 1}{2x} \right) = \frac{2x \cdot 2x - (x^2 + 1) \cdot 2}{4x^2} = \frac{2x^2 - 2}{4x^2} = \frac{(x-1)(x+1)}{2x^2}; \text{ and} \\ f''(x) &= \frac{d}{dx} \left[\frac{x^2 - 1}{2x^2} \right] = \frac{2x^2 \cdot 2x - (x^2 - 1) \cdot 4x}{4x^4} = \frac{4x}{4x^4} = \frac{1}{x^3}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is equal to 0 when $x = \pm 1$ and does not exist when $x = 0$. However, 0 is not in the domain of f , so 0 is not a critical number. Therefore, ± 1 are the only critical numbers of f . At the points $(-1, -1)$ and $(1, 1)$, the tangent lines are horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the numbers 0 and ± 1 to divide the number line into four intervals.

Interval	Sign of f'	Conclusion
$(-\infty, -1)$	+	f is increasing on $(-\infty, -1)$
$(-1, 0)$	-	f is decreasing on $(-1, 0)$
$(0, 1)$	-	f is decreasing on $(0, 1)$
$(1, \infty)$	+	f is increasing on $(1, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local maximum value at -1 and a local minimum value at 1 . The local maximum value is $f(-1) = -1$, and the local minimum value is $f(1) = 1$.

Step 6 The second derivative is never equal to zero and does not exist when $x = 0$. Use this number to divide the number line into two intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, 0)$	-	f is concave down on $(-\infty, 0)$
$(0, \infty)$	+	f is concave up on $(0, \infty)$

Although the concavity of f changes at 0 , there is no point of inflection at 0 because 0 is not in the domain of f .

Step 7 The figure below displays the graph of f . The local extreme values are highlighted by a closed circles.

12. Let $f(x) = \frac{x^2 - 1}{2x}$.

Step 1 The domain of the rational function f is the set $\{x|x \neq 0\}$. The x -intercepts are ± 1 , and there is no y -intercept because f is not defined at 0 .

Step 2 The degree of the numerator is one more than the degree of the denominator, so the graph of f has no horizontal asymptote but does have an oblique asymptote. Because

$$f(x) = \frac{x^2 - 1}{2x} = \frac{1}{2}x - \frac{1}{2x},$$

it follows that

$$\lim_{x \rightarrow \infty} \left[f(x) - \frac{1}{2}x \right] = \lim_{x \rightarrow \infty} \left(-\frac{1}{2x} \right) = 0$$

so the line $y = \frac{1}{2}x$ is an oblique asymptote. To identify vertical asymptotes, check the one-sided limits at those values for x that are not in the domain of f . As

$$\lim_{x \rightarrow 0^-} \frac{x^2 - 1}{2x} = \infty \quad \text{and} \quad \lim_{x \rightarrow 0^+} \frac{x^2 - 1}{2x} = -\infty,$$

the line $x = 0$ is a vertical asymptote.

Step 3 Now

$$\begin{aligned} f'(x) &= \frac{d}{dx} \left(\frac{x^2 - 1}{2x} \right) = \frac{2x \cdot 2x - (x^2 - 1) \cdot 2}{4x^2} = \frac{2x^2 + 2}{4x^2} = \frac{x^2 + 1}{2x^2}; \text{ and} \\ f''(x) &= \frac{d}{dx} \left[\frac{x^2 + 1}{2x^2} \right] = \frac{2x^2 \cdot 2x - (x^2 + 1) \cdot 4x}{4x^4} = -\frac{4x}{4x^4} = -\frac{1}{x^3}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is never equal to 0 and does not exist when $x = 0$. However, 0 is not in the domain of f , so 0 is not a critical number. Therefore, f has **no critical numbers**.

Step 4 To apply the Increasing/Decreasing Function Test, use the number 0 to divide the number line into two intervals.

Interval	Sign of f'	Conclusion
$(-\infty, 0)$	+	f is increasing on $(-\infty, 0)$
$(0, \infty)$	+	f is increasing on $(0, \infty)$

Step 5 Because there are no critical numbers, f has **no local extreme values**.

Step 6 The second derivative is never equal to zero and does not exist when $x = 0$. Use this number to divide the number line into two intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, 0)$	+	f is concave up on $(-\infty, 0)$
$(0, \infty)$	-	f is concave down on $(0, \infty)$

Although the concavity of f changes at 0, there is **no point of inflection** at 0 because 0 is not in the domain of f .

Step 7 The figure below displays the graph of f .

13. Let $f(x) = \frac{x^4 + 1}{x^2}$.

Step 1 The domain of the rational function f is the set $\{x|x \neq 0\}$. There are no x -intercepts because $x^4 + 1$ is never equal to zero for any real x , and there is no y -intercept because f is not defined at 0.

Step 2 The degree of the numerator is two more than the degree of the denominator, so the graph of f has no horizontal asymptote, but the end behavior of the graph of f will resemble the power function $y = x^2$. To identify vertical asymptotes, check the one-sided limits at those values for x that are not in the domain of f . As

$$\lim_{x \rightarrow 0^-} \frac{x^4 + 1}{x^2} = \infty \quad \text{and} \quad \lim_{x \rightarrow 0^+} \frac{x^4 + 1}{x^2} = \infty,$$

the line $x = 0$ is a vertical asymptote.

Step 3 Now

$$\begin{aligned} f'(x) &= \frac{d}{dx} \left(\frac{x^4 + 1}{x^2} \right) = \frac{x^2 \cdot 4x^3 - (x^4 + 1) \cdot 2x}{x^4} = \frac{2x^5 - 2x}{x^4} = \frac{2(x^4 - 1)}{x^3} \\ &= \frac{2(x-1)(x+1)(x^2+1)}{x^3}; \text{ and} \\ f''(x) &= \frac{d}{dx} \left[\frac{2(x^4 - 1)}{x^3} \right] = \frac{x^3 \cdot 8x^3 - 2(x^4 - 1) \cdot 3x^2}{x^6} = \frac{2x^6 + 6x^2}{x^6} = \frac{2x^4 + 6}{x^4}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is equal to 0 when $x = \pm 1$ and does not exist when $x = 0$. However, 0 is not in the domain of f , so 0 is not a critical number. Therefore, ± 1 are the only critical numbers of f . At the points $(-1, 2)$ and $(1, 2)$, the tangent lines are horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the numbers 0 and ± 1 to divide the number line into four intervals.

Interval	Sign of f'	Conclusion
$(-\infty, -1)$	–	f is decreasing on $(-\infty, -1)$
$(-1, 0)$	+	f is increasing on $(-1, 0)$
$(0, 1)$	–	f is decreasing on $(0, 1)$
$(1, \infty)$	+	f is increasing on $(1, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local minimum value at -1 and a local minimum value at 1. The local minimum values are $f(-1) = 2$ and $f(1) = 2$.

Step 6 The second derivative is never equal to zero and does not exist when $x = 0$. Use this number to divide the number line into two intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, 0)$	+	f is concave up on $(-\infty, 0)$
$(0, \infty)$	+	f is concave up on $(0, \infty)$

Because the concavity of f does not change, f has no points of inflection.

Step 7 The figure below displays the graph of f . The local extreme values are highlighted by closed circles.

14. Let $f(x) = \frac{x^3 + 1}{x + 1} = \frac{(x + 1)(x^2 - x + 1)}{x + 1} = x^2 - x + 1$ for $x \neq -1$.

Step 1 The domain of the rational function f is the set $\{x | x \neq -1\}$. There are no x -intercepts because

$$x^2 - x + 1 = \left(x - \frac{1}{2}\right)^2 + \frac{3}{4}$$

is never equal to zero for any real x , and the y -intercept is $f(0) = 1$.

Step 2 The degree of the numerator is two more than the degree of the denominator, so the graph of f has no horizontal asymptote, but the end behavior of the graph of f will resemble the power function $y = x^2$. To identify vertical asymptotes, check the limit at those values for x that are not in the domain of f . As

$$\lim_{x \rightarrow -1} \frac{x^3 + 1}{x + 1} = \lim_{x \rightarrow -1} \frac{(x + 1)(x^2 - x + 1)}{x + 1} = \lim_{x \rightarrow -1} (x^2 - x + 1) = 3,$$

the graph of f does not have a vertical asymptote at $x = -1$, but does have a missing point at $(-1, 3)$.

Step 3 Now, for $x \neq -1$

$$\begin{aligned} f'(x) &= \frac{d}{dx} (x^2 - x + 1) = 2x - 1; \text{ and} \\ f''(x) &= \frac{d}{dx} [2x - 1] = 2. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is equal to 0 when $x = \frac{1}{2}$ and does not exist when $x = -1$. However, -1 is not in the domain of f , so -1 is

not a critical number. Therefore, $\frac{1}{2}$ is the only critical number of f . At the point $\left(\frac{1}{2}, \frac{3}{4}\right)$, the tangent line is horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the numbers -1 and $\frac{1}{2}$ to divide the number line into three intervals.

Interval	Sign of f'	Conclusion
$(-\infty, -1)$	$-$	f is decreasing on $(-\infty, -1)$
$(-1, \frac{1}{2})$	$-$	f is decreasing on $(-1, \frac{1}{2})$
$(\frac{1}{2}, \infty)$	$+$	f is increasing on $(\frac{1}{2}, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local minimum value at $\frac{1}{2}$. The local minimum value is $f\left(\frac{1}{2}\right) = \frac{3}{4}$.

Step 6 The second derivative is never equal to zero and does not exist when $x = -1$. Use this number to divide the number line into two intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, -1)$	+	f is concave up on $(-\infty, -1)$
$(-1, \infty)$	+	f is concave up on $(-1, \infty)$

Because the concavity of f does not change, f has no points of inflection.

Step 7 The figure below displays the graph of f . The local extreme value is highlighted by a closed circle.

15. Let $xy = x^2 + 2$, so that $y = f(x) = \frac{x^2 + 2}{x}$.

Step 1 The domain of the rational function f is the set $\{x|x \neq 0\}$. There are no x -intercepts because $x^2 + 2$ is never equal to zero for any real x , and there is no y -intercept because f is not defined at 0.

Step 2 The degree of the numerator is one more than the degree of the denominator, so the graph of f has no horizontal asymptote but does have an oblique asymptote. Because

$$f(x) = \frac{x^2 + 2}{x} = x + \frac{2}{x},$$

it follows that

$$\lim_{x \rightarrow \infty} [f(x) - x] = \lim_{x \rightarrow \infty} \frac{2}{x} = 0$$

so the line $y = x$ is an oblique asymptote. To identify vertical asymptotes, check the one-sided limits at those values for x that are not in the domain of f . As

$$\lim_{x \rightarrow 0^-} \frac{x^2 + 2}{x} = -\infty \quad \text{and} \quad \lim_{x \rightarrow 0^+} \frac{x^2 + 2}{x} = \infty,$$

the line $x = 0$ is a vertical asymptote.

Step 3 Now

$$\begin{aligned} f'(x) &= \frac{d}{dx} \left(\frac{x^2 + 2}{x} \right) = \frac{x \cdot 2x - (x^2 + 2) \cdot 1}{x^2} = \frac{x^2 - 2}{x^2}; \text{ and} \\ f''(x) &= \frac{d}{dx} \left[\frac{x^2 - 2}{x^2} \right] = \frac{x^2 \cdot 2x - (x^2 - 2) \cdot 2x}{x^4} = \frac{4x}{x^4} = \frac{4}{x^3}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is equal to 0 when $x = \pm\sqrt{2}$ and does not exist when $x = 0$. However, 0 is not in the domain of f , so 0 is not a critical number. Therefore, $\pm\sqrt{2}$ are the only critical numbers of f . At the points $(-\sqrt{2}, -2\sqrt{2})$ and $(\sqrt{2}, 2\sqrt{2})$, the tangent lines are horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the numbers 0 and $\pm\sqrt{2}$ to divide the number line into four intervals.

Interval	Sign of f'	Conclusion
$(-\infty, -\sqrt{2})$	+	f is increasing on $(-\infty, -\sqrt{2})$
$(-\sqrt{2}, 0)$	-	f is decreasing on $(-\sqrt{2}, 0)$
$(0, \sqrt{2})$	-	f is decreasing on $(0, \sqrt{2})$
$(\sqrt{2}, \infty)$	+	f is increasing on $(\sqrt{2}, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local maximum value at $-\sqrt{2}$ and a local minimum value at $\sqrt{2}$. The local maximum value is $f(-\sqrt{2}) = -2\sqrt{2}$, and the local minimum value is $f(\sqrt{2}) = 2\sqrt{2}$.

Step 6 The second derivative is never equal to zero and does not exist when $x = 0$. Use this number to divide the number line into two intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, 0)$	-	f is concave down on $(-\infty, 0)$
$(0, \infty)$	+	f is concave up on $(0, \infty)$

Although the concavity of f changes at 0, there is no point of inflection at 0 because 0 is not in the domain of f .

Step 7 The figure below displays the graph of f . The local extreme values are highlighted by closed circles.

16. Let $xy = x^2 + x - 1$, so that $y = f(x) = \frac{x^2 + x - 1}{x}$.

Step 1 The domain of the rational function f is the set $\{x|x \neq 0\}$. The x -intercepts are the solutions of the equation $x^2 + x - 1 = 0$. By the quadratic formula

$$x = \frac{-1 \pm \sqrt{1^2 - 4(1)(-1)}}{2} = \frac{-1 \pm \sqrt{5}}{2},$$

so the x -intercepts are $\frac{-1 \pm \sqrt{5}}{2}$. There is **no y -intercept** because f is not defined at 0.

Step 2 The degree of the numerator is one more than the degree of the denominator, so the graph of f has no horizontal asymptote but does have an oblique asymptote. Because

$$f(x) = \frac{x^2 + x - 1}{x} = x + 1 - \frac{1}{x},$$

it follows that

$$\lim_{x \rightarrow \infty} [f(x) - (x + 1)] = \lim_{x \rightarrow \infty} \left(-\frac{1}{x} \right) = 0$$

so the line **$y = x + 1$ is an oblique asymptote**. To identify vertical asymptotes, check the one-sided limits at those values for x that are not in the domain of f . As

$$\lim_{x \rightarrow 0^-} \frac{x^2 + x - 1}{x} = \infty \quad \text{and} \quad \lim_{x \rightarrow 0^+} \frac{x^2 + x - 1}{x} = -\infty,$$

the line **$x = 0$ is a vertical asymptote**.

Step 3 Now

$$\begin{aligned} f'(x) &= \frac{d}{dx} \left(\frac{x^2 + x - 1}{x} \right) = \frac{x \cdot (2x + 1) - (x^2 + x - 1) \cdot 1}{x^2} = \frac{x^2 + 1}{x^2}; \text{ and} \\ f''(x) &= \frac{d}{dx} \left[\frac{x^2 + 1}{x^2} \right] = \frac{x^2 \cdot 2x - (x^2 + 1) \cdot 2x}{x^4} = -\frac{2x}{x^4} = -\frac{2}{x^3}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is never equal to 0 and does not exist when $x = 0$. However, 0 is not in the domain of f , so 0 is not a critical number. Therefore, f has **no critical numbers**.

Step 4 To apply the Increasing/Decreasing Function Test, use the number 0 to divide the number line into two intervals.

Interval	Sign of f'	Conclusion
$(-\infty, 0)$	+	f is increasing on $(-\infty, 0)$
$(0, \infty)$	+	f is increasing on $(0, \infty)$

Step 5 Because there are no critical numbers, f has **no local extreme values**.

Step 6 The second derivative is never equal to zero and does not exist when $x = 0$. Use this number to divide the number line into two intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, 0)$	+	f is concave up on $(-\infty, 0)$
$(0, \infty)$	-	f is concave down on $(0, \infty)$

Although the concavity of f changes at 0, there is **no point of inflection** at 0 because 0 is not in the domain of f .

Step 7 The figure below displays the graph of f .

17. Let $f(x) = \frac{x^2}{x+3}$.

Step 1 The domain of the rational function f is the set $\{x|x \neq -3\}$. The x -intercept is 0, and the y -intercept is $f(0) = 0$.

Step 2 The degree of the numerator is one more than the degree of the denominator, so the graph of f has no horizontal asymptote but does have an oblique asymptote. Because

$$f(x) = \frac{x^2}{x+3} = x - 3 + \frac{9}{x+3},$$

it follows that

$$\lim_{x \rightarrow \infty} [f(x) - (x - 3)] = \lim_{x \rightarrow \infty} \frac{9}{x+3} = 0$$

so the line $y = x - 3$ is an oblique asymptote. To identify vertical asymptotes, check the one-sided limits at those values for x that are not in the domain of f . As

$$\lim_{x \rightarrow -3^-} \frac{x^2}{x+3} = -\infty \quad \text{and} \quad \lim_{x \rightarrow -3^+} \frac{x^2}{x+3} = \infty,$$

the line $x = -3$ is a vertical asymptote.

Step 3 Now

$$\begin{aligned} f'(x) &= \frac{d}{dx} \left(\frac{x^2}{x+3} \right) = \frac{(x+3) \cdot 2x - x^2 \cdot 1}{(x+3)^2} = \frac{x^2 + 6x}{(x+3)^2} = \frac{x(x+6)}{(x+3)^2}; \text{ and} \\ f''(x) &= \frac{d}{dx} \left[\frac{x^2 + 6x}{(x+3)^2} \right] = \frac{(x+3)^2 \cdot (2x+6) - (x^2 + 6x) \cdot 2(x+3)}{(x+3)^4} \\ &= \frac{2(x+3)^2 - 2(x^2 + 6x)}{(x+3)^3} = \frac{18}{(x+3)^3}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is equal to 0 when $x = 0$ and $x = -6$ and does not exist when $x = -3$. However, -3 is not in the domain of f , so -3 is not a critical number. Therefore, -6 and 0 are the only critical numbers of f . At the points $(-6, -12)$ and $(0, 0)$, the tangent lines are horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the numbers -6 , -3 , and 0 to divide the number line into four intervals.

Interval	Sign of f'	Conclusion
$(-\infty, -6)$	+	f is increasing on $(-\infty, -6)$
$(-6, -3)$	-	f is decreasing on $(-6, -3)$
$(-3, 0)$	-	f is decreasing on $(-3, 0)$
$(0, \infty)$	+	f is increasing on $(0, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local maximum value at -6 and a local minimum value at 0 . The $\boxed{\text{local maximum value is } f(-6) = -12}$, and the $\boxed{\text{local minimum value is } f(0) = 0}$.

Step 6 The second derivative is never equal to zero and does not exist when $x = -3$. Use this number to divide the number line into two intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, -3)$	-	f is concave down on $(-\infty, -3)$
$(-3, \infty)$	+	f is concave up on $(-3, \infty)$

Although the concavity of f changes at -3 , there is $\boxed{\text{no point of inflection}}$ at -3 because -3 is not in the domain of f .

Step 7 The figure below displays the graph of f . The local extreme values are highlighted by closed circles.

18. Let $f(x) = \frac{3x^2 - 1}{x - 1}$.

Step 1 The domain of the rational function f is the set $\boxed{\{x|x \neq 1\}}$. The $\boxed{x\text{-intercepts are } \pm \frac{\sqrt{3}}{3}}$, and the $\boxed{y\text{-intercept is } f(0) = 1}$.

Step 2 The degree of the numerator is one more than the degree of the denominator, so the graph of f has no horizontal asymptote but does have an oblique asymptote. Because

$$f(x) = \frac{3x^2 - 1}{x - 1} = 3x + 3 + \frac{2}{x - 1},$$

it follows that

$$\lim_{x \rightarrow \infty} [f(x) - (3x + 3)] = \lim_{x \rightarrow \infty} \frac{2}{x - 1} = 0$$

so the line $y = 3x + 3$ is an oblique asymptote. To identify vertical asymptotes, check the one-sided limits at those values for x that are not in the domain of f . As

$$\lim_{x \rightarrow 1^-} \frac{3x^2 - 1}{x - 1} = -\infty \quad \text{and} \quad \lim_{x \rightarrow 1^+} \frac{3x^2 - 1}{x - 1} = \infty,$$

the line $x = 1$ is a vertical asymptote.

Step 3 Now

$$\begin{aligned} f'(x) &= \frac{d}{dx} \left(\frac{3x^2 - 1}{x - 1} \right) = \frac{(x - 1) \cdot 6x - (3x^2 - 1) \cdot 1}{(x - 1)^2} = \frac{3x^2 - 6x + 1}{(x - 1)^2}; \text{ and} \\ f''(x) &= \frac{d}{dx} \left[\frac{3x^2 - 6x + 1}{(x - 1)^2} \right] = \frac{(x - 1)^2 \cdot (6x - 6) - (3x^2 - 6x + 1) \cdot 2(x - 1)}{(x - 1)^4} \\ &= \frac{6(x - 1)^2 - 2(3x^2 - 6x + 1)}{(x - 1)^3} = \frac{4}{(x - 1)^3}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is equal to 0 when $3x^2 - 6x + 1 = 0$. By the quadratic formula,

$$x = \frac{6 \pm \sqrt{(-6)^2 - 4(3)(1)}}{6} = \frac{6 \pm \sqrt{24}}{6} = 1 \pm \frac{\sqrt{6}}{3},$$

so $1 \pm \frac{\sqrt{6}}{3}$ are critical numbers of f . Although f' does not exist at 1, 1 is not in the domain of f , so 1 is not a critical number. At the points

$$\left(1 - \frac{\sqrt{6}}{3}, 6 - 2\sqrt{6} \right) \quad \text{and} \quad \left(1 + \frac{\sqrt{6}}{3}, 6 + 2\sqrt{6} \right)$$

the tangent lines are horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the numbers 1 and $1 \pm \frac{\sqrt{6}}{3}$ to divide the number line into four intervals.

Interval	Sign of f'	Conclusion
$(-\infty, 1 - \frac{\sqrt{6}}{3})$	+	f is increasing on $(-\infty, 1 - \frac{\sqrt{6}}{3})$
$(1 - \frac{\sqrt{6}}{3}, 1)$	-	f is decreasing on $(1 - \frac{\sqrt{6}}{3}, 1)$
$(1, 1 + \frac{\sqrt{6}}{3})$	-	f is decreasing on $(1, 1 + \frac{\sqrt{6}}{3})$
$(1 + \frac{\sqrt{6}}{3}, \infty)$	+	f is increasing on $(1 + \frac{\sqrt{6}}{3}, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local maximum value at $1 - \frac{\sqrt{6}}{3}$ and a local minimum value at $1 + \frac{\sqrt{6}}{3}$. The

$$\text{local maximum value is } f\left(1 - \frac{\sqrt{6}}{3}\right) = 6 - 2\sqrt{6},$$

and the

$$\text{local minimum value is } f\left(1 + \frac{\sqrt{6}}{3}\right) = 6 + 2\sqrt{6}.$$

Step 6 The second derivative is never equal to zero and does not exist when $x = 1$. Use this number to divide the number line into two intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, 1)$	$-$	f is concave down on $(-\infty, 1)$
$(1, \infty)$	$+$	f is concave up on $(1, \infty)$

Although the concavity of f changes at 1, there is no point of inflection at 1 because 1 is not in the domain of f .

Step 7 The figure below displays the graph of f . The local extreme values are highlighted by closed circles.

19. Let $f(x) = 1 + \frac{1}{x} + \frac{1}{x^2} = \frac{x^2 + x + 1}{x^2}$.

Step 1 The domain of the rational function f is the set $\{x|x \neq 0\}$. There are no x -intercepts because

$x^2 + x + 1 = \left(x + \frac{1}{2}\right)^2 + \frac{3}{4}$ is never equal to zero for any real x , and there is no y -intercept because f is not defined at 0.

Step 2 The degree of the numerator is equal to the degree of the denominator, so the graph of f has a horizontal asymptote. Because

$$\lim_{x \rightarrow \pm\infty} \left(1 + \frac{1}{x} + \frac{1}{x^2}\right) = 1,$$

the line $y = 1$ is a horizontal asymptote. To identify vertical asymptotes, check the one-sided limits at those values for x that are not in the domain of f . As

$$\lim_{x \rightarrow 0^-} \frac{x^2 + x + 1}{x^2} = \infty \quad \text{and} \quad \lim_{x \rightarrow 0^+} \frac{x^2 + x + 1}{x^2} = \infty,$$

the line $x = 0$ is a vertical asymptote.

Step 3 Now

$$\begin{aligned} f'(x) &= \frac{d}{dx} \left(1 + \frac{1}{x} + \frac{1}{x^2}\right) = -\frac{1}{x^2} - \frac{2}{x^3} = -\frac{x+2}{x^3}; \text{ and} \\ f''(x) &= \frac{d}{dx} \left(-\frac{1}{x^2} - \frac{2}{x^3}\right) = \frac{2}{x^3} + \frac{6}{x^4} = \frac{2x+6}{x^4}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is equal to 0 when $x = -2$ and does not exist when $x = 0$. However, 0 is not in the domain of f , so 0 is not a critical number. Therefore, -2 is the only critical number of f . At the point $\left(-2, \frac{3}{4}\right)$, the tangent line is horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the numbers -2 and 0 to divide the number line into three intervals.

Interval	Sign of f'	Conclusion
$(-\infty, -2)$	$-$	f is decreasing on $(-\infty, -2)$
$(-2, 0)$	$+$	f is increasing on $(-2, 0)$
$(0, \infty)$	$-$	f is decreasing on $(0, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local minimum value at -2 . The local minimum value is $f(-2) = \frac{3}{4}$.

Step 6 The second derivative is equal to zero when $x = -3$ and does not exist when $x = 0$. Use these numbers to divide the number line into three intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, -3)$	$-$	f is concave down on $(-\infty, -3)$
$(-3, 0)$	$+$	f is concave up on $(-3, 0)$
$(0, \infty)$	$+$	f is concave up on $(0, \infty)$

The concavity of f changes at -3 so the point $\left(-3, \frac{7}{9}\right)$ is a point of inflection of f .

Step 7 The figure below displays the graph of f . The local extreme value is highlighted by a closed circle, and the point of inflection is highlighted by a closed square.

20. Let $f(x) = \frac{2}{x} + \frac{1}{x^2} = \frac{2x+1}{x^2}$.

Step 1 The domain of the rational function f is the set $\{x|x \neq 0\}$. The x -intercept is $-\frac{1}{2}$, and there is no y -intercept because f is not defined at 0 .

Step 2 The degree of the numerator is less than the degree of the denominator, so the graph of f has a horizontal asymptote. Because

$$\lim_{x \rightarrow \pm\infty} \left(\frac{2}{x} + \frac{1}{x^2} \right) = 0,$$

the line $y = 0$ is a horizontal asymptote. To identify vertical asymptotes, check the one-sided limits at those values for x that are not in the domain of f . As

$$\lim_{x \rightarrow 0^-} \frac{2x+1}{x^2} = \infty \quad \text{and} \quad \lim_{x \rightarrow 0^+} \frac{2x+1}{x^2} = \infty,$$

the line $x = 0$ is a vertical asymptote.

Step 3 Now

$$f'(x) = \frac{d}{dx} \left(\frac{2}{x} + \frac{1}{x^2} \right) = -\frac{2}{x^2} - \frac{2}{x^3} = -\frac{2x+2}{x^3}; \text{ and}$$

$$f''(x) = \frac{d}{dx} \left(-\frac{2}{x^2} - \frac{2}{x^3} \right) = \frac{4}{x^3} + \frac{6}{x^4} = \frac{4x+6}{x^4}.$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is equal to 0 when $x = -1$ and does not exist when $x = 0$. However, 0 is not in the domain of f , so 0 is not a critical number. Therefore, -1 is the only critical number of f . At the point $(-1, -1)$, the tangent line is horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the numbers -1 and 0 to divide the number line into three intervals.

Interval	Sign of f'	Conclusion
$(-\infty, -1)$	$-$	f is decreasing on $(-\infty, -1)$
$(-1, 0)$	$+$	f is increasing on $(-1, 0)$
$(0, \infty)$	$-$	f is decreasing on $(0, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local minimum value at -1 . The local minimum value is $f(-1) = -1$.

Step 6 The second derivative is equal to zero when $x = -\frac{3}{2}$ and does not exist when $x = 0$. Use these numbers to divide the number line into three intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, -\frac{3}{2})$	$-$	f is concave down on $(-\infty, -\frac{3}{2})$
$(-\frac{3}{2}, 0)$	$+$	f is concave up on $(-\frac{3}{2}, 0)$
$(0, \infty)$	$+$	f is concave up on $(0, \infty)$

The concavity of f changes at $-\frac{3}{2}$ so the point $(-\frac{3}{2}, -\frac{8}{9})$ is a point of inflection of f .

Step 7 The figure below displays the graph of f . The local extreme value is highlighted by a closed circle, and the point of inflection is highlighted by a closed square.

21. Let $f(x) = \sqrt{3-x}$.

Step 1 The domain of f is given by the solution to the inequality $3 - x \geq 0$; that is, the set $\{x|x \leq 3\}$.

The x -intercept is 3, and the y -intercept is $f(0) = \sqrt{3}$.

Step 2 Because

$$\lim_{x \rightarrow -\infty} \sqrt{3 - x} = \infty,$$

the graph of f does not have a horizontal asymptote. The graph also has no vertical asymptotes.

Step 3 Now,

$$\begin{aligned} f'(x) &= -\frac{1}{2}(3-x)^{-1/2} = -\frac{1}{2\sqrt{3-x}}; \text{ and} \\ f''(x) &= -\frac{1}{4}(3-x)^{-3/2} = -\frac{1}{4\sqrt{(3-x)^3}}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is never equal to 0 and does not exist when $x = 3$. Therefore, 3 is the only critical number of f . At the point $(3, 0)$, the tangent line is vertical.

Step 4 Because $f'(x) < 0$ for all $x < 3$, f is decreasing on the interval $(-\infty, 3)$.

Step 5 Because the only critical number of f is an endpoint of the domain of f , f has no local extreme values.

Step 6 Because $f''(x) < 0$ for all $x < 3$, f is concave down on the interval $(-\infty, 3)$. As the concavity of f never changes, f has no points of inflection.

Step 7 The figure below displays the graph of f .

22. Let $f(x) = x\sqrt{x+2}$.

Step 1 The domain of f is given by the solution to the inequality $x+2 \geq 0$; that is, the set $\{x|x \geq -2\}$.

The x -intercepts are -2 and 0 , and the y -intercept is $f(0) = 0$.

Step 2 Because

$$\lim_{x \rightarrow \infty} x\sqrt{x+2} = \infty,$$

the graph of f does not have a horizontal asymptote. The graph also has no vertical asymptotes.

Step 3 Now,

$$\begin{aligned} f'(x) &= \frac{d}{dx}(x\sqrt{x+2}) = x \cdot \frac{1}{2\sqrt{x+2}} + \sqrt{x+2} = \frac{3x+4}{2\sqrt{x+2}}; \text{ and} \\ f''(x) &= \frac{d}{dx}\left(\frac{3x+4}{2\sqrt{x+2}}\right) = \frac{2\sqrt{x+2} \cdot 3 - (3x+4) \cdot (x+2)^{-1/2}}{4(x+2)} \\ &= \frac{6(x+2) - (3x+4)}{4(x+2)^{3/2}} = \frac{3x+8}{4(x+2)^{3/2}}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is equal to 0 when $x = -\frac{4}{3}$ and does not exist when $x = -2$. Therefore, -2 and $-\frac{4}{3}$ are the critical numbers of f . At the point $(-2, 0)$, the tangent line is vertical; at the point $\left(-\frac{4}{3}, -\frac{4\sqrt{6}}{9}\right)$, the tangent line is horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the number $-\frac{4}{3}$ to divide $[-2, \infty)$ into two intervals.

Interval	Sign of f'	Conclusion
$(-2, -\frac{4}{3})$	$-$	f is decreasing on $(-2, -\frac{4}{3})$
$(-\frac{4}{3}, \infty)$	$+$	f is increasing on $(-\frac{4}{3}, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local minimum value at $-\frac{4}{3}$. The local minimum value is $f\left(-\frac{4}{3}\right) = -\frac{4\sqrt{6}}{9}$.

Step 6 Because $f''(x) > 0$ for all $x > -2$, f is concave up on the interval $(-2, \infty)$. As the concavity of f never changes, f has no points of inflection.

Step 7 The figure below displays the graph of f . The local extreme value is highlighted by a closed circle.

23. Let $f(x) = x + \sqrt{x}$.

Step 1 The domain of f is the set $\{x|x \geq 0\}$. The x -intercept is 0, and the y -intercept is $f(0) = 0$.

Step 2 Because

$$\lim_{x \rightarrow \infty} (x + \sqrt{x}) = \infty,$$

the graph of f does not have a horizontal asymptote. The graph also has no vertical asymptotes.

Step 3 Now,

$$\begin{aligned} f'(x) &= 1 + \frac{1}{2\sqrt{x}}; \text{ and} \\ f''(x) &= -\frac{1}{4x^{3/2}}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is never equal to 0 and does not exist when $x = 0$. Therefore, $\boxed{0}$ is the only critical number of f . At the point $(0, 0)$, the tangent line is vertical.

Step 4 Because $f'(x) > 1 > 0$ for all $x > 0$, f is increasing on the interval $(0, \infty)$.

Step 5 Because the only critical number of f is an endpoint of the domain of f , f has no local extreme values.

Step 6 Because $f''(x) < 0$ for all $x > 0$, f is concave down on the interval $(0, \infty)$. As the concavity of f never changes, f has no points of inflection.

Step 7 The figure below displays the graph of f .

24. Let $f(x) = \sqrt{x} - \sqrt{x+1}$.

Step 1 The domain of f is the set $\{x|x \geq 0\}$. There are no x -intercepts, and the y -intercept is $f(0) = -1$.

Step 2 Because

$$\lim_{x \rightarrow \infty} (\sqrt{x} - \sqrt{x+1}) = \lim_{x \rightarrow \infty} (\sqrt{x} - \sqrt{x+1}) \cdot \frac{\sqrt{x} + \sqrt{x+1}}{\sqrt{x} + \sqrt{x+1}} = \lim_{x \rightarrow \infty} \frac{-1}{\sqrt{x} + \sqrt{x+1}} = 0,$$

the line $y = 0$ is a horizontal asymptote. The graph of f has no vertical asymptotes.

Step 3 Now,

$$\begin{aligned} f'(x) &= \frac{1}{2\sqrt{x}} - \frac{1}{2\sqrt{x+1}}; \text{ and} \\ f''(x) &= -\frac{1}{4x^{3/2}} + \frac{1}{4(x+1)^{3/2}}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is never equal to 0 and does not exist when $x = -1$ and when $x = 0$. As -1 is not in the domain of f , -1 is not a critical number of f . Therefore, $\boxed{0}$ is the only critical number of f . At the point $(0, -1)$, the tangent line is vertical.

Step 4 Because $f'(x) > 0$ for all $x > 0$, f is increasing on the interval $(0, \infty)$.

Step 5 Because the only critical number of f is an endpoint of the domain of f , f has no local extreme values.

Step 6 Because $f''(x) < 0$ for all $x > 0$, f is concave down on the interval $(0, \infty)$. As the concavity of f never changes, f has no points of inflection.

Step 7 The figure below displays the graph of f .

25. Let $f(x) = \frac{x^2}{\sqrt{x+1}}$.

Step 1 The domain of f is given by the solution to the inequality $x+1 > 0$; that is, the set $\{x|x > -1\}$. The x -intercept is 0, and the y -intercept is $f(0) = 0$.

Step 2 Because

$$\lim_{x \rightarrow \infty} \frac{x^2}{\sqrt{x+1}} = \infty,$$

the graph of f does not have a horizontal asymptote. On the other hand,

$$\lim_{x \rightarrow -1^+} \frac{x^2}{\sqrt{x+1}} = \infty,$$

so the line $x = -1$ is a vertical asymptote.

Step 3 Now,

$$\begin{aligned} f'(x) &= \frac{d}{dx} \left(\frac{x^2}{\sqrt{x+1}} \right) = \frac{\sqrt{x+1} \cdot 2x - x^2 \cdot \frac{1}{2}(x+1)^{-1/2}}{x+1} \\ &= \frac{4x(x+1) - x^2}{2(x+1)^{3/2}} = \frac{3x^2 + 4x}{2(x+1)^{3/2}}; \text{ and} \\ f''(x) &= \frac{d}{dx} \left(\frac{3x^2 + 4x}{2(x+1)^{3/2}} \right) = \frac{2(x+1)^{3/2} \cdot (6x+4) - (3x^2 + 4x) \cdot 3(x+1)^{1/2}}{4(x+1)^3} \\ &= \frac{2(x+1)(6x+4) - 3(3x^2 + 4x)}{4(x+1)^{5/2}} = \frac{3x^2 + 8x + 8}{4(x+1)^{5/2}}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is equal to 0 when $x = 0$ and when $x = -\frac{4}{3}$ and does not exist when $x = -1$. As $-\frac{4}{3}$ and -1 are not in the

domain of f , $-\frac{4}{3}$ and -1 are not critical numbers of f . Therefore, $\boxed{0}$ is the only critical number of f . At the point $(0, 0)$, the tangent line is horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the number 0 to divide $(-1, \infty)$ into two intervals.

Interval	Sign of f'	Conclusion
$(-1, 0)$	$-$	f is decreasing on $(-1, 0)$
$(0, \infty)$	$+$	f is increasing on $(0, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local minimum value at 0. The $\boxed{\text{local minimum value is } f(0) = 0}$.

Step 6 Because $f''(x) > 0$ for all $x > -1$, f is $\boxed{\text{concave up on the interval } (-1, \infty)}$. As the concavity of f never changes, f has $\boxed{\text{no points of inflection}}$.

Step 7 The figure below displays the graph of f . The local extreme value is highlighted by a closed circle.

26. Let $f(x) = \frac{x}{\sqrt{x^2 + 2}}$.

Step 1 Because $x^2 + 2 \geq 2 > 0$ for all x , the domain of f is the set of $\boxed{\text{all real numbers}}$. The $\boxed{x\text{-intercept is } 0}$, and the $\boxed{y\text{-intercept is } f(0) = 0}$.

Step 2 Because

$$\lim_{x \rightarrow -\infty} \frac{x}{\sqrt{x^2 + 2}} = \lim_{x \rightarrow -\infty} \frac{x}{|x|\sqrt{1 + \frac{2}{x^2}}} = \lim_{x \rightarrow -\infty} \frac{-1}{\sqrt{1 + \frac{2}{x^2}}} = -1$$

and

$$\lim_{x \rightarrow \infty} \frac{x}{\sqrt{x^2 + 2}} = \lim_{x \rightarrow \infty} \frac{x}{|x|\sqrt{1 + \frac{2}{x^2}}} = \lim_{x \rightarrow \infty} \frac{1}{\sqrt{1 + \frac{2}{x^2}}} = 1,$$

the lines $\boxed{y = \pm 1}$ are horizontal asymptotes. Because f is defined for all real numbers, the graph of f $\boxed{\text{does not have any vertical asymptotes}}$.

Step 3 Now,

$$\begin{aligned} f'(x) &= \frac{d}{dx} \left(\frac{x}{\sqrt{x^2 + 2}} \right) = \frac{\sqrt{x^2 + 2} \cdot 1 - x \cdot \frac{1}{2}(x^2 + 2)^{-1/2}(2x)}{x^2 + 2} \\ &= \frac{x^2 + 2 - x^2}{(x^2 + 2)^{3/2}} = \frac{2}{(x^2 + 2)^{3/2}}; \text{ and} \\ f''(x) &= \frac{d}{dx} \left(\frac{2}{(x^2 + 2)^{3/2}} \right) = -3(x^2 + 2)^{-5/2}(2x) = -\frac{6x}{(x^2 + 2)^{5/2}}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is never equal to 0 and exists for all x , so f has no critical numbers.

Step 4 Because $f'(x) > 0$ for all x , f is increasing on the interval $(-\infty, \infty)$.

Step 5 Because there are no critical numbers, f has no local extreme values.

Step 6 The second derivative is equal to zero when $x = 0$ and exists for all x . Use the number 0 to divide the number line into two intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, 0)$	+	f is concave up on $(-\infty, 0)$
$(0, \infty)$	-	f is concave down on $(0, \infty)$

The concavity of f changes at 0 so the point $(0, 0)$ is a point of inflection of f .

Step 7 The figure below displays the graph of f . The point of inflection is highlighted by a closed square.

27. Let $f(x) = \frac{1}{(x+1)(x-2)} = \frac{1}{x^2 - x - 2}$.

Step 1 The domain of the rational function f is the set $\{x | x \neq -1, x \neq 2\}$. There are no x -intercepts, and the y -intercept is $f(0) = -\frac{1}{2}$.

Step 2 The degree of the numerator is less than the degree of the denominator, so the graph of f has a horizontal asymptote. Because

$$\lim_{x \rightarrow \pm\infty} \frac{1}{x^2 - x - 2} = \lim_{x \rightarrow \pm\infty} \frac{1}{x^2 - x - 2} \cdot \frac{\frac{1}{x^2}}{\frac{1}{x^2}} = \lim_{x \rightarrow \pm\infty} \frac{\frac{1}{x^2}}{1 - \frac{1}{x} - \frac{2}{x^2}} = 0,$$

the line $y = 0$ is a horizontal asymptote. To identify vertical asymptotes, check the one-sided limits at those values for x that are not in the domain of f . As

$$\lim_{x \rightarrow -1^-} \frac{1}{(x+1)(x-2)} = \infty \quad \text{and} \quad \lim_{x \rightarrow -1^+} \frac{1}{(x+1)(x-2)} = -\infty,$$

and

$$\lim_{x \rightarrow 2^-} \frac{1}{(x+1)(x-2)} = -\infty \quad \text{and} \quad \lim_{x \rightarrow 2^+} \frac{1}{(x+1)(x-2)} = \infty,$$

the lines $x = -1$ and $x = 2$ are vertical asymptotes.

Step 3 Now,

$$\begin{aligned} f'(x) &= \frac{d}{dx} \left(\frac{1}{x^2 - x - 2} \right) = -\frac{2x - 1}{(x^2 - x - 2)^2}; \text{ and} \\ f''(x) &= -\frac{d}{dx} \left(\frac{2x - 1}{(x^2 - x - 2)^2} \right) = -\frac{(x^2 - x - 2)^2 \cdot 2 - (2x - 1) \cdot 2(x^2 - x - 2)(2x - 1)}{(x^2 - x - 2)^4} \\ &= -\frac{2(x^2 - x - 2) - 2(4x^2 - 4x + 1)}{(x^2 - x - 2)^3} = \frac{6(x^2 - x + 1)}{(x^2 - x - 2)^3}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is equal to 0 when $x = \frac{1}{2}$ and does not exist when $x = -1$ and when $x = 2$. As -1 and 2 are not in the

domain of f , -1 and 2 are not critical numbers. Therefore, $\boxed{\frac{1}{2}}$ is the only critical number of f .

At the point $\left(\frac{1}{2}, -\frac{4}{9}\right)$, the tangent line is horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the numbers -1 , $\frac{1}{2}$, and 2 to divide the number line into four intervals.

Interval	Sign of f'	Conclusion
$(-\infty, -1)$	+	f is increasing on $(-\infty, -1)$
$(-1, \frac{1}{2})$	+	f is increasing on $(-1, \frac{1}{2})$
$(\frac{1}{2}, 2)$	−	f is decreasing on $(\frac{1}{2}, 2)$
$(2, \infty)$	−	f is decreasing on $(2, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local maximum value at $\frac{1}{2}$. The local maximum value is $f\left(\frac{1}{2}\right) = -\frac{4}{9}$.

Step 6 The second derivative is never equal to zero and does not exist for $x = -1$ and $x = 2$. Use these numbers to divide the number line into three intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, -1)$	+	f is concave up on $(-\infty, -1)$
$(-1, 2)$	−	f is concave down on $(-1, 2)$
$(2, \infty)$	+	f is concave up on $(2, \infty)$

Although the concavity of f changes at -1 and 2 , there is no point of inflection at either -1 or 2 because -1 and 2 are not in the domain of f .

Step 7 The figure below displays the graph of f . The local extreme value is highlighted by a closed circle.

28. Let $f(x) = \frac{1}{(x-1)(x+3)} = \frac{1}{x^2 + 2x - 3}$.

Step 1 The domain of the rational function f is the set $\{x|x \neq -3, x \neq 1\}$. There are no x -intercepts,

and the y -intercept is $f(0) = -\frac{1}{3}$.

Step 2 The degree of the numerator is less than the degree of the denominator, so the graph of f has a horizontal asymptote. Because

$$\lim_{x \rightarrow \pm\infty} \frac{1}{x^2 + 2x - 3} = \lim_{x \rightarrow \pm\infty} \frac{1}{x^2 + 2x - 3} \cdot \frac{\frac{1}{x^2}}{\frac{1}{x^2}} = \lim_{x \rightarrow \pm\infty} \frac{\frac{1}{x^2}}{1 + \frac{2}{x} - \frac{3}{x^2}} = 0,$$

the line $y = 0$ is a horizontal asymptote. To identify vertical asymptotes, check the one-sided limits at those values for x that are not in the domain of f . As

$$\lim_{x \rightarrow -3^-} \frac{1}{(x-1)(x+3)} = \infty \quad \text{and} \quad \lim_{x \rightarrow -3^+} \frac{1}{(x-1)(x+3)} = -\infty,$$

and

$$\lim_{x \rightarrow 1^-} \frac{1}{(x-1)(x+3)} = -\infty \quad \text{and} \quad \lim_{x \rightarrow 1^+} \frac{1}{(x-1)(x+3)} = \infty,$$

the lines $x = -3$ and $x = 1$ are vertical asymptotes.

Step 3 Now,

$$\begin{aligned} f'(x) &= \frac{d}{dx} \left(\frac{1}{x^2 + 2x - 3} \right) = -\frac{2x + 2}{(x^2 + 2x - 3)^2}; \text{ and} \\ f''(x) &= -\frac{d}{dx} \left(\frac{2x + 2}{(x^2 + 2x - 3)^2} \right) = -\frac{(x^2 + 2x - 3)^2 \cdot 2 - (2x + 2) \cdot 2(x^2 + 2x - 3)(2x + 2)}{(x^2 + 2x - 3)^4} \\ &= -\frac{2(x^2 + 2x - 3) - 2(4x^2 + 8x + 4)}{(x^2 + 2x - 3)^3} = \frac{2(3x^2 + 6x + 7)}{(x^2 + 2x - 3)^3}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is equal to 0 when $x = -1$ and does not exist when $x = -3$ and when $x = 1$. As -3 and 1 are not in the domain of f , -3 and 1 are not critical numbers. Therefore, -1 is the only critical number of f .

At the point $\left(-1, -\frac{1}{4}\right)$, the tangent line is horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the numbers -3 , -1 , and 1 to divide the number line into four intervals.

Interval	Sign of f'	Conclusion
$(-\infty, -3)$	+	f is increasing on $(-\infty, -3)$
$(-3, -1)$	+	f is increasing on $(-3, -1)$
$(-1, 1)$	-	f is decreasing on $(-1, 1)$
$(1, \infty)$	-	f is decreasing on $(1, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local maximum value at -1 . The local maximum value is $f(-1) = -\frac{1}{4}$.

Step 6 The second derivative is never equal to zero and does not exist for $x = -3$ and $x = 1$. Use these numbers to divide the number line into three intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, -3)$	+	f is concave up on $(-\infty, -3)$
$(-3, 1)$	-	f is concave down on $(-3, 1)$
$(1, \infty)$	+	f is concave up on $(1, \infty)$

Although the concavity of f changes at -3 and 1 , there is no point of inflection at either -3 or 1 because -3 and 1 are not in the domain of f .

Step 7 The figure below displays the graph of f . The local extreme value is highlighted by a closed circle.

29. Let $f(x) = x^{2/3} + 3x^{1/3} + 2$.

Step 1 The domain of f is the set of all real numbers. Solving

$$x^{2/3} + 3x^{1/3} + 2 = (x^{1/3} + 2)(x^{1/3} + 1) = 0,$$

yields -8 and -1 as the x -intercepts; the y -intercept is $f(0) = 2$.

Step 2 Because

$$\lim_{x \rightarrow \pm\infty} (x^{2/3} + 3x^{1/3} + 2) = \lim_{x \rightarrow \pm\infty} \left[x^{2/3} \left(1 + \frac{3}{x^{1/3}} + \frac{2}{x^{2/3}} \right) \right] = \infty,$$

the graph of f does not have a horizontal asymptote. The graph also has no vertical asymptotes because f is defined for all x .

Step 3 Now,

$$f'(x) = \frac{2}{3}x^{-1/3} + x^{-2/3} = \frac{2x^{1/3} + 3}{3x^{2/3}}; \text{ and}$$

$$f''(x) = -\frac{2}{9}x^{-4/3} - \frac{2}{3}x^{-5/3} = -\frac{2x^{1/3} + 6}{9x^{5/3}}.$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is equal to 0 when $x = -\frac{27}{8}$ and does not exist when $x = 0$. Therefore, $-\frac{27}{8}$ and 0 are critical numbers of f . At the point $\left(-\frac{27}{8}, -\frac{1}{4}\right)$, the tangent line is horizontal; at the point $(0, 2)$, the tangent line is vertical.

Step 4 To apply the Increasing/Decreasing Function Test, use the numbers $-\frac{27}{8}$ and 0 to divide the number line into three intervals.

Interval	Sign of f'	Conclusion
$(-\infty, -\frac{27}{8})$	−	f is decreasing on $(-\infty, -\frac{27}{8})$
$(-\frac{27}{8}, 0)$	+	f is increasing on $(-\frac{27}{8}, 0)$
$(0, \infty)$	+	f is increasing on $(0, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local minimum value at $-\frac{27}{8}$ and has neither a local maximum value nor a local minimum value at 0. The

$$\text{local minimum value is } f\left(-\frac{27}{8}\right) = -\frac{1}{4}.$$

Step 6 The second derivative is equal to zero when $x = -27$ and does not exist when $x = 0$. Use these numbers to divide the number line into three intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, -27)$	−	f is concave down on $(-\infty, -27)$
$(-27, 0)$	+	f is concave up on $(-27, 0)$
$(0, \infty)$	−	f is concave down on $(0, \infty)$

The concavity of f changes at -27 and 0, so the points $(-27, 2)$ and $(0, 2)$ are points of inflection of f .

Step 7 The figure below displays the graph of f . The local extreme value is highlighted by a closed circle, and the points of inflection are highlighted by closed squares.

30. Let $f(x) = x^{5/3} - 5x^{2/3}$.

Step 1 The domain of f is the set of all real numbers. Solving

$$x^{5/3} - 5x^{2/3} = x^{2/3}(x - 5) = 0,$$

yields 0 and 5 as the x -intercepts; the y -intercept is $f(0) = 0$.

Step 2 Because

$$\lim_{x \rightarrow \pm\infty} (x^{5/3} - 5x^{2/3}) = \lim_{x \rightarrow \pm\infty} \left[x^{5/3} \left(1 - \frac{5}{x} \right) \right] = \pm\infty,$$

the graph of f does not have a horizontal asymptote. The graph also has no vertical asymptotes because f is defined for all x .

Step 3 Now,

$$\begin{aligned} f'(x) &= \frac{5}{3}x^{2/3} - \frac{10}{3}x^{-1/3} = \frac{5(x-2)}{3x^{1/3}}; \text{ and} \\ f''(x) &= \frac{10}{9}x^{-1/3} + \frac{10}{9}x^{-4/3} = \frac{10(x+1)}{9x^{4/3}}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is equal to 0 when $x = 2$ and does not exist when $x = 0$. Therefore, 0 and 2 are critical numbers of f . At the point $(0, 0)$, the tangent line is vertical; at the point $(2, -3\sqrt[3]{4})$, the tangent line is horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the numbers 0 and 2 to divide the number line into three intervals.

Interval	Sign of f'	Conclusion
$(-\infty, 0)$	+	f is increasing on $(-\infty, 0)$
$(0, 2)$	−	f is decreasing on $(0, 2)$
$(2, \infty)$	+	f is increasing on $(2, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local maximum value at 0 and a local minimum value at 2. The local maximum value is $f(0) = 0$, and the

local minimum value is $f(2) = -3\sqrt[3]{4}$.

Step 6 The second derivative is equal to zero when $x = -1$ and does not exist when $x = 0$. Use these numbers to divide the number line into three intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, -1)$	−	f is concave down on $(-\infty, -1)$
$(-1, 0)$	+	f is concave up on $(-1, 0)$
$(0, \infty)$	+	f is concave up on $(0, \infty)$

The concavity of f changes at -1 , so the point $(-1, -6)$ is a point of inflection of f .

Step 7 The figure below displays the graph of f . The local extreme values are highlighted by closed circles, and the point of inflection is highlighted by a closed square.

31. Let $f(x) = \sin x - \cos x$. Note the function f is periodic with period 2π .

Step 1 The domain of f is the set of all real numbers. The x -intercepts satisfy the equation

$$\sin x - \cos x = 0 \quad \text{or} \quad \tan x = 1;$$

the solutions to this equation are $\frac{\pi}{4} + k\pi$ for any integer k . The y -intercept is $f(0) = -1$.

Step 2 The function f has no asymptotes.

Step 3 Now,

$$\begin{aligned} f'(x) &= \cos x + \sin x; \text{ and} \\ f''(x) &= -\sin x + \cos x. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$, which is where $\cos x = -\sin x$ or $\tan x = -1$. Therefore, the critical numbers of f are $\frac{3\pi}{4} + k\pi$ for any integer k . At the points $\left(\frac{3\pi}{4} + k\pi, (-1)^k\sqrt{2}\right)$, the tangent lines are horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, consider the intervals $\left(-\frac{\pi}{4}, \frac{3\pi}{4}\right)$ and $\left(\frac{3\pi}{4}, \frac{7\pi}{4}\right)$.

The increasing/decreasing pattern on these two intervals will repeat indefinitely in either direction in increments of the period 2π . The results are shown in the table below.

Interval	Sign of f'	Conclusion
$\left(-\frac{\pi}{4}, \frac{3\pi}{4}\right)$	+	f is increasing on $\left(-\frac{\pi}{4}, \frac{3\pi}{4}\right)$
$\left(\frac{3\pi}{4}, \frac{7\pi}{4}\right)$	-	f is decreasing on $\left(\frac{3\pi}{4}, \frac{7\pi}{4}\right)$

Therefore, f is

increasing on intervals of the form $\left(-\frac{\pi}{4} + 2k\pi, \frac{3\pi}{4} + 2k\pi\right)$

and is

decreasing on intervals of the form $\left(\frac{3\pi}{4} + 2k\pi, \frac{7\pi}{4} + 2k\pi\right)$

for any integer k .

Step 5 By the First Derivative Test and the information above, f has a local maximum value at $\frac{3\pi}{4} + 2k\pi$ and a local minimum value at $\frac{7\pi}{4} + 2k\pi$ for any integer k . The

$$\text{local maximum value is } f\left(\frac{3\pi}{4} + 2k\pi\right) = \sqrt{2},$$

and the

$$\text{local minimum value is } f\left(\frac{7\pi}{4} + 2k\pi\right) = -\sqrt{2}.$$

Step 6 The second derivative exists everywhere and is equal to zero when $\tan x = 1$, which is when $x = \frac{\pi}{4} + k\pi$ for any integer k . Consider the intervals $\left(-\frac{3\pi}{4}, \frac{\pi}{4}\right)$ and $\left(\frac{\pi}{4}, \frac{5\pi}{4}\right)$, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$\left(-\frac{3\pi}{4}, \frac{\pi}{4}\right)$	+	f is concave up on $\left(-\frac{3\pi}{4}, \frac{\pi}{4}\right)$
$\left(\frac{\pi}{4}, \frac{5\pi}{4}\right)$	-	f is concave down on $\left(\frac{\pi}{4}, \frac{5\pi}{4}\right)$

Taking into account the period of the function f , it follows that f is

$$\text{concave up on intervals of the form } \left(-\frac{3\pi}{4} + 2k\pi, \frac{\pi}{4} + 2k\pi\right)$$

and is

$$\text{concave down on intervals of the form } \left(\frac{\pi}{4} + 2k\pi, \frac{5\pi}{4} + 2k\pi\right)$$

for any integer k . The concavity of f changes at $\frac{\pi}{4} + k\pi$ for each integer k , so $\left(\frac{\pi}{4} + k\pi, 0\right)$ is a point of inflection for each integer k .

Step 7 The figure below displays the graph of f over the interval $[0, 2\pi]$. The local extreme values are highlighted by closed circles, and the points of inflection are highlighted by closed squares. The graph repeats indefinitely in either direction with period 2π .

32. Let $f(x) = \sin x + \tan x$. Note the function f is periodic with period 2π .

Step 1 The domain of f is the set $\left\{x \mid x \neq \frac{2k+1}{2}\pi \text{ for any integer } k\right\}$. The x -intercepts satisfy the equation

$$\sin x + \tan x = 0 \quad \text{or} \quad \sin x \left(1 + \frac{1}{\cos x}\right) = 0;$$

the solutions to this equation are $k\pi$ for any integer k . The y -intercept is $f(0) = 0$.

Step 2 The function f has no horizontal asymptote. Because

$$\lim_{x \rightarrow (2k+1)\pi/2^-} (\sin x + \tan x) = \infty, \quad \text{and} \quad \lim_{x \rightarrow (2k+1)\pi/2^+} (\sin x + \tan x) = -\infty,$$

the lines $x = \frac{2k+1}{2}\pi$ are vertical asymptotes for each integer k .

Step 3 Now,

$$\begin{aligned} f'(x) &= \cos x + \sec^2 x = \frac{\cos^3 x + 1}{\cos^2 x}; \text{ and} \\ f''(x) &= -\sin x + 2\sec^2 x \tan x = \frac{\sin x(2 - \cos^3 x)}{\cos^3 x}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is equal to zero when $\cos^3 x = -1$ or $x = (2k+1)\pi$ and does not exist when $\cos x = 0$ or $x = \frac{2k+1}{2}\pi$ where k is any integer. As $\frac{2k+1}{2}\pi$ is not in the domain of f for any integer k , $\frac{2k+1}{2}\pi$ is not a critical number for any integer k . Therefore, the critical numbers of f are $(2k+1)\pi$ for any integer k . At the points $((2k+1)\pi, 0)$, the tangent lines are horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, consider the intervals $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$, $\left(\frac{\pi}{2}, \pi\right)$, and $\left(\pi, \frac{3\pi}{2}\right)$. The increasing/decreasing pattern on these two intervals will repeat indefinitely in either direction in increments of the period 2π . The results are shown in the table below.

Interval	Sign of f'	Conclusion
$\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$	+	f is increasing on $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$
$\left(\frac{\pi}{2}, \pi\right)$	+	f is increasing on $\left(\frac{\pi}{2}, \pi\right)$
$\left(\pi, \frac{3\pi}{2}\right)$	+	f is increasing on $\left(\pi, \frac{3\pi}{2}\right)$

Therefore f is increasing on intervals of the form $\left(-\frac{\pi}{2} + k\pi, \frac{\pi}{2} + k\pi\right)$ for any integer k .

Step 5 By the First Derivative Test and the information above, f has neither a local maximum value nor a local minimum value at $(2k+1)\pi$ for any integer k . Therefore, f has no local extreme values.

Step 6 The second derivative is equal to zero when $x = k\pi$ and does not exist when $x = \frac{2k+1}{2}\pi$ for any integer k . Consider the intervals $\left(-\frac{\pi}{2}, 0\right)$, $\left(0, \frac{\pi}{2}\right)$, $\left(\frac{\pi}{2}, \pi\right)$, and $\left(\pi, \frac{3\pi}{2}\right)$, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$\left(-\frac{\pi}{2}, 0\right)$	-	f is concave down on $\left(-\frac{\pi}{2}, 0\right)$
$\left(0, \frac{\pi}{2}\right)$	+	f is concave up on $\left(0, \frac{\pi}{2}\right)$
$\left(\frac{\pi}{2}, \pi\right)$	-	f is concave down on $\left(\frac{\pi}{2}, \pi\right)$
$\left(\pi, \frac{3\pi}{2}\right)$	+	f is concave up on $\left(\pi, \frac{3\pi}{2}\right)$

Taking into account the period of the function f , it follows that f is

$$\text{concave up on intervals of the form } \left(k\pi, \frac{2k+1}{2}\pi\right)$$

and is

$$\text{concave down on intervals of the form } \left(\frac{2k+1}{2}\pi, (k+1)\pi\right)$$

for any integer k . The concavity of f changes at $k\pi$ for each integer k , so the points $(k\pi, 0)$ are points of inflection for each integer k . Although concavity changes at $\frac{2k+1}{2}\pi$ for each integer k , there is no point of inflection at $\frac{2k+1}{2}\pi$ for any integer k because $\frac{2k+1}{2}\pi$ is not in the domain of f for any integer k .

Step 7 The figure below displays the graph of f over the interval $\left[-\frac{\pi}{2}, \frac{3\pi}{2}\right]$. The points of inflection are highlighted by closed squares. The graph repeats indefinitely in either direction with period 2π .

33. Let $f(x) = \sin^2 x - \cos x$. Note the function f is periodic with period 2π .

Step 1 The domain of f is the set of all real numbers. The x -intercepts satisfy the equation

$$\sin^2 x - \cos x = 1 - \cos^2 x - \cos x = 0.$$

This equation is quadratic in form, so by the quadratic formula,

$$\cos x = \frac{1 \pm \sqrt{(-1)^2 - 4(-1)(1)}}{-2} = \frac{-1 \pm \sqrt{5}}{2}.$$

Now, $\frac{-1 - \sqrt{5}}{2} < -1$ and $-1 \leq \cos x \leq 1$, so the x -intercepts are

$$\cos^{-1}\left(\frac{-1 + \sqrt{5}}{2}\right) + 2k\pi \approx 0.905 + 2k\pi \quad \text{and} \quad 2\pi - \cos^{-1}\left(\frac{-1 + \sqrt{5}}{2}\right) + 2k\pi \approx 5.379 + 2k\pi$$

for any integer k . The y -intercept is $f(0) = -1$.

Step 2 The graph of the function f has no asymptotes.

Step 3 Now,

$$\begin{aligned} f'(x) &= 2 \sin x \cos x + \sin x = \sin x(2 \cos x + 1); \text{ and} \\ f''(x) &= -2 \sin^2 x + \cos x(2 \cos x + 1) = 2 \cos^2 x - 2 \sin^2 x + \cos x \\ &= 4 \cos^2 x + \cos x - 2. \end{aligned}$$

As f is differentiable everywhere, the critical numbers of f occur where $f'(x) = 0$; that is, where $\sin x = 0$ and $2 \cos x + 1 = 0$. Therefore, $k\pi$, $\frac{2\pi}{3} + 2k\pi$, and $\frac{4\pi}{3} + 2k\pi$ are the critical numbers of f for any integer k . At the points $(k\pi, (-1)^{k+1})$, $\left(\frac{2\pi}{3} + 2k\pi, \frac{5}{4}\right)$, and $\left(\frac{4\pi}{3} + 2k\pi, \frac{5}{4}\right)$, the tangent lines are horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, consider the intervals $\left(0, \frac{2\pi}{3}\right)$, $\left(\frac{2\pi}{3}, \pi\right)$, $\left(\pi, \frac{4\pi}{3}\right)$, and $\left(\frac{4\pi}{3}, 2\pi\right)$. The increasing/decreasing pattern on these two intervals will repeat indefinitely in either direction in increments of the period 2π . The results are shown in the table below.

Interval	Sign of f'	Conclusion
$\left(0, \frac{2\pi}{3}\right)$	+	f is increasing on $\left(0, \frac{2\pi}{3}\right)$
$\left(\frac{2\pi}{3}, \pi\right)$	-	f is decreasing on $\left(\frac{2\pi}{3}, \pi\right)$
$\left(\pi, \frac{4\pi}{3}\right)$	+	f is increasing on $\left(\pi, \frac{4\pi}{3}\right)$
$\left(\frac{4\pi}{3}, 2\pi\right)$	-	f is decreasing on $\left(\frac{4\pi}{3}, 2\pi\right)$

Therefore, f is

$$\text{increasing on intervals of the form } \left(2k\pi, \frac{2\pi}{3} + 2k\pi\right) \text{ and } \left((2k+1)\pi, \frac{4\pi}{3} + 2k\pi\right)$$

and is

$$\text{decreasing on intervals of the form } \left(\frac{2\pi}{3} + 2k\pi, (2k+1)\pi\right) \text{ and } \left(\frac{4\pi}{3} + 2k\pi, (2k+2)\pi\right)$$

for any integer k .

Step 5 By the First Derivative Test and the information above, f has a local maximum value at $\frac{2\pi}{3} + 2k\pi$ and at $\frac{4\pi}{3} + 2k\pi$ and a local minimum value at $k\pi$ for each integer k . The

$$\text{local maximum values are } f\left(\frac{2\pi}{3} + 2k\pi\right) = \frac{5}{4} \text{ and } f\left(\frac{4\pi}{3} + 2k\pi\right) = \frac{5}{4},$$

and the local minimum values are $f(k\pi) = (-1)^k$.

Step 6 The second derivative exists everywhere and is equal to zero when $4 \cos^2 x + \cos x - 2 = 0$. This equation is quadratic in form, so by the quadratic formula,

$$\cos x = \frac{-1 \pm \sqrt{1^2 - 4(4)(-2)}}{8} = \frac{-1 \pm \sqrt{33}}{8}.$$

Therefore, $f''(x) = 0$ when

$$x = \cos^{-1}\left(\frac{-1 - \sqrt{33}}{8}\right) + 2k\pi \approx 2.574 + 2k\pi, \quad x = 2\pi - \cos^{-1}\left(\frac{-1 - \sqrt{33}}{8}\right) + 2k\pi \approx 3.709 + 2k\pi,$$

$$x = \cos^{-1}\left(\frac{-1 + \sqrt{33}}{8}\right) + 2k\pi \approx 0.936 + 2k\pi, \quad x = 2\pi - \cos^{-1}\left(\frac{-1 + \sqrt{33}}{8}\right) + 2k\pi \approx 5.347 + 2k\pi.$$

Consider the approximate intervals $(0.936, 2.574)$, $(2.574, 3.709)$, $(3.709, 5.347)$, and $(5.347, 7.219)$, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(0.936, 2.574)$	—	f is concave down on $(0.936, 2.574)$
$(2.574, 3.709)$	+	f is concave up on $(2.574, 3.709)$
$(3.709, 5.347)$	—	f is concave down on $(3.709, 5.347)$
$(5.347, 7.219)$	+	f is concave up on $(5.347, 7.219)$

Taking into account the period of the function f , it follows that f is

concave down on intervals of the form $(0.936 + 2k\pi, 2.574 + 2k\pi)$ and $(3.709 + 2k\pi, 5.347 + 2k\pi)$

and is

concave up on intervals of the form $(2.574 + 2k\pi, 3.709 + 2k\pi)$ and $(5.347 + 2k\pi, 7.219 + 2k\pi)$

for any integer k . The concavity of f changes at $0.936 + 2k\pi$, $2.574 + 2k\pi$, $3.709 + 2k\pi$, and $5.347 + 2k\pi$ for each integer k , so the points

$(0.936 + 2k\pi, 0.055)$, $(2.574 + 2k\pi, 1.132)$, $(3.709 + 2k\pi, 1.132)$, and $(5.347 + 2k\pi, 0.055)$

are points of inflection of f for each integer k .

Step 7 The figure below displays the graph of f over the interval $[0, 2\pi]$. The local extreme values are highlighted by closed circles, and the points of inflection are highlighted by closed squares. The graph repeats indefinitely in either direction with period 2π .

34. Let $f(x) = \cos^2 x + \sin x$. Note the function f is periodic with period 2π .

Step 1 The domain of f is the set of all real numbers. The x -intercepts satisfy the equation

$$\cos^2 x + \sin x = 1 - \sin^2 x + \sin x = 0.$$

This equation is quadratic in form, so by the quadratic formula,

$$\sin x = \frac{-1 \pm \sqrt{1^2 - 4(-1)(1)}}{-2} = \frac{1 \pm \sqrt{5}}{2}.$$

Now, $\frac{1+\sqrt{5}}{2} > 1$ and $-1 \leq \sin x \leq 1$, so the x -intercepts are

$$\sin^{-1}\left(\frac{1-\sqrt{5}}{2}\right) + 2k\pi \approx -0.666 + 2k\pi \quad \text{and} \quad \pi - \sin^{-1}\left(\frac{1-\sqrt{5}}{2}\right) + 2k\pi \approx 3.808 + 2k\pi$$

for any integer k . The y -intercept is $f(0) = 1$.

Step 2 The graph of the function f has no asymptotes.

Step 3 Now,

$$\begin{aligned} f'(x) &= -2\sin x \cos x + \cos x = \cos x(1 - 2\sin x); \text{ and} \\ f''(x) &= -2\cos^2 x - \sin x(1 - 2\sin x) = -2\cos^2 x + 2\sin^2 x - \sin x \\ &= 4\sin^2 x - \sin x - 2. \end{aligned}$$

As f is differentiable everywhere, the critical numbers of f occur where $f'(x) = 0$; that is, where $\cos x = 0$ and $1 - 2\sin x = 0$. Therefore, $\frac{\pi}{6} + 2k\pi$, $\frac{2k+1}{2}\pi$, and $\frac{5\pi}{6} + 2k\pi$ are the critical numbers of f for any integer k . At the points $\left(\frac{\pi}{6} + 2k\pi, \frac{5}{4}\right)$, $\left(\frac{2k+1}{2}\pi, (-1)^k\right)$, and $\left(\frac{5\pi}{6} + 2k\pi, \frac{5}{4}\right)$, the tangent lines are horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, consider the intervals $\left(-\frac{\pi}{2}, \frac{\pi}{6}\right)$, $\left(\frac{\pi}{6}, \frac{\pi}{2}\right)$, $\left(\frac{\pi}{2}, \frac{5\pi}{6}\right)$, and $\left(\frac{5\pi}{6}, \frac{3\pi}{2}\right)$. The increasing/decreasing pattern on these two intervals will repeat indefinitely in either direction in increments of the period 2π . The results are shown in the table below.

Interval	Sign of f'	Conclusion
$\left(-\frac{\pi}{2}, \frac{\pi}{6}\right)$	+	f is increasing on $\left(-\frac{\pi}{2}, \frac{\pi}{6}\right)$
$\left(\frac{\pi}{6}, \frac{\pi}{2}\right)$	-	f is decreasing on $\left(\frac{\pi}{6}, \frac{\pi}{2}\right)$
$\left(\frac{\pi}{2}, \frac{5\pi}{6}\right)$	+	f is increasing on $\left(\frac{\pi}{2}, \frac{5\pi}{6}\right)$
$\left(\frac{5\pi}{6}, \frac{3\pi}{2}\right)$	-	f is decreasing on $\left(\frac{5\pi}{6}, \frac{3\pi}{2}\right)$

Therefore, f is

$$\text{increasing on intervals of the form } \left(-\frac{\pi}{2} + 2k\pi, \frac{\pi}{6} + 2k\pi\right) \text{ and } \left(\frac{\pi}{2} + 2k\pi, \frac{5\pi}{6} + 2k\pi\right)$$

and is

$$\text{decreasing on intervals of the form } \left(\frac{\pi}{6} + 2k\pi, \frac{\pi}{2} + 2k\pi\right) \text{ and } \left(\frac{5\pi}{6} + 2k\pi, \frac{3\pi}{2} + 2k\pi\right)$$

for any integer k .

Step 5 By the First Derivative Test and the information in the table above, f has a local maximum value at $\frac{\pi}{6} + 2k\pi$ and at $\frac{5\pi}{6} + 2k\pi$ and a local minimum value at $\frac{2k+1}{2}\pi$ for each integer k . The

$$\text{local maximum values are } f\left(\frac{\pi}{6} + 2k\pi\right) = \frac{5}{4} \text{ and } f\left(\frac{5\pi}{6} + 2k\pi\right) = \frac{5}{4},$$

$$\text{and the local minimum values are } f\left(\frac{2k+1}{2}\pi\right) = (-1)^k.$$

Step 6 The second derivative exists everywhere and is equal to zero when $4\sin^2 x - \sin x - 2 = 0$. This equation is quadratic in form, so by the quadratic formula,

$$\sin x = \frac{1 \pm \sqrt{(-1)^2 - 4(4)(-2)}}{8} = \frac{1 \pm \sqrt{33}}{8}.$$

Therefore, $f''(x) = 0$ when

$$x = \sin^{-1}\left(\frac{1 - \sqrt{33}}{8}\right) + 2k\pi \approx -0.635 + 2k\pi, \quad x = \pi - \sin^{-1}\left(\frac{1 - \sqrt{33}}{8}\right) + 2k\pi \approx 3.776 + 2k\pi,$$

$$x = \sin^{-1}\left(\frac{1 + \sqrt{33}}{8}\right) + 2k\pi \approx 1.003 + 2k\pi, \quad x = \pi - \sin^{-1}\left(\frac{1 + \sqrt{33}}{8}\right) + 2k\pi \approx 2.139 + 2k\pi.$$

Consider the intervals $(-0.635, 1.003)$, $(1.003, 2.139)$, $(2.139, 3.776)$, and $(3.776, 5.648)$, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-0.635, 1.003)$	−	f is concave down on $(-0.635, 1.003)$
$(1.003, 2.139)$	+	f is concave up on $(1.003, 2.139)$
$(2.139, 3.776)$	−	f is concave down on $(2.139, 3.776)$
$(3.776, 5.648)$	+	f is concave up on $(3.776, 5.648)$

Taking into account the period of the function f , it follows that f is

concave down on intervals of the form $(-0.635 + 2k\pi, 1.003 + 2k\pi)$ and $(2.139 + 2k\pi, 3.776 + 2k\pi)$

and is

concave up on intervals of the form $(1.003 + 2k\pi, 2.139 + 2k\pi)$ and $(3.776 + 2k\pi, 5.648 + 2k\pi)$

for any integer k . The concavity of f changes at $1.003 + 2k\pi$, $2.139 + 2k\pi$, $3.776 + 2k\pi$, and $5.648 + 2k\pi$ for each integer n , so the points

$(1.003 + 2k\pi, 1.132)$, $(2.139 + 2k\pi, 1.132)$, $(3.776 + 2k\pi, 0.055)$, and $(5.648 + 2k\pi, 0.055)$

are points of inflection of f for any integer k .

Step 7 The figure below displays the graph of f over the interval $[0, 2\pi]$. The local extreme values are highlighted by closed circles, and the points of inflection are highlighted by closed squares. The graph repeats indefinitely in either direction with period 2π .

35. Let $y = f(x) = \ln x - x$.

Step 1 The domain of f is the set $\{x|x > 0\}$. There are no x -intercepts as the graphs of $y = \ln x$ and $y = x$ never intersect, and there is also no y -intercept because the function is not defined at 0.

Step 2 Because

$$\lim_{x \rightarrow \infty} \ln x = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} x = \infty,$$

the expression $\ln x - x$ is an indeterminate form at ∞ of the type $\infty - \infty$. Rewrite

$$\ln x - x \quad \text{as} \quad x \left(\frac{\ln x}{x} - 1 \right).$$

Now, the expression $\frac{\ln x}{x}$ is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$; by L'Hôpital's Rule,

$$\lim_{x \rightarrow \infty} \frac{\ln x}{x} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx} \ln x}{\frac{d}{dx} x} = \lim_{x \rightarrow \infty} \frac{\frac{1}{x}}{1} = 0.$$

Therefore,

$$\lim_{x \rightarrow \infty} \left(\frac{\ln x}{x} - 1 \right) = -1 \quad \text{and} \quad \lim_{x \rightarrow \infty} (\ln x - x) = \lim_{x \rightarrow \infty} \left[x \left(\frac{\ln x}{x} - 1 \right) \right] = -\infty,$$

so the graph of f has no horizontal asymptote. On the other hand,

$$\lim_{x \rightarrow 0^+} (\ln x - x) = -\infty,$$

so the line $x = 0$ is a vertical asymptote.

Step 3 Now,

$$\begin{aligned} f'(x) &= \frac{1}{x} - 1 = \frac{1-x}{x}; \text{ and} \\ f''(x) &= -\frac{1}{x^2}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is equal to zero when $x = 1$ and does not exist when $x = 0$; however, 0 is not a critical number because 0 is not in the domain of f . Therefore, 1 is the only critical number. At the point $(1, -1)$, the tangent line is horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the number 1 to divide $(0, \infty)$ into two intervals.

Interval	Sign of f'	Conclusion
$(0, 1)$	+	f is increasing on $(0, 1)$
$(1, \infty)$	-	f is decreasing on $(1, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local maximum value at 1. The local maximum value is $f(1) = -1$.

Step 6 Because $f''(x) < 0$ for all $x > 0$, f is concave down on the interval $(0, \infty)$, so f has no points of inflection.

Step 7 The figure below displays the graph of f . The local extreme value is highlighted by a closed circle.

36. Let $y = f(x) = x \ln x$.

Step 1 The domain of f is the set $\{x|x > 0\}$. The x -intercept is 1, and there is no y -intercept because the function is not defined at 0.

Step 2 Because

$$\lim_{x \rightarrow \infty} (x \ln x) = \infty,$$

the graph of f has no horizontal asymptote. Additionally, by L'Hôpital's Rule,

$$\lim_{x \rightarrow 0^+} (x \ln x) = \lim_{x \rightarrow 0^+} \frac{\ln x}{x^{-1}} = \lim_{x \rightarrow 0^+} \frac{x^{-1}}{-x^{-2}} = \lim_{x \rightarrow 0^+} (-x) = 0,$$

so the graph also has no vertical asymptote.

Step 3 Now,

$$\begin{aligned} f'(x) &= x \cdot \frac{1}{x} + \ln x = 1 + \ln x; \text{ and} \\ f''(x) &= \frac{1}{x}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is equal to zero when $x = e^{-1} = \frac{1}{e}$ and exists everywhere on the domain of f . Therefore, $\frac{1}{e}$ is the only critical number. At the point $\left(\frac{1}{e}, -\frac{1}{e}\right)$, the tangent line is horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the number $\frac{1}{e}$ to divide $(0, \infty)$ into two intervals.

Interval	Sign of f'	Conclusion
$(0, \frac{1}{e})$	$-$	f is decreasing on $(0, \frac{1}{e})$
$(\frac{1}{e}, \infty)$	$+$	f is increasing on $(\frac{1}{e}, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local minimum value at $\frac{1}{e}$. The local minimum value is $f\left(\frac{1}{e}\right) = -\frac{1}{e}$.

Step 6 Because $f''(x) > 0$ for all $x > 0$, f is concave up on the interval $(0, \infty)$, so f has no points of inflection.

Step 7 The figure below displays the graph of f . The local extreme value is highlighted by a closed circle.

37. Let $f(x) = \ln(4 - x^2)$.

Step 1 The domain of f is given by the solution to the inequality $4 - x^2 > 0$; that is, the set $\{x \mid -2 < x < 2\}$.

The x -intercepts are $\pm\sqrt{3}$, and the y -intercept is $f(0) = \ln 4$.

Step 2 Because f is not defined as x becomes unbounded in either direction, the graph of f has no horizontal asymptote. As x approaches the endpoints of the domain

$$\lim_{x \rightarrow -2^+} \ln(4 - x^2) = -\infty \quad \text{and} \quad \lim_{x \rightarrow 2^-} \ln(4 - x^2) = -\infty,$$

so the lines $x = \pm 2$ are vertical asymptotes.

Step 3 Now,

$$\begin{aligned} f'(x) &= \frac{1}{4 - x^2} \cdot (-2x) = -\frac{2x}{4 - x^2}; \text{ and} \\ f''(x) &= \frac{d}{dx} \left(-\frac{2x}{4 - x^2} \right) = -\frac{(4 - x^2) \cdot 2 - 2x \cdot (-2x)}{(4 - x^2)^2} = -\frac{8 + 2x^2}{(4 - x^2)^2}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is equal to zero when $x = 0$ and exists everywhere on the domain of f . Therefore, 0 is the only critical number. At the point $(0, \ln 4)$, the tangent line is horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the number 0 to divide $(-2, 2)$ into two intervals.

Interval	Sign of f'	Conclusion
$(-2, 0)$	+	f is increasing on $(-2, 0)$
$(0, 2)$	-	f is decreasing on $(0, 2)$

Step 5 By the First Derivative Test and the information in the table above, f has a local maximum value at 0. The local maximum value is $f(0) = \ln 4$.

Step 6 Because $f''(x) < 0$ for all $-2 < x < 2$, f is concave down on the interval $(-2, 2)$, so f has no points of inflection.

Step 7 The figure below displays the graph of f . The local extreme value is highlighted by a closed circle.

38. Let $f(x) = \ln(x^2 + 2)$.

Step 1 The domain of f is the set of all real numbers because $x^2 + 2 \geq 2 > 0$ for all real x . There are no x -intercepts, and the y -intercept is $f(0) = \ln 2$.

Step 2 Because

$$\lim_{x \rightarrow \pm\infty} \ln(x^2 + 2) = \infty,$$

the graph of f has no horizontal asymptote. The graph also has no vertical asymptotes because f is defined for all real numbers.

Step 3 Now,

$$\begin{aligned} f'(x) &= \frac{1}{x^2 + 2} \cdot 2x = \frac{2x}{x^2 + 2}; \text{ and} \\ f''(x) &= \frac{d}{dx} \left(\frac{2x}{x^2 + 2} \right) = \frac{(x^2 + 2) \cdot 2 - 2x \cdot 2x}{(x^2 + 2)^2} = \frac{4 - 2x^2}{(x^2 + 2)^2}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is equal to zero when $x = 0$ and exists everywhere. Therefore, 0 is the only critical number. At the point $(0, \ln 2)$, the tangent line is horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the number 0 to divide the number line into two intervals.

Interval	Sign of f'	Conclusion
$(-\infty, 0)$	–	f is decreasing on $(-\infty, 0)$
$(0, \infty)$	+	f is increasing on $(0, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local minimum value at 0. The local minimum value is $f(0) = \ln 2$.

Step 6 The second derivative exists everywhere and is equal to zero when $x = \pm\sqrt{2}$. Use these numbers to divide the number line into three intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, -\sqrt{2})$	–	f is concave down on $(-\infty, -\sqrt{2})$
$(-\sqrt{2}, \sqrt{2})$	+	f is concave up on $(-\sqrt{2}, \sqrt{2})$
$(\sqrt{2}, \infty)$	–	f is concave down on $(\sqrt{2}, \infty)$

The concavity of f changes at $\pm\sqrt{2}$, so the points $(-\sqrt{2}, \ln 4)$ and $(\sqrt{2}, \ln 4)$ are points of inflection of f .

Step 7 The figure below displays the graph of f . The local extreme value is highlighted by a closed circle, and the points of inflection are highlighted by closed squares.

39. Let $f(x) = 3e^{3x}(5 - x)$.

Step 1 The domain of f is the set of all real numbers. The x -intercept is 5, and the y -intercept is $f(0) = 15$.

Step 2 Because the domain of f is the set of all real numbers, the graph of f has no vertical asymptotes. To determine if there is a horizontal asymptote, consider the limits at infinity:

$$\lim_{x \rightarrow -\infty} [3e^{3x}(5 - x)] = \lim_{x \rightarrow -\infty} \frac{3(5 - x)}{e^{-3x}} = \lim_{x \rightarrow -\infty} \frac{-3}{-3e^{-3x}} = 0$$

and

$$\lim_{x \rightarrow \infty} [3e^{3x}(5 - x)] = -\infty,$$

where L'Hôpital's Rule was used in the first limit. Therefore, the graph of f has the line $y = 0$ as a horizontal asymptote as $x \rightarrow -\infty$ and no horizontal asymptote as $x \rightarrow \infty$.

Step 3 Now,

$$\begin{aligned} f'(x) &= -3e^{3x} + 9e^{3x}(5 - x) = 3e^{3x}(14 - 3x); \text{ and} \\ f''(x) &= -9e^{3x} + 9e^{3x}(14 - 3x) = 9e^{3x}(13 - 3x). \end{aligned}$$

The function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$, which is when $x = \frac{14}{3}$. At the point $\left(\frac{14}{3}, e^{14}\right)$, the tangent line is horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the number $\frac{14}{3}$ to divide the number line into two intervals.

Interval	Sign of f'	Conclusion
$(-\infty, \frac{14}{3})$	+	f is increasing on $(-\infty, \frac{14}{3})$
$(\frac{14}{3}, \infty)$	-	f is decreasing on $(\frac{14}{3}, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local maximum value at $\frac{14}{3}$. The local maximum value is $f\left(\frac{14}{3}\right) = e^{14}$.

Step 6 The second derivative exists everywhere and is equal to zero when $x = \frac{13}{3}$. Use this number to divide the number line into two intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, \frac{13}{3})$	+	f is concave up on $(-\infty, \frac{13}{3})$
$(\frac{13}{3}, \infty)$	-	f is concave down on $(\frac{13}{3}, \infty)$

The concavity of f changes at $\frac{13}{3}$, so the point $\left(\frac{13}{3}, 2e^{13}\right)$ is a point of inflection of f .

Step 7 The figure below displays the graph of f . The local extreme value is highlighted by a closed circle, and the point of inflection is highlighted by a closed square.

40. Let $f(x) = 3e^{-3x}(x - 4)$.

Step 1 The domain of f is the set of all real numbers. The x -intercept is 4, and the y -intercept is $f(0) = -12$.

Step 2 Because the domain of f is the set of all real numbers, the graph of f has no vertical asymptotes. To determine if there is a horizontal asymptote, consider the limits at infinity:

$$\lim_{x \rightarrow -\infty} [3e^{-3x}(x - 4)] = -\infty$$

and

$$\lim_{x \rightarrow \infty} [3e^{-3x}(x - 4)] = \lim_{x \rightarrow \infty} \frac{3(x - 4)}{e^{3x}} = \lim_{x \rightarrow \infty} \frac{3}{3e^{3x}} = 0$$

where L'Hôpital's Rule was used in the second limit. Therefore, the graph of f has the line $y = 0$ as a horizontal asymptote as $x \rightarrow \infty$ and no horizontal asymptote as $x \rightarrow -\infty$.

Step 3 Now,

$$\begin{aligned} f'(x) &= 3e^{-3x} - 9e^{-3x}(x - 4) = 3e^{-3x}(13 - 3x); \text{ and} \\ f''(x) &= -9e^{-3x} - 9e^{-3x}(13 - 3x) = -9e^{-3x}(14 - 3x). \end{aligned}$$

The function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$, which is when $x = \frac{13}{3}$. At the point $\left(\frac{13}{3}, e^{-13}\right)$, the tangent line is horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the number $\frac{13}{3}$ to divide the number line into two intervals.

Interval	Sign of f'	Conclusion
$(-\infty, \frac{13}{3})$	+	f is increasing on $(-\infty, \frac{13}{3})$
$(\frac{13}{3}, \infty)$	-	f is decreasing on $(\frac{13}{3}, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local maximum value at $\frac{13}{3}$. The local maximum value is $f\left(\frac{13}{3}\right) = e^{-13}$.

Step 6 The second derivative exists everywhere and is equal to zero when $x = \frac{14}{3}$. Use this number to divide the number line into two intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, \frac{14}{3})$	-	f is concave down on $(-\infty, \frac{14}{3})$
$(\frac{14}{3}, \infty)$	+	f is concave up on $(\frac{14}{3}, \infty)$

The concavity of f changes at $\frac{14}{3}$, so the point $\left(\frac{14}{3}, 2e^{-14}\right)$ is a point of inflection of f .

Step 7 The figures below display the graph of f . In the figure on the left, the x range is $0 \leq x \leq 5$. The figure on the right zooms in on the x range of $3.9 \leq x \leq 6$; the local extreme value is highlighted by a closed circle, and the point of inflection is highlighted by a closed square.

41. Let $f(x) = e^{-x^2}$.

Step 1 The domain of f is the set of all real numbers. There is no x -intercept, and the y -intercept is $f(0) = 1$.

Step 2 Because

$$\lim_{x \rightarrow \pm\infty} e^{-x^2} = 0,$$

the line $y = 0$ is a horizontal asymptote. The graph of f has no vertical asymptotes because f is defined for all real x .

Step 3 Now,

$$\begin{aligned} f'(x) &= -2xe^{-x^2}; \text{ and} \\ f''(x) &= 4x^2e^{-x^2} - 2e^{-x^2} = 2(2x^2 - 1)e^{-x^2}. \end{aligned}$$

The function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$, which is when $x = 0$. At the point $(0, 1)$, the tangent line is horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the number 0 to divide the number line into two intervals.

Interval	Sign of f'	Conclusion
$(-\infty, 0)$	+	f is increasing on $(-\infty, 0)$
$(0, \infty)$	-	f is decreasing on $(0, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local maximum value at 0. The local maximum value is $f(0) = 1$.

Step 6 The second derivative exists everywhere and is equal to zero when $x = \pm \frac{\sqrt{2}}{2}$. Use these numbers to divide the number line into three intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, -\frac{\sqrt{2}}{2})$	+	f is concave up on $(-\infty, -\frac{\sqrt{2}}{2})$
$(-\frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2})$	-	f is concave down on $(-\frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2})$
$(\frac{\sqrt{2}}{2}, \infty)$	+	f is concave up on $(\frac{\sqrt{2}}{2}, \infty)$

The concavity of f changes at $\pm \frac{\sqrt{2}}{2}$, so the points $\left(-\frac{\sqrt{2}}{2}, e^{-1/2}\right)$ and $\left(\frac{\sqrt{2}}{2}, e^{-1/2}\right)$ are points of inflection of f .

Step 7 The figure below displays the graph of f . The local extreme value is highlighted by a closed circle, and the points of inflection are highlighted by closed squares.

42. Let $f(x) = e^{1/x}$.

Step 1 The domain of f is the set $\{x|x \neq 0\}$. There are no x -intercepts, and there is also no y -intercept because the function is not defined at 0.

Step 2 Because

$$\lim_{x \rightarrow \pm\infty} e^{1/x} = 1,$$

the line $y = 1$ is a horizontal asymptote. To identify vertical asymptotes, check the one-sided limits at those values for x that are not in the domain of f . As

$$\lim_{x \rightarrow 0^-} e^{1/x} = 0 \quad \text{and} \quad \lim_{x \rightarrow 0^+} e^{1/x} = \infty,$$

the line $x = 0$ is a vertical asymptote.

Step 3 Now,

$$\begin{aligned}f'(x) &= -\frac{1}{x^2}e^{1/x}; \text{ and} \\f''(x) &= \frac{1}{x^4}e^{1/x} + \frac{2}{x^3}e^{1/x} = \frac{1}{x^4}e^{1/x}(1 + 2x).\end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is never equal to zero and does not exist when $x = 0$. However, 0 is not in the domain of f , so 0 is not a critical number. Therefore, f has no critical numbers.

Step 4 Because $f'(x) < 0$ for all $x \neq 0$, f is decreasing on the intervals $(-\infty, 0)$ and $(0, \infty)$.

Step 5 Because there are no critical numbers, f has no local extreme values.

Step 6 The second derivative is equal to zero when $x = -\frac{1}{2}$ and does not exist when $x = 0$. Use these numbers to divide the number line into three intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, -\frac{1}{2})$	–	f is concave down on $(-\infty, -\frac{1}{2})$
$(-\frac{1}{2}, 0)$	+	f is concave up on $(-\frac{1}{2}, 0)$
$(0, \infty)$	+	f is concave up on $(0, \infty)$

The concavity of f changes at $-\frac{1}{2}$, so the point $(-\frac{1}{2}, \frac{1}{e^2})$ is a point of inflection of f .

Step 7 The figure below displays the graph of f . The point of inflection is highlighted by a closed square.

Applications and Extensions

43. Let $f(x) = \frac{x^{2/3}}{x-1}$.

- (a) The figures below display the graph of f . In the top figure, the graph is shown for $-20 \leq x \leq 10$. In the figure at the bottom left, attention is focused on $-10 \leq x \leq 0$. Attention is focused on $0 \leq x \leq 0.5$ in the figure at the bottom right.

(b) The graph of f appears to have a vertical asymptote at $x = 1$ and a horizontal asymptote at $y = 0$.

(c) The function appears to be

decreasing on the intervals $(-\infty, -2)$, $(0, 1)$, and $(1, \infty)$

and increasing on the interval $(-2, 0)$. Additionally, the function appears to be

concave down, approximately, on the intervals $(-\infty, -4)$ and $(0.1, 1)$

and

concave up, approximately, on the intervals $(-4, 0)$, $(0, 0.1)$, and $(1, \infty)$.

(d) The function appears to have a local minimum value at -2 and a local maximum value at 0 .

(e) Note that

$$f'(x) = \frac{(x-1) \cdot \frac{2}{3}x^{-1/3} - x^{2/3}}{(x-1)^2} = \frac{2x-2-3x}{3x^{1/3}(x-1)^2} = -\frac{x+2}{3x^{1/3}(x-1)^2}.$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x) = 0$ when $x = -2$ and does not exist when $x = 0$ and when $x = 1$; however, 1 is not in the domain of f , so 1 is not a critical number. To apply the Increasing/Decreasing Function Test, use the numbers -2 , 0 , and 1 to divide the number line into four intervals.

Interval	Sign of f'	Conclusion
$(-\infty, -2)$	$-$	f is decreasing on $(-\infty, -2)$
$(-2, 0)$	$+$	f is increasing on $(-2, 0)$
$(0, 1)$	$-$	f is decreasing on $(0, 1)$
$(1, \infty)$	$-$	f is decreasing on $(1, \infty)$

By the First Derivative Test and the information in the table above, f has a local minimum value at -2 and a local maximum value at 0 , in agreement with the approximations given in part (d).

- (f) Concavity appears to change at approximately $x = -4$ and $x = 0.1$; therefore,

$$(-4, f(-4)) = \left(-4, -\frac{2\sqrt[3]{2}}{5}\right) \quad \text{and} \quad (0.1, f(0.1)) \approx (0.1, -0.239)$$

are approximate points of inflection of f .

44. Let $f(x) = \frac{5-x}{x^2+3x+4}$.

- (a) The figures below display the graph of f : on the left over the interval $(-20, 20)$, and on the right over the interval $(5, 40)$.

- (b) The graph appears to have a horizontal asymptote at $y = 0$, but no vertical asymptotes.
- (c) The function appears to be increasing, approximately, on the intervals $(-\infty, -2)$ and $(12, \infty)$ and decreasing, approximately, on the interval $(-2, 12)$. Additionally, f appears to be

concave up, approximately, on the intervals $(-\infty, -3)$ and $(-1, 20)$

and

concave down, approximately, on the intervals $(-3, -1)$ and $(20, \infty)$.

- (d) The function appears to have a local maximum value at approximately -2 and a local minimum value at approximately 12 .
- (e) Note that

$$f'(x) = \frac{(x^2 + 3x + 4) \cdot (-1) - (5 - x) \cdot (2x + 3)}{(x^2 + 3x + 4)^2} = \frac{x^2 - 10x - 19}{(x^2 + 3x + 4)^2}.$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ exists everywhere but is equal to zero when

$$x = \frac{10 \pm \sqrt{10^2 - 4(1)(-19)}}{2} = \frac{10 \pm 4\sqrt{11}}{2} \approx -1.633, 11.633.$$

To apply the Increasing/Decreasing Function Test, use the numbers -1.633 and 11.633 to divide the number line into three intervals.

Interval	Sign of f'	Conclusion
$(-\infty, -1.633)$	+	f is increasing on $(-\infty, -1.633)$
$(-1.633, 11.633)$	-	f is decreasing on $(-1.633, 11.633)$
$(11.633, \infty)$	+	f is increasing on $(11.633, \infty)$

By the First Derivative Test and the information in the table above, f has a

local maximum value at approximately -1.633

and a

local minimum value at approximately 11.633 .

The approximations given in part (d) are within 0.4 of the exact values.

- (f) The concavity of f appears to change at -3 , -1 and 20 ; therefore, the points

$$(-3, f(-3)) = (-3, 2), \quad (-1, f(-1)) = (-1, 2), \quad \text{and} \quad (20, f(20)) = \left(20, -\frac{15}{464}\right)$$

are approximate points of inflection of f .

45. Let $f(x) = x + \sin(2x)$.

- (a) The figure below displays the graph of f . Though the function f is not periodic, observe that the graph consists of one basic shape that is repeated every π units along the x -axis.

- (b) The graph of f does not appear to have any asymptotes.
- (c) The function appears to be increasing on the interval $(-1, 1) \approx \left(-\frac{\pi}{3}, \frac{\pi}{3}\right)$ and decreasing on the interval $(1, 2) \approx \left(\frac{\pi}{3}, \frac{2\pi}{3}\right)$. Given the repetitive structure of the graph, it follows that f is

increasing on intervals of the form $\left(-\frac{\pi}{3} + k\pi, \frac{\pi}{3} + k\pi\right)$

and

decreasing on intervals of the form $\left(\frac{\pi}{3} + k\pi, \frac{2\pi}{3} + k\pi\right)$

for each integer k . Additionally, f appears to be concave up on the interval $(-1.5, 0) \approx \left(-\frac{\pi}{2}, 0\right)$ and concave down on the interval $(0, 1.5) \approx \left(0, \frac{\pi}{2}\right)$. Again taking into account the repetitive

structure of the graph, it follows that f is concave up on intervals of the form $\left(-\frac{\pi}{2} + k\pi, k\pi\right)$

and concave down on intervals of the form $\left(k\pi, \frac{\pi}{2} + k\pi\right)$ for each integer k .

- (d) The graph appears to have a local maximum value at approximately $\frac{\pi}{3} + k\pi$ and a local minimum value at approximately $\frac{2\pi}{3} + k\pi$ for each integer k .

- (e) Note

$$f'(x) = 1 + 2\cos(2x).$$

The function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$, which is when $x = \frac{\pi}{3} + k\pi$ and when $x = \frac{2\pi}{3} + k\pi$ for each integer k . To apply the Increasing/Decreasing Function Test, use the numbers $\frac{\pi}{3}$ and $\frac{2\pi}{3}$ to divide $(0, \pi)$ into three intervals.

Interval	Sign of f'	Conclusion
$(0, \frac{\pi}{3})$	+	f is increasing on $(0, \frac{\pi}{3})$
$(\frac{\pi}{3}, \frac{2\pi}{3})$	−	f is decreasing on $(\frac{\pi}{3}, \frac{2\pi}{3})$
$(\frac{2\pi}{3}, \pi)$	+	f is increasing on $(\frac{2\pi}{3}, \pi)$

By the First Derivative Test, the information in the table above and the repetitive structure of the graph, f has a local maximum value at $\frac{\pi}{3} + k\pi$ and a local minimum value at $\frac{2\pi}{3} + k\pi$ for each integer k , in agreement with the approximations given in part (d).

- (f) The concavity of f appears to change at multiples of $\frac{\pi}{2}$; that is, there appear to be points of inflection at

$$\left(\frac{k\pi}{2}, f\left(\frac{k\pi}{2}\right)\right) = \left(\frac{k\pi}{2}, \frac{k\pi}{2}\right)$$

for each integer k .

46. Let $f(x) = x - \cos x$.

- (a) The figure below displays the graph of f . Though the function f is not periodic, observe that the graph consists of one basic shape that is repeated every 2π units along the x -axis.

- (b) The graph of f does not appear to have any asymptotes.

- (c) The function appears to be increasing for all real x . Additionally, f appears to be concave up on the interval $(-1.5, 1.5) \approx \left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$ and concave down on the interval $(1.5, 4.5) \approx \left(\frac{\pi}{2}, \frac{3\pi}{2}\right)$. Given the repetitive structure of the graph, it follows that f is

$$\text{concave up on intervals of the form } \left(-\frac{\pi}{2} + 2k\pi, \frac{\pi}{2} + 2k\pi\right)$$

and

$$\text{concave down on intervals of the form } \left(\frac{\pi}{2} + 2k\pi, \frac{3\pi}{2} + 2k\pi\right)$$

for each integer k .

- (d) The function f does not appear to have any local extreme values.
 (e) Note

$$f'(x) = 1 + \sin x.$$

The function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$, which is when $x = -\frac{\pi}{2} + 2k\pi$ for each integer k . To apply the Increasing/Decreasing Function Test, use the number $\frac{3\pi}{2}$ to divide $(0, 2\pi)$ into two intervals.

Interval	Sign of f'	Conclusion
$(0, \frac{3\pi}{2})$	+	f is increasing on $(0, \frac{3\pi}{2})$
$(\frac{3\pi}{2}, 2\pi)$	+	f is increasing on $(\frac{3\pi}{2}, 2\pi)$

By the First Derivative Test, the information in the table above and the periodic nature of the derivative, f has neither a local maximum value nor a local minimum value at $\frac{3\pi}{2} + 2k\pi$. Therefore, f has no local extreme values, in agreement with the approximations given in part (d).

- (f) The concavity of f appears to change at odd multiples of $\frac{\pi}{2}$; that is, there appear to be points of inflection at

$$\left(\frac{(2k+1)\pi}{2}, f\left(\frac{(2k+1)\pi}{2}\right)\right) = \left(\frac{(2k+1)\pi}{2}, \frac{(2k+1)\pi}{2}\right)$$

for each integer k .

47. Let $f(x) = \ln(x\sqrt{x-1})$.

- (a) The figure below displays the graph of f .

- (b) The graph of f has no horizontal asymptote, but has a vertical asymptote at $x = 1$.
- (c) The function appears to be increasing and concave down on the interval $(1, \infty)$.
- (d) The function f does not appear to have any local extreme values.
- (e) Note that

$$f(x) = \ln(x\sqrt{x-1}) = \ln x + \ln \sqrt{x-1} = \ln x + \frac{1}{2} \ln(x-1),$$

so

$$f'(x) = \frac{1}{x} + \frac{1}{2(x-1)} = \frac{3x-2}{2x(x-1)}.$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x) = 0$ when $x = \frac{2}{3}$ and does not exist when $x = 0$ and when $x = 1$; however, none of these numbers is in the domain of f , so none are critical numbers. Because the function has no critical numbers, there are no local extreme values, in agreement with the result of part (d).

- (f) Because the concavity of f never changes, there are no points of inflection.

48. Let $f(x) = \ln(\tan^2 x)$.

- (a) The figure below displays the graph of f . Note that the graph is periodic with period π .

- (b) The graph of f has no horizontal asymptote, but appears to have a vertical asymptote at $x = \frac{k\pi}{2}$ for each integer k .
- (c) Taking into account the period of the function, f appears to be

increasing on intervals of the form $\left(k\pi, k\pi + \frac{\pi}{2}\right)$

and

decreasing on intervals of the form $\left(k\pi - \frac{\pi}{2}, k\pi\right)$

for each integer k . Additionally, f appears to be

concave up on intervals of the form $\left(-\frac{\pi}{2} + k\pi, -\frac{\pi}{4} + k\pi\right)$ and $\left(\frac{\pi}{4} + k\pi, \frac{\pi}{2} + k\pi\right)$

and

concave down on intervals of the form $\left(-\frac{\pi}{4} + k\pi, k\pi\right)$ and $\left(k\pi, \frac{\pi}{4} + k\pi\right)$,

again for each integer k .

(d) The function f does not appear to have any local extreme values.

(e) Note that

$$f(x) = \ln(\tan^2 x) = 2 \ln \tan x,$$

so

$$f'(x) = \frac{2 \sec^2 x}{\tan x}.$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is never equal to zero and does not exist when $x = \pm \frac{\pi}{2} + k\pi$ for each integer k ; however, none of these numbers is in the domain of f , so none are critical numbers. Because the function has no critical numbers, there are no local extreme values, in agreement with the result of part (d).

(f) The concavity of f appears to change at odd multiples of $\frac{\pi}{4}$; that is, there appear to be points of inflection at

$$\left(\frac{(2k+1)\pi}{4}, f\left(\frac{(2k+1)\pi}{4}\right) \right) = \left(\frac{(2k+1)\pi}{4}, 0 \right)$$

for each integer k .

49. Let $f(x) = \sqrt[3]{\sin x}$.

(a) The figure below displays the graph of f . Note that the graph is periodic with period 2π .

(b) The graph of f does not appear to have any asymptotes.

(c) Taking into account the period of the function, f appears to be

$$\text{increasing on intervals of the form } \left(-\frac{\pi}{2} + 2k\pi, \frac{\pi}{2} + 2k\pi \right)$$

and

$$\text{decreasing on intervals of the form } \left(\frac{\pi}{2} + 2k\pi, \frac{3\pi}{2} + 2k\pi \right)$$

for each integer k . Additionally, f appears to be

$$\text{concave up on intervals of the form } (-\pi + 2k\pi, 2k\pi)$$

and

$$\text{concave down on intervals of the form } (2k\pi, \pi + 2k\pi),$$

again for each integer k .

- (d) The graph appears to have a local maximum value at $x = \frac{\pi}{2} + 2k\pi$ and a local minimum value at $x = \frac{3\pi}{2} + 2k\pi$ for each integer k .

(e) Note

$$f'(x) = \frac{1}{3}(\sin x)^{-2/3} \cos x.$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is equal to zero when $x = \frac{\pi}{2} + k\pi$ for each integer k and does not exist when $x = k\pi$ for each integer k . To apply the Increasing/Decreasing Function Test, use the numbers $\frac{\pi}{2}$, π , and $\frac{3\pi}{2}$ to divide $(0, 2\pi)$ into four intervals.

Interval	Sign of f'	Conclusion
$(0, \frac{\pi}{2})$	+	f is increasing on $(0, \frac{\pi}{2})$
$(\frac{\pi}{2}, \pi)$	−	f is decreasing on $(\frac{\pi}{2}, \pi)$
$(\pi, \frac{3\pi}{2})$	−	f is decreasing on $(\pi, \frac{3\pi}{2})$
$(\frac{3\pi}{2}, 2\pi)$	+	f is increasing on $(\frac{3\pi}{2}, 2\pi)$

By the First Derivative Test, the information in the table above and the periodic nature of the function, f has a local maximum value at $\frac{\pi}{2} + 2k\pi$ and a local minimum value at $\frac{3\pi}{2} + 2k\pi$ for each integer k , in agreement with the approximations given in part (d).

- (f) The concavity of f appears to change at integer multiples of π ; that is, there appear to be points of inflection at $(k\pi, f(k\pi)) = (k\pi, 0)$ for each integer k .

50. Let $f(x) = e^{-x} \cos x$.

- (a) The figures below display the graph of f . In the top figure, the graph is shown for $-2\pi \leq x \leq 2\pi$. In the figure at the bottom left, attention is focused on $-\frac{\pi}{2} \leq x \leq \frac{3\pi}{2}$. Attention is focused on $\frac{3\pi}{2} \leq x \leq \frac{7\pi}{2}$ in the figure at the bottom right. Though the function f is not periodic, observe that the increasing/decreasing and concave up/concave down nature of the function is repeated every 2π units along the x -axis.

(b) The graph appears to have a horizontal asymptote at $y = 0$ for x growing without bound in the positive direction. The graph has no vertical asymptotes.

(c) The function appears to be decreasing on the interval $(-0.8, 2.4) \approx \left(-\frac{\pi}{4}, \frac{3\pi}{4}\right)$ and increasing on the interval $(2.4, 5.6) \approx \left(\frac{3\pi}{4}, \frac{7\pi}{4}\right)$. Given the repetitive structure of the graph, it follows that f is

decreasing on intervals of the form $\left(-\frac{\pi}{4} + 2n\pi, \frac{3\pi}{4} + 2n\pi\right)$

and

increasing on intervals of the form $\left(\frac{3\pi}{4} + 2n\pi, \frac{7\pi}{4} + 2n\pi\right)$

for each integer n . Additionally, f appears to be concave up on the interval $(0, 3.2) \approx (0, \pi)$ and concave down on the interval $(3.2, 6.4) \approx (\pi, 2\pi)$. Again taking into account the repetitive structure of the graph, it follows that f is concave up on intervals of the form $(2n\pi, (2n+1)\pi)$ and concave down on intervals of the form $((2n+1)\pi, (2n+2)\pi)$ for each integer n .

(d) The graph appears to have a local maximum value at $x = -\frac{\pi}{4} + 2n\pi$ and a local minimum value at $x = \frac{3\pi}{4} + 2n\pi$ for each integer n .

(e) Note that

$$f'(x) = -e^{-x} \sin x - e^{-x} \cos x = -e^{-x}(\sin x + \cos x).$$

The function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$, which is when $x = \frac{3\pi}{4} + n\pi$ for each integer n . To apply the Increasing/Decreasing Function Test, use the numbers $\frac{3\pi}{4}$ and $\frac{7\pi}{4}$ to divide $(0, 2\pi)$ into three intervals.

Interval	Sign of f'	Conclusion
$(0, \frac{3\pi}{4})$	−	f is decreasing on $(0, \frac{3\pi}{4})$
$(\frac{3\pi}{4}, \frac{7\pi}{4})$	+	f is increasing on $(\frac{3\pi}{4}, \frac{7\pi}{4})$
$(\frac{7\pi}{4}, 2\pi)$	−	f is decreasing on $(\frac{7\pi}{4}, 2\pi)$

By the First Derivative Test, the information in the table above and the repetitive structure of the graph, f has a local minimum value at $\frac{3\pi}{4} + 2n\pi$ and a local maximum value at $\frac{7\pi}{4} + 2n\pi$ for each integer n , in agreement with the approximations given in part (d).

- (f) The concavity of f appears to change at multiples of π ; that is, there appear to be points of inflection at $\boxed{(n\pi, f(n\pi)) = (n\pi, (-1)^n e^{-n\pi})}$ for each integer n .

51. Let $y^2 = x^2(6 - x)$, and consider $y \geq 0$. Therefore, $y = |x|\sqrt{6 - x}$.

- (a) The figure below displays the graph of $y^2 = x^2(6 - x)$ for $y \geq 0$.

- (b) The graph does not appear to have any asymptotes.

- (c) The function appears to be

decreasing on the intervals $(-\infty, 0)$ and $(4, 6)$

and increasing on the interval $(0, 4)$. Additionally, the function appears to be concave down on the interval $(0, 6)$ and concave up on the interval $(-\infty, 0)$.

- (d) The function appears to have a local minimum value at 0 and a local maximum value at 4.

- (e) Differentiating $y^2 = x^2(6 - x)$ implicitly with respect to x yields

$$2y \frac{dy}{dx} = x^2(-1) + (6 - x)(2x) = -x^2 + 12x - 2x^2 = -3x(x - 4),$$

so that

$$\frac{dy}{dx} = -\frac{3x(x - 4)}{y} = -\frac{3x(x - 4)}{|x|\sqrt{6 - x}}.$$

The critical numbers of y occur where $y'(x) = 0$ and where $y'(x)$ does not exist. $y'(x) = 0$ when $x = 4$ and does not exist when $x = 0$ and when $x = 6$. To apply the Increasing/Decreasing Function Test, use the numbers 0 and 4 to divide the domain of y , the set $\{x | x \leq 6\}$, into three intervals.

Interval	Sign of y'	Conclusion
$(-\infty, 0)$	−	y is decreasing on $(-\infty, 0)$
$(0, 4)$	+	y is increasing on $(0, 4)$
$(4, 6)$	−	y is decreasing on $(4, 6)$

By the First Derivative Test and the information in the table above, y has a local minimum value at 0 and a local maximum value at 4, in agreement with the approximations given in part (d).

- (f) The concavity of the graph appears to change at 0; that is, there appears to be a point of inflection at $(0, 0)$.

52. Let $y^2 = x^2(4 - x^2)$, and consider $y \geq 0$. Therefore, $y = |x|\sqrt{4 - x^2}$.

(a) The figure below displays the graph of $y^2 = x^2(4 - x^2)$ for $y \geq 0$.

(b) The graph does not appear to have any asymptotes.

(c) The function appears to be

increasing on the intervals $(-2, -1.4)$ and $(0, 1.4)$

and decreasing on the interval $(-1.4, 0)$ and $(1.4, 2)$. Additionally, the function appears to be concave down on the intervals $(-2, 0)$ and $0, 2$.

(d) The function appears to have a local minimum value at 0 and local maximum values at ± 1.4 .

(e) Differentiating $y^2 = x^2(4 - x^2)$ implicitly with respect to x yields

$$2y \frac{dy}{dx} = x^2(-2x) + (4 - x^2)(2x) = 2x(-x^2 + 4 - x^2) = 4x(2 - x^2),$$

so that

$$\frac{dy}{dx} = \frac{4x(2 - x^2)}{y} = \frac{4x(2 - x^2)}{|x|\sqrt{4 - x^2}}.$$

The critical numbers of y occur where $y'(x) = 0$ and where $y'(x)$ does not exist. $y'(x) = 0$ when $x = \pm\sqrt{2}$ and does not exist when $x = 0$ and when $x = \pm 2$. To apply the Increasing/Decreasing Function Test, use the numbers 0 and $\pm\sqrt{2}$ to divide the domain of y , the set $\{x \mid -2 \leq x \leq 2\}$, into four intervals.

Interval	Sign of y'	Conclusion
$(-2, -\sqrt{2})$	+	y is increasing on $(-2, -\sqrt{2})$
$(-\sqrt{2}, 0)$	−	y is decreasing on $(-\sqrt{2}, 0)$
$(0, \sqrt{2})$	+	y is increasing on $(0, \sqrt{2})$
$(\sqrt{2}, 2)$	−	y is decreasing on $(\sqrt{2}, 2)$

By the First Derivative Test and the information in the table above, y has a local minimum value at 0 and local maximum values at $\pm\sqrt{2}$, in excellent agreement with the approximations given in part (d).

(f) The concavity of the graph does not appear to change, so there appear to be no points of inflection.

53. Answers will vary. The figure below displays the graph of a function f that is continuous on the interval $[2, 5]$ and satisfies the following conditions: $f'(2)$ does not exist, $f'(3) = -1$, $f''(3) = 0$, $f'(5) = 0$, $f''(x) < 0$ for $2 < x < 3$, and $f''(x) > 0$ for $x > 3$.

54. Answers will vary. The figure below displays the graph of a function f that is continuous on the interval $[2, 5]$ and satisfies the following conditions: $f'(2) = 0$, $f''(2) = 0$, $f'(3)$ does not exist, $f'(5) = 0$, $f''(x) > 0$ for $2 < x < 3$, and $f''(x) < 0$ for $x > 3$.

55. Answers will vary. The figure below displays the graph of a function f that is continuous on the interval $[2, 5]$ and satisfies the following conditions: $f'(2) = 0$, $\lim_{x \rightarrow 3^-} f'(x) = \infty$, $\lim_{x \rightarrow 3^+} f'(x) = \infty$, $f'(5) = 0$, $f''(x) > 0$ for $x < 3$, and $f''(x) < 0$ for $x > 3$.

56. Answers will vary. The figure below displays the graph of a function f that is continuous on the interval $[2, 5]$ and satisfies the following conditions: $f'(2) = 0$, $\lim_{x \rightarrow 3^-} f'(x) = -\infty$, $\lim_{x \rightarrow 3^+} f'(x) = -\infty$, $f'(5) = 0$, $f''(x) < 0$ for $x < 3$, and $f''(x) > 0$ for $x > 3$.

57. Answers will vary. The figure below displays the graph of a function f that is continuous on the interval $[-1, 2]$ and satisfies the following conditions: $f(-1) = 1$, $f(1) = 2$, $f(2) = 3$, $f(0) = 0$, $f\left(\frac{1}{2}\right) = 3$, $\lim_{x \rightarrow -1^+} f'(x) = -\infty$, $\lim_{x \rightarrow 1^-} f'(x) = -1$, $\lim_{x \rightarrow 1^+} f'(x) = \infty$, f has a local minimum at 0, and f has a local maximum at $\frac{1}{2}$.

58. Let $y = f(x) = \ln|x^2 - 1|$, and consider the interval $(-1, 1)$. On the interval $(-1, 1)$, $x^2 - 1 < 0$, so $|x^2 - 1| = -(x^2 - 1) = 1 - x^2$ and $f(x) = \ln(1 - x^2)$. Now,

$$\begin{aligned} f'(x) &= -\frac{2x}{1 - x^2}; \text{ and} \\ f''(x) &= \frac{(1 - x^2) \cdot (-2) - (-2x) \cdot (-2x)}{(1 - x^2)^2} = -\frac{2(x^2 + 1)}{(1 - x^2)^2}. \end{aligned}$$

- (a) False. Because $f'(x) > 0$ for $-1 < x < 0$ and $f'(x) < 0$ for $0 < x < 1$, it follows that f is increasing on the interval $(-1, 0)$ and decreasing on the interval $(0, 1)$.
- (b) False. By the First Derivative Test, f has a local maximum at $(0, 0)$.
- (c) False. The range of f is the set $\{y | y \leq 0\}$.
- (d) True. Because $f''(x) < 0$ for $-1 < x < 1$, f is concave down on the interval $(-1, 1)$.
- (e) False. $\lim_{x \rightarrow 0} \ln(1 - x^2) = \ln 1 = 0$, so there is no vertical asymptote at $x = 0$. The vertical asymptotes are at $x = \pm 1$.
59. Let $f(x) = \frac{1}{x} + \ln x$, and suppose the function is defined only on the closed interval $\left[\frac{1}{e}, e\right]$.

- (a) Absolute extreme values can only occur at endpoints and critical numbers. The function f is differentiable on the domain $\left[\frac{1}{e}, e\right]$, so critical numbers occur where $f'(x) = 0$. Now,

$$f'(x) = -\frac{1}{x^2} + \frac{1}{x} = \frac{x - 1}{x^2},$$

so $f'(x) = 0$ when $x = 1$. Evaluating f at the endpoints of the interval $\left[\frac{1}{e}, e\right]$ and the critical number 1 yields

$$\begin{aligned} f\left(\frac{1}{e}\right) &= e + \ln\left(\frac{1}{e}\right) = e - 1 \approx 1.718 \\ f(1) &= 1 + \ln 1 = 1 \\ f(e) &= \frac{1}{e} + \ln e = \frac{1}{e} + 1 \approx 1.368 \end{aligned}$$

The absolute maximum value of f is $e - 1$, which occurs at $x = \frac{1}{e}$, and the absolute minimum value of f is 1, which occurs at $x = 1$.

(b) With

$$f''(x) = \frac{2}{x^3} - \frac{1}{x^2} = \frac{2-x}{x^3},$$

it follows that $f''(x) > 0$ for $\frac{1}{e} < x < 2$ and $f''(x) < 0$ for $2 < x < e$. Therefore, f is

concave up on the interval $\left(\frac{1}{e}, 2\right)$ and concave down on the interval $(2, e)$.

(c) The figure below displays the graph of f .

60. Let $f(x) = \frac{1}{\sqrt{2\pi}}e^{-x^2/2}$. Then

$$\begin{aligned} f'(x) &= -\frac{1}{\sqrt{2\pi}}xe^{-x^2/2}; \text{ and} \\ f''(x) &= \frac{1}{\sqrt{2\pi}}(x^2e^{-x^2/2} - e^{-x^2/2}) = \frac{1}{\sqrt{2\pi}}(x^2 - 1)e^{-x^2/2}. \end{aligned}$$

The function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$, which is when $x = 0$. To apply the Increasing/Decreasing Function Test, use the number 0 to divide the number line into two intervals.

Interval	Sign of f'	Conclusion
$(-\infty, 0)$	+	f is increasing on $(-\infty, 0)$
$(0, \infty)$	-	f is decreasing on $(0, \infty)$

By the First Derivative Test and the information in the table above, f has a local maximum value at 0. The local maximum value is $f(0) = \frac{1}{\sqrt{2\pi}}$. The second derivative exists everywhere but is equal to zero when $x = \pm 1$. Use these numbers to divide the number line into three intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, -1)$	+	f is concave up on $(-\infty, -1)$
$(-1, 1)$	-	f is concave down on $(-1, 1)$
$(1, \infty)$	+	f is concave up on $(1, \infty)$

The concavity of f changes at ± 1 , so the points $\left(-1, \frac{1}{\sqrt{2\pi}}e^{-1/2}\right)$ and $\left(1, \frac{1}{\sqrt{2\pi}}e^{-1/2}\right)$ are points of inflection. The figure below displays the graph of f . The local extreme value is highlighted by a closed circle, and the points of inflection are highlighted by closed squares.

61. Let $f(x) = \frac{\sin(3x)}{x\sqrt{4-x^2}}$.

Step 1 The domain of f is the set $\{x | -2 < x < 0\} \cup \{x | 0 < x < 2\}$. The x -intercepts are $\pm \frac{\pi}{3}$, and there is no y -intercept because $x = 0$ is not in the domain of f .

Step 2 Because

$$\lim_{x \rightarrow -2^+} \frac{\sin(3x)}{x\sqrt{4-x^2}} = -\infty \quad \text{and} \quad \lim_{x \rightarrow 2^-} \frac{\sin(3x)}{x\sqrt{4-x^2}} = -\infty,$$

the lines $x = \pm 2$ are vertical asymptotes. On the other hand, by L'Hôpital's Rule,

$$\lim_{x \rightarrow 0} \frac{\sin(3x)}{x\sqrt{4-x^2}} = \lim_{x \rightarrow 0} \frac{3 \cos(3x)}{x \cdot \left(-\frac{x}{\sqrt{4-x^2}}\right) + \sqrt{4-x^2}} = \lim_{x \rightarrow 0} \frac{3\sqrt{4-x^2} \cos(3x)}{4-2x^2} = \frac{3}{2},$$

so $x = 0$ is not a vertical asymptote; rather, the graph of f has a missing point at $\left(0, \frac{3}{2}\right)$. The graph has no horizontal asymptotes because f is not defined for $|x| \geq 2$.

Step 3 Now,

$$\begin{aligned} f'(x) &= \frac{x\sqrt{4-x^2} \cdot 3 \cos(3x) - \sin(3x) \left(x \cdot \frac{1}{2}(x^2-4)^{-1/2}(-2x) + \sqrt{4-x^2}\right)}{x^2(4-x^2)} \\ &= \frac{3x(4-x^2) \cos(3x) - (4-2x^2) \sin(3x)}{x^2(4-x^2)^{3/2}}; \text{ and} \\ f''(x) &= \frac{(-9x^6 + 78x^4 - 164x^2 + 32) \sin(3x) - 12x(x^4 - 6x^2 + 8) \cos(3x)}{x^3(4-x^2)^{5/2}}, \end{aligned}$$

where the second derivative was obtained using *Mathematica*. The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. Using the command

`Solve [ D [ Sin[3x]/(x Sqrt[4-x^2]), x ] == 0, x ]`

in *Wolfram Alpha*, we find that $f'(x) = 0$ when $x \approx \pm 1.642$ and $x \approx \pm 1.908$. Now, $f'(x)$ does not exist when $x = 0$ and when $x = \pm 2$; however, because none of these values are in the domain of f , none are critical numbers. Therefore, ± 1.642 and ± 1.908 are the critical numbers of f . At the points $(\pm 1.642, -0.521)$ and $(\pm 1.908, -0.464)$, the tangent lines are horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the numbers 0, ± 1.642 and ± 1.908 to divide the interval $(-2, 2)$ into six subintervals.

Interval	Sign of f'	Conclusion
$(-2, -1.908)$	+	f is increasing on $(-2, -1.908)$
$(-1.908, -1.642)$	-	f is decreasing on $(-1.908, -1.642)$
$(-1.642, 0)$	+	f is increasing on $(-1.642, 0)$
$(0, 1.642)$	-	f is decreasing on $(0, 1.642)$
$(1.642, 1.908)$	+	f is increasing on $(1.642, 1.908)$
$(1.908, 2)$	-	f is decreasing on $(1.908, 2)$

Step 5 By the First Derivative Test and the information in the table above, f has a local maximum value at ± 1.908 and a local minimum value at ± 1.642 . The

$$\text{local maximum values are } f(\pm 1.908) \approx -0.461,$$

and the

$$\text{local minimum values are } f(\pm 1.642) \approx -0.521.$$

Step 6 The second derivative does not exist when $x = 0$ and when $x = \pm 2$ and is equal to zero when $x \approx \pm 0.763$ and when $x \approx \pm 1.826$. These latter values were obtained using the command

$$\text{Solve [D [Sin[3x]/(x Sqrt[4-x^2]) , \{x, 2\}] == 0 , x]}$$

in *Wolfram Alpha*. Use the numbers 0, ± 0.763 and ± 1.826 to divide the interval $(-2, 2)$ into six subintervals, and determine the sign of f'' on each subinterval.

Interval	Sign of f''	Conclusion
$(-2, -1.826)$	-	f is concave down on $(-2, -1.826)$
$(-1.826, -0.763)$	+	f is concave up on $(-1.826, -0.763)$
$(-0.763, 0)$	-	f is concave down on $(-0.763, 0)$
$(0, 0.763)$	-	f is concave down on $(0, 0.763)$
$(0.763, 1.826)$	+	f is concave up on $(0.763, 1.826)$
$(1.826, 2)$	-	f is concave down on $(1.826, 2)$

The concavity of f changes at approximately ± 0.763 and ± 1.826 , so the points

$$(\pm 0.763, 0.534) \quad \text{and} \quad (\pm 1.826, -0.484)$$

are approximate points of inflection of f .

Step 7 The figure below displays the graph of f . The local extreme values are highlighted by closed circles, and the points of inflection are highlighted by closed squares.

62. Let $f(x) = x^{\sqrt{x}}$.

Step 1 The domain of f is the set $\{x|x > 0\}$. There are no x -intercepts, and there is no y -intercept because $x = 0$ is not in the domain of f .

Step 2 Because

$$\lim_{x \rightarrow \infty} x^{\sqrt{x}} = \infty,$$

the graph of f has no horizontal asymptote. At 0^+ , the expression $x^{\sqrt{x}}$ is an indeterminate form of the type 0^0 . Let $y = x^{\sqrt{x}}$. Then

$$\ln y = \ln x^{\sqrt{x}} = \sqrt{x} \ln x,$$

which is an indeterminate form at 0^+ of the type $0 \cdot \infty$. Rewrite

$$\sqrt{x} \ln x \quad \text{as} \quad \frac{\ln x}{x^{-1/2}},$$

which is now an indeterminate form at 0^+ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 0^+} \ln y = \lim_{x \rightarrow 0^+} [\sqrt{x} \ln x] = \lim_{x \rightarrow 0^+} \frac{\ln x}{x^{-1/2}} = \lim_{x \rightarrow 0^+} \frac{x^{-1}}{-\frac{1}{2}x^{-3/2}} = \lim_{x \rightarrow 0^+} (-2x^{1/2}) = 0.$$

Because $\lim_{x \rightarrow 0^+} \ln y = 0$, it follows that

$$\lim_{x \rightarrow 0^+} y = \lim_{x \rightarrow 0^+} x^{\sqrt{x}} = e^0 = 1,$$

so $x = 0$ is not a vertical asymptote; rather, the graph of f has a missing point at $(0, 1)$.

Step 3 To determine $f'(x)$, first take the natural logarithm of both sides of $f(x) = x^{\sqrt{x}}$ to obtain $\ln f(x) = \ln x^{\sqrt{x}} = \sqrt{x} \ln x$. Now, by implicit differentiation,

$$\frac{1}{f(x)} f'(x) = \sqrt{x} \cdot \frac{1}{x} + \frac{1}{2\sqrt{x}} \ln x = \frac{2 + \ln x}{2\sqrt{x}},$$

so that

$$f'(x) = x^{\sqrt{x}} \frac{2 + \ln x}{2\sqrt{x}}.$$

Next,

$$\begin{aligned}
 f''(x) &= x^{\sqrt{x}} \frac{d}{dx} \left(\frac{2 + \ln x}{2\sqrt{x}} \right) + \frac{2 + \ln x}{2\sqrt{x}} \frac{d}{dx} x^{\sqrt{x}} \\
 &= x^{\sqrt{x}} \frac{2\sqrt{x} \cdot \frac{1}{x} - (2 + \ln x)x^{-1/2}}{4x} + x^{\sqrt{x}} \left(\frac{2 + \ln x}{2\sqrt{x}} \right)^2 \\
 &= x^{\sqrt{x}} \left[-\frac{\ln x}{4x^{3/2}} + \left(\frac{2 + \ln x}{2\sqrt{x}} \right)^2 \right].
 \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. Now, $f'(x) = 0$ when $x = \frac{1}{e^2}$ and does not exist when $x = 0$. However, $x = 0$ is not in the domain of f , so $x = 0$ is not a critical number of f . Therefore, $\boxed{\frac{1}{e^2}}$ is the only critical number of f . At the point $\left(\frac{1}{e^2}, \frac{1}{e^{2/e}}\right) \approx (0.135, 0.479)$, the tangent line is horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the number $\frac{1}{e^2}$ to divide the interval $(0, \infty)$ into two subintervals.

Interval	Sign of f'	Conclusion
$(0, \frac{1}{e^2})$	–	f is decreasing on $(0, \frac{1}{e^2})$
$(\frac{1}{e^2}, \infty)$	+	f is increasing on $(\frac{1}{e^2}, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local minimum value at $\frac{1}{e^2}$. The $\boxed{\text{local minimum value is } f\left(\frac{1}{e^2}\right) = \frac{1}{e^{2/e}} \approx 0.479}$.

Step 6 For $0 < x < 1$,

$$-\frac{\ln x}{4x^{3/2}} > 0, \quad \text{so that} \quad -\frac{\ln x}{4x^{3/2}} + \left(\frac{2 + \ln x}{2\sqrt{x}}\right)^2 > 0 \quad \text{and} \quad f''(x) > 0.$$

For $x > 1$,

$$-\frac{\ln x}{4x^{3/2}} > -\frac{\ln x}{4x} > -\frac{8 \ln x}{4x},$$

so that

$$-\frac{\ln x}{4x^{3/2}} + \left(\frac{2 + \ln x}{2\sqrt{x}}\right)^2 > -\frac{8 \ln x}{4x} + \left(\frac{2 + \ln x}{2\sqrt{x}}\right)^2 = \left(\frac{2 - \ln x}{2\sqrt{x}}\right)^2 \geq 0 \quad \text{and} \quad f''(x) > 0.$$

Finally,

$$f''(1) = 1^{\sqrt{1}} \left[-\frac{\ln 1}{4(1)^{3/2}} + \left(\frac{2 + \ln 1}{2\sqrt{1}}\right)^2 \right] = 1 > 0.$$

Therefore, $f''(x) > 0$ for all $x > 0$, and f is concave up for all $x > 0$. Because the concavity of f never changes, there are $\boxed{\text{no points of inflection}}$.

Step 7 The figure below displays the graph of f . The local extreme value is highlighted by a closed circle.

63. Let $f(x) = x^{1/x}$.

Step 1 The domain of f is the set $\{x|x > 0\}$. There are no x -intercepts, and there is no y -intercept because $x = 0$ is not in the domain of f .

Step 2 At ∞ , the expression $x^{1/x}$ is an indeterminate form of the type ∞^0 . Let $y = x^{1/x}$. Then

$$\ln y = \ln x^{1/x} = \frac{1}{x} \ln x = \frac{\ln x}{x},$$

which is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow \infty} \ln y = \lim_{x \rightarrow \infty} \frac{\ln x}{x} = \lim_{x \rightarrow \infty} \frac{\frac{1}{x}}{1} = 0.$$

Because $\lim_{x \rightarrow \infty} \ln y = 0$, it follows that

$$\lim_{x \rightarrow \infty} y = \lim_{x \rightarrow \infty} x^{1/x} = e^0 = 1,$$

so $y = 1$ is a horizontal asymptote. At 0^+ , the expression $x^{1/x}$ is of the form 0^∞ , which is not an indeterminate form; rather,

$$\lim_{x \rightarrow 0^+} x^{1/x} = 0.$$

The graph of f has a missing point at $(0, 0)$ and not a vertical asymptote at $x = 0$.

Step 3 To determine $f'(x)$, first take the natural logarithm of both sides of $f(x) = x^{1/x}$ to obtain $\ln f(x) = \ln x^{1/x} = \frac{1}{x} \ln x$. Now, by implicit differentiation,

$$\frac{1}{f(x)} f'(x) = \frac{1}{x} \cdot \frac{1}{x} - \frac{1}{x^2} \ln x = \frac{1 - \ln x}{x^2},$$

so that

$$f'(x) = x^{1/x} \frac{1 - \ln x}{x^2}.$$

Next,

$$\begin{aligned} f''(x) &= x^{1/x} \frac{d}{dx} \left(\frac{1 - \ln x}{x^2} \right) + \frac{1 - \ln x}{x^2} \frac{d}{dx} x^{1/x} \\ &= x^{1/x} \frac{x^2 \left(-\frac{1}{x} \right) - (1 - \ln x)(2x)}{x^4} + x^{1/x} \left(\frac{1 - \ln x}{x^2} \right)^2 \\ &= x^{1/x} \left[\frac{2 \ln x - 3}{x^3} + \left(\frac{1 - \ln x}{x^2} \right)^2 \right]. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. Now, $f'(x) = 0$ when $x = e$ and does not exist when $x = 0$. However, $x = 0$ is not in the domain of f , so $x = 0$ is not a critical number of f . Therefore, $[e]$ is the only critical number of f . At the point $(e, e^{1/e}) \approx (2.718, 1.445)$, the tangent line is horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the number e to divide the interval $(0, \infty)$ into two subintervals.

Interval	Sign of f'	Conclusion
$(0, e)$	+	f is increasing on $(0, e)$
(e, ∞)	−	f is decreasing on (e, ∞)

Step 5 By the First Derivative Test and the information in the table above, f has a local maximum value at e . The local maximum value is $f(e) = e^{1/e} \approx 1.445$.

Step 6 The second derivative exists for all $x > 0$ and is equal to zero when $x \approx 0.582$ and when $x \approx 4.368$. These latter values were obtained using the command

Solve [D [$x^{1/x}$, {x, 2}] == 0, x]

in *Wolfram Alpha*. Use the numbers 0.582 and 4.368 to divide the interval $(0, \infty)$ into three subintervals, and determine the sign of f'' on each subinterval.

Interval	Sign of f''	Conclusion
$(0, 0.582)$	+	f is concave up on $(0, 0.582)$
$(0.582, 4.368)$	−	f is concave down on $(0.582, 4.368)$
$(4.368, \infty)$	+	f is concave up on $(4.368, \infty)$

The concavity of f changes at approximately 0.582 and 4.368, so the points

$(0.582, 0.395)$ and $(4.368, 1.401)$

are approximate points of inflection of f .

Step 7 The figure below displays the graph of f . The local extreme value is highlighted by a closed circle, and the points of inflection are highlighted by closed squares.

64. Let $f(x) = \frac{1}{x} \tan x$, and consider the interval $-\frac{\pi}{2} < x < \frac{\pi}{2}$.

Step 1 The domain of f is the set $\left\{x \mid -\frac{\pi}{2} < x < 0\right\} \cup \left\{0 < x < \frac{\pi}{2}\right\}$. There are no x -intercepts, and there is no y -intercept because $x = 0$ is not in the domain of f .

Step 2 Because

$$\lim_{x \rightarrow -\pi/2^+} \frac{\tan x}{x} = \infty \quad \text{and} \quad \lim_{x \rightarrow \pi/2^-} \frac{\tan x}{x} = \infty,$$

the lines $x = \pm\pi/2$ are vertical asymptotes. On the other hand, by L'Hôpital's Rule,

$$\lim_{x \rightarrow 0} \frac{\tan x}{x} = \lim_{x \rightarrow 0} \frac{\sec^2 x}{1} = 1,$$

so the graph of f does not have a vertical asymptote at $x = 0$; rather, the graph has a missing point at $(0, 1)$.

Step 3 Now,

$$\begin{aligned} f'(x) &= \frac{x \sec^2 x - \tan x}{x^2}; \text{ and} \\ f''(x) &= \frac{x^2 (x \cdot 2 \sec x \cdot \sec x \tan x + \sec^2 x - \sec^2 x) - 2x (x \sec^2 x - \tan x)}{x^4} \\ &= \frac{2x^2 \sec^2 x \tan x - 2x \sec^2 x + 2 \tan x}{x^3}. \end{aligned}$$

Note that $x \sec^2 x - \tan x = 0$ when

$$x = \frac{\tan x}{\sec^2 x} = \sin x \cos x = \frac{1}{2} \sin(2x).$$

The only solution of this equation is $x = 0$. However, $x = 0$ is not in the domain of f , so $x = 0$ is not a critical number of f . Therefore, f has no critical numbers.

Step 4 To apply the Increasing/Decreasing Function Test, use the number 0 to divide the interval $(-\frac{\pi}{2}, \frac{\pi}{2})$ into two subintervals.

Interval	Sign of f'	Conclusion
$(-\frac{\pi}{2}, 0)$	–	f is decreasing on $(-\frac{\pi}{2}, 0)$
$(0, \frac{\pi}{2})$	+	f is increasing on $(0, \frac{\pi}{2})$

Step 5 Because f has no critical numbers, f has no local extrema.

Step 6 The second derivative is never equal to 0 on the interval $(-\frac{\pi}{2}, \frac{\pi}{2})$ (use *Mathematica*, for example) and does not exist when $x = 0$. Use the number 0 to divide the interval $(-\frac{\pi}{2}, \frac{\pi}{2})$ into two subintervals, and determine the sign of f'' on each subinterval.

Interval	Sign of f''	Conclusion
$(-\frac{\pi}{2}, 0)$	+	f is concave up on $(-\frac{\pi}{2}, 0)$
$(0, \frac{\pi}{2})$	+	f is concave up on $(0, \frac{\pi}{2})$

Because the concavity of f does not change, f has no points of inflection.

Step 7 The figure below displays the graph of f .

4.7: Optimization

Applications and Extensions

1. Let x denote the length of fencing used to enclose the plot on each side perpendicular to the highway and y the length of fencing used parallel to the highway (see the diagram below). The area A enclosed by the fencing is then $A = xy$. With 3000 m of fencing available, x and y are related by the equation

$$2x + y = 3000 \quad \text{or} \quad y = 3000 - 2x.$$

Substituting for y in the area formula yields

$$A = x(3000 - 2x) = 3000x - 2x^2.$$

The domain of this function is the closed interval $[0, 1500]$. The function A is differentiable on the open interval $(0, 1500)$, so the critical numbers occur where $A'(x) = 0$. Now,

$$A'(x) = 3000 - 4x,$$

so $A'(x) = 0$ when $x = 750$. Evaluating A at the endpoints of the interval $[0, 1500]$ and at the critical number 750 yields

$$A(0) = 0, \quad A(750) = 1,125,000, \quad \text{and} \quad A(1500) = 0.$$

The largest area that can be enclosed is therefore $\boxed{1,125,000 \text{ m}^2}$, achieved by using 1500 m of fencing parallel to the highway and 750 m of fencing on each side perpendicular to the highway.

2. Let x denote the length of fencing used to enclose the plot on each side perpendicular to the highway and y the length of fencing used parallel to the highway (see the diagram below). The area A enclosed by the fencing is then $A = xy$. With 3000 m of fencing available, x and y are related by the equation

$$2x + 2y - 5 = 3000 \quad \text{or} \quad y = \frac{3005}{2} - x.$$

Substituting for y in the area formula yields

$$A = x \left(\frac{3005}{2} - x \right) = \frac{3005}{2}x - x^2.$$

The domain of this function is the closed interval $\left[0, \frac{3005}{2}\right] = [0, 1502.5]$. The function A is differentiable on the open interval $(0, 1502.5)$, so the critical numbers occur where $A'(x) = 0$. Now,

$$A'(x) = \frac{3005}{2} - 2x,$$

so $A'(x) = 0$ when $x = \frac{3005}{4} = 751.25$. Evaluating A at the endpoints of the interval $[0, 1502.5]$ and at the critical number 751.25 yields

$$A(0) = 0, \quad A(751.25) = 564,376.5625, \quad \text{and} \quad A(1502.5) = 0.$$

The largest area that can be enclosed is therefore $\boxed{564,376.5625 \text{ m}^2}$, achieved by using 751.25 m of fencing on each side perpendicular to the highway, 751.25 m of fencing parallel to the highway on the side without the access opening, and 746.25 m of fencing parallel to the highway on the side with the access opening.

3. Let x and y denote the width and length of the rectangular plot enclosed on all sides by fencing (see the diagram below). The area A enclosed by the fencing is then $A = xy$. With L m of fencing available, x and y are related by the equation

$$2x + 2y = L \quad \text{or} \quad y = \frac{L}{2} - x.$$

Substituting for y in the area formula yields

$$A = x \left(\frac{L}{2} - x \right) = \frac{L}{2}x - x^2.$$

The domain of this function is the closed interval $\left[0, \frac{L}{2}\right]$. The function A is differentiable on the open interval $\left(0, \frac{L}{2}\right)$, so the critical numbers occur where $A'(x) = 0$. Now,

$$A'(x) = \frac{L}{2} - 2x,$$

so $A'(x) = 0$ when $x = \frac{L}{4}$. Evaluating A at the endpoints of the interval $\left[0, \frac{L}{2}\right]$ and at the critical number $\frac{L}{4}$ yields

$$A(0) = 0, \quad A\left(\frac{L}{4}\right) = \frac{L^2}{16}, \quad \text{and} \quad A\left(\frac{L}{2}\right) = 0.$$

The largest area that can be enclosed is therefore $\frac{L^2}{16}$ m², achieved by using $L/4$ m of fencing on each side of the rectangle; that is, by making a square plot with dimensions $\boxed{\frac{L}{4} \text{ m} \times \frac{L}{4} \text{ m}}$.

4. Using the diagram in the text, the length of the third side of the triangle is $2x \cos \theta$ and the height of the triangle is $x \sin \theta$. Therefore, the area A of the triangle is $A = x^2 \sin \theta \cos \theta$. Given that the perimeter of the triangle is fixed at L , x and θ are related by the equation

$$2x + 2x \cos \theta = L \quad \text{or} \quad x = \frac{L}{2(1 + \cos \theta)}.$$

Substituting for x in the area formula yields

$$A = \left(\frac{L}{2(1 + \cos \theta)} \right)^2 \sin \theta \cos \theta = \frac{L^2}{4} \frac{\sin \theta \cos \theta}{(1 + \cos \theta)^2}.$$

The domain of this function is the closed interval $\left[0, \frac{\pi}{2}\right]$. Now,

$$\begin{aligned}
 A'(\theta) &= \frac{L^2}{4} \cdot \frac{(1 + \cos \theta)^2 (\cos^2 \theta - \sin^2 \theta) - 2(1 + \cos \theta)(-\sin \theta)(\sin \theta \cos \theta)}{(1 + \cos \theta)^4} \\
 &= \frac{L^2}{4} \cdot \frac{\cos^2 \theta + \cos^3 \theta - \sin^2 \theta - \sin^2 \theta \cos \theta + 2 \sin \theta \cos \theta}{(1 + \cos \theta)^3} \\
 &= \frac{L^2}{4} \cdot \frac{\cos^2 \theta + \cos \theta (\sin^2 \theta + \cos^2 \theta) - 1 + \cos^2 \theta}{(1 + \cos \theta)^3} \\
 &= \frac{L^2}{4} \cdot \frac{2 \cos^2 \theta + \cos \theta - 1}{(1 + \cos \theta)^3} \\
 &= \frac{L^2}{4} \cdot \frac{(2 \cos \theta - 1)(1 + \cos \theta)}{(1 + \cos \theta)^3} = \frac{L^2}{4} \cdot \frac{2 \cos \theta - 1}{(1 + \cos \theta)^2},
 \end{aligned}$$

so the only critical number in the open interval $\left(0, \frac{\pi}{2}\right)$ is $\frac{\pi}{3}$, where $A'\left(\frac{\pi}{3}\right) = 0$. Evaluating A at the endpoints of the domain and at the critical number $\frac{\pi}{3}$ yields

$$A(0) = 0, \quad A\left(\frac{\pi}{3}\right) = \frac{L^2 \sqrt{3}}{36}, \quad \text{and} \quad A\left(\frac{\pi}{2}\right) = 0.$$

The maximum area is therefore enclosed by the triangle with $\theta = \frac{\pi}{3}$. Then

$$x = \frac{L}{2(1 + \cos \theta)} = \frac{L}{2(1 + \frac{1}{2})} = \frac{L}{3},$$

so the resulting triangle has all sides with length equal to $L/3$; that is, the triangle with maximum area is an equilateral triangle with side length $L/3$.

5. Using the diagram in the text, let x denote the length of each of the three vertical sides and y denote the length of each of the two horizontal sides. The area A enclosed by the fencing is then $A = xy$. With 200 m of fencing available, x and y are related by the equation

$$2y + 3x = 200 \quad \text{or} \quad y = 100 - \frac{3}{2}x.$$

Substituting for y in the area formula yields

$$A = x \left(100 - \frac{3}{2}x\right) = 100x - \frac{3}{2}x^2.$$

The domain of this function is the closed interval $\left[0, \frac{200}{3}\right]$. The function A is differentiable on the open interval $\left(0, \frac{200}{3}\right)$, so the critical numbers occur where $A'(x) = 0$. Now,

$$A'(x) = 100 - 3x,$$

so $A'(x) = 0$ when $x = \frac{100}{3}$. Evaluating A at the endpoints of the interval $\left[0, \frac{200}{3}\right]$ and at the critical number $\frac{100}{3}$ yields

$$A(0) = 0, \quad A\left(\frac{100}{3}\right) = \frac{5000}{3}, \quad \text{and} \quad A\left(\frac{200}{3}\right) = 0.$$

The largest area that can be enclosed is therefore $\frac{5000}{3} \text{ m}^2$.

6. Let x and y denote the length and width of the rectangular plot of land, and suppose that the extra fencing used to divide the large plot into two pieces has length y (see the diagram below). The amount of fencing F used to enclose the plots is then $F = 2x + 3y$. Given that the area enclosed has to be equal to 600 m^2 , x and y are related by the equation

$$xy = 600 \quad \text{or} \quad y = \frac{600}{x}.$$

Substituting for y in the fencing formula yields

$$F = 2x + 3\left(\frac{600}{x}\right) = 2x + \frac{1800}{x}.$$

The domain for this function is the open interval $(0, \infty)$. Now,

$$F'(x) = 2 - \frac{1800}{x^2},$$

so the only critical number in the open interval $(0, \infty)$ is 30, where $F'(30) = 0$. Note that $x = -30$ and $x = 0$ are not in the domain of F . Using the Second Derivative Test,

$$F''(x) = \frac{3600}{x^3}, \quad \text{so} \quad F''(30) = \frac{3600}{30^3} > 0$$

and F has a local minimum value at 30. Because $F''(x) > 0$ for all $x > 0$, the local minimum is also an absolute minimum. Therefore, the minimum amount of fencing is used to enclose the plot when $x = 30$ and $y = \frac{600}{30} = 20$. A 30 m $\times$ 20 m enclosure uses the least amount of fencing.

7. Let x denote the side length of the square cut from each corner of the base (see the diagram below). When the sides are turned up, the resulting box will have a square base $12 - 2x$ cm on a side and a height of x cm; the volume will therefore be $V = x(12 - 2x)^2 = 4x(6 - x)^2$. Because both $x \geq 0$ and $12 - 2x \geq 0$, it follows that $x \leq 6$, so the domain of V is the closed interval $[0, 6]$. The function V is differentiable on the open interval $(0, 6)$, so the critical numbers occur where $V'(x) = 0$. Now,

$$V'(x) = 4x \cdot 2(6 - x)(-1) + 4(6 - x)^2 = (6 - x)(-8x + 24 - 4x) = (6 - x)(24 - 12x),$$

so the only critical number inside the open interval $(0, 6)$ is $x = 2$, where $V'(2) = 0$. Note that $x = 6$ is not in the open interval $(0, 6)$. Evaluating V at the endpoints of the interval $[0, 6]$ and at the critical number 2 yields

$$V(0) = 0, \quad V(2) = 128, \quad \text{and} \quad V(6) = 0.$$

The largest volume is therefore achieved when $x = 2$, and the box with the largest volume has a square base $12 - 2(2) = 8$ cm on a side and a height of 2 cm; that is, the box with the largest possible volume has dimensions 8 cm $\times$ 8 cm $\times$ 2 cm.

8. Let x denote the side length of the square cut from each corner of the base (see the diagram below). When the sides are turned up, the resulting box will have a rectangular base measuring $30 - 2x$ cm by $45 - 2x$ cm and a height of x cm; the volume will therefore be

$$V = x(30 - 2x)(45 - 2x) = 4x^3 - 150x^2 + 1350x.$$

To determine the domain of V , note that the length of each of the three sides of the box must be non-negative. This requires $x \geq 0$, $30 - 2x \geq 0$, and $45 - 2x \geq 0$. The solution of this set of three inequalities is $0 \leq x \leq 15$; therefore, the domain of V is the closed interval $[0, 15]$. The function V is differentiable on the open interval $(0, 15)$, so the critical numbers occur where $V'(x) = 0$. Now,

$$V'(x) = 12x^2 - 300x + 1350 = 6(2x^2 - 50x + 225),$$

so the only critical number inside the open interval $(0, 15)$ is

$$x = \frac{50 - \sqrt{50^2 - 4(2)(225)}}{4} = \frac{50 - \sqrt{700}}{4} = \frac{25 - 5\sqrt{7}}{2} \approx 5.886.$$

Note that

$$x = \frac{50 + \sqrt{50^2 - 4(2)(225)}}{4} = \frac{50 + \sqrt{700}}{4} = \frac{25 + 5\sqrt{7}}{2} \approx 19.114$$

is not in the domain of V . Evaluating V at the endpoints of the interval $[0, 15]$ and at the approximate critical number 5.886 yields

$$V(0) = 0, \quad V(5.886) \approx 3565.032, \quad \text{and} \quad V(15) = 0.$$

The largest volume is therefore achieved when $x \approx 5.886$, and the box with the largest volume has a rectangular base measuring approximately $30 - 2(5.886) = 18.228$ cm by $45 - 2(5.886) = 33.228$ cm and a height of approximately 5.886 cm; that is, the box with the largest possible volume has dimensions $18.228 \text{ cm} \times 33.228 \text{ cm} \times 5.886 \text{ cm}$.

9. Let s denote the side length of the square base and h denote the height of the open top box. The surface area A of the box is then

$$A = 4sh + s^2,$$

where the first term accounts for the area of the four vertical rectangular sides of the box and the second term accounts for the area of the base. Given that the box is to have a volume of 2000 cm^3 , s and h are related by the equation

$$s^2h = 2000 \quad \text{or} \quad h = \frac{2000}{s^2}.$$

Substituting for h in the area formula yields

$$A = \frac{8000}{s} + s^2.$$

The domain of A is the interval $(0, \infty)$. Now,

$$A'(s) = -\frac{8000}{s^2} + 2s = \frac{2(s^3 - 4000)}{s^2},$$

so the only critical number inside the open interval $(0, \infty)$ is $s = 10\sqrt[3]{4}$, where $A'(s) = 0$. Note that $s = 0$ is not in the domain of A . Using the Second Derivative Test,

$$A''(s) = \frac{16000}{s^3} + 2 \quad \text{so} \quad A''(10\sqrt[3]{4}) = 6 > 0$$

and A has a local minimum value at $10\sqrt[3]{4}$. Because $A''(s) > 0$ for all $s > 0$, the local minimum is also an absolute minimum. Therefore, the minimum amount of material is used to make the box when $s = 10\sqrt[3]{4}$ and

$$h = \frac{2000}{100\sqrt[3]{16}} = \frac{20\sqrt[3]{4}}{4} = 5\sqrt[3]{4}.$$

The box should have a square base measuring $10\sqrt[3]{4} \approx 15.874$ cm on a side and a height of $5\sqrt[3]{4} \approx 7.937$ cm; that is, the dimensions of the box using the minimum amount of material are

$$\boxed{10\sqrt[3]{4} \times 10\sqrt[3]{4} \times 5\sqrt[3]{4} \approx 15.874 \text{ cm} \times 15.874 \text{ cm} \times 7.937 \text{ cm}}.$$

10. Let s denote the side length of the square base and h denote the height of the closed top box. The surface area A of the box is then

$$A = 4sh + 2s^2,$$

where the first term accounts for the area of the four vertical rectangular sides of the box and the second term accounts for the area of the base and the top. Given that the box is to have a volume of 2000 cm^3 , s and h are related by the equation

$$s^2h = 2000 \quad \text{or} \quad h = \frac{2000}{s^2}.$$

Substituting for h in the area formula yields

$$A = \frac{8000}{s} + 2s^2.$$

The domain of A is the interval $(0, \infty)$. Now,

$$A'(s) = -\frac{8000}{s^2} + 4s = \frac{4(s^3 - 2000)}{s^2},$$

so the only critical number inside the open interval $(0, \infty)$ is $s = 10\sqrt[3]{2}$, where $A'(s) = 0$. Note that $s = 0$ is not in the domain of A . Using the Second Derivative Test,

$$A''(s) = \frac{16000}{s^3} + 4 \quad \text{so} \quad A''(10\sqrt[3]{2}) = 12 > 0$$

and A has a local minimum value at $10\sqrt[3]{2}$. Because $A''(s) > 0$ for all $s > 0$, the local minimum is also an absolute minimum. Therefore, the minimum amount of material is used to make the box when $s = 10\sqrt[3]{2}$ and

$$h = \frac{2000}{100\sqrt[3]{4}} = \frac{20\sqrt[3]{2}}{2} = 10\sqrt[3]{2}.$$

The box should have a square base measuring $10\sqrt[3]{2} \approx 12.599$ cm on a side and a height of $10\sqrt[3]{2} \approx 12.599$ cm; that is, the box should be a $\text{cube with side length } 10\sqrt[3]{2} \approx 12.599 \text{ cm}$.

11. Let r denote the radius and h the height of the cylindrical can. The cost C of the material needed to manufacture the can is

$$C = 2\pi r^2(20) + 2\pi rh(15) = 40\pi r^2 + 30\pi rh,$$

where the first term accounts for the cost of the top and bottom of the can and the second term accounts for the lateral surface area of the can. Given that the can is to have a capacity of the 10 m^3 , r and h are related by the equation

$$\pi r^2 h = 10 \quad \text{or} \quad h = \frac{10}{\pi r^2}.$$

Substituting for h in the cost formula yields

$$C = 40\pi r^2 + \frac{300}{r}.$$

The domain of C is the interval $(0, \infty)$. Now,

$$C'(r) = 80\pi r - \frac{300}{r^2},$$

so the only critical number inside the open interval $(0, \infty)$ is $r = \sqrt[3]{\frac{15}{4\pi}}$, where $C'(r) = 0$. Note that $r = 0$ is not in the domain of C . Using the Second Derivative Test,

$$C''(r) = 80\pi + \frac{600}{r^3} \quad \text{so} \quad C''\left(\sqrt[3]{\frac{15}{4\pi}}\right) = 240\pi > 0,$$

and C has a local minimum value at $\sqrt[3]{\frac{15}{4\pi}}$. Because $C''(r) > 0$ for all $r > 0$, the local minimum is also

an absolute minimum. Therefore, the minimum cost of material is achieved when $r = \sqrt[3]{\frac{15}{4\pi}}$ and

$$h = \frac{10}{\pi \sqrt[3]{\frac{225}{16\pi^2}}} = \frac{8}{3} \sqrt[3]{\frac{15}{4\pi}}.$$

The can should have a radius of $\sqrt[3]{\frac{15}{4\pi}} \approx 1.061$ m and a height of $\frac{8}{3} \sqrt[3]{\frac{15}{4\pi}} \approx 2.829$ m.

12. Let x denote the length of fencing used along the front and back of the rectangular plot and y denote the length of fencing used along the other two sides (see the diagram below). The cost C of the fencing is

$$C = x(20) + x(10) + 2y(10) = 30x + 20y.$$

Given that the plot of land enclosed by the fencing is to have an area of 60,000 m², x and y are related by the equation

$$xy = 60,000 \quad \text{or} \quad y = \frac{60,000}{x}.$$

Substituting for y in the cost equation yields

$$C = 30x + \frac{1,200,000}{x}.$$

The domain of C is the interval $(0, \infty)$. Now,

$$C'(x) = 30 - \frac{1,200,000}{x^2},$$

so the only critical number inside the open interval $(0, \infty)$ is $x = 200$, where $C'(x) = 0$. Note that neither $x = -200$ nor $x = 0$ is in the domain of C . Using the Second Derivative Test,

$$C''(x) = \frac{2,400,000}{x^3} \quad \text{so} \quad C''(200) = \frac{3}{10} > 0,$$

and C has a local minimum value at 200. Because $C''(x) > 0$ for all $x > 0$, the local minimum is also an absolute minimum. Therefore, the cost of the fencing is minimized when $x = 200$ and $y = 300$. The builder should purchase 200 m of the \$20 per meter fencing and

$$200 + 300 + 300 = 800 \text{ m of the } \$10 \text{ per meter fencing}$$

at a cost of

$$C = 30(200) + 20(300) = \$12,000.$$

13. Let x denote the number of \$1 increases in the rental price above the original \$18 per day price. The rental price is then $18 + x$ and the number of cars rented is $24 - x$ so the rental income I is

$$I = (18 + x)(24 - x) = 432 + 6x - x^2.$$

The domain of I is the closed interval $[0, 24]$. The function I is differentiable on the open interval $(0, 24)$, so the critical numbers occur where $I'(x) = 0$. Now,

$$I'(x) = 6 - 2x,$$

so $I'(x) = 0$ when $x = 3$. Evaluating I at the endpoints of the interval $[0, 24]$ and at the critical number 3 yields

$$I(0) = 432, \quad I(3) = 21^2 = 441, \quad \text{and} \quad I(24) = 0.$$

Rental income is therefore maximized when $x = 3$, meaning that the agency should charge $18 + 3 = \$21$ per day to maximize income.

14. Let x denote the number of members above 60 in the charter flight club. The number of members is then $60 + x$ and the yearly charge is $200 - 2x$ so the revenue R generated by the dues is

$$R = (60 + x)(200 - 2x) = 12000 + 80x - 2x^2.$$

The domain of R is the closed interval $[0, 100]$. The function R is differentiable on the open interval $(0, 100)$, so the critical numbers occur where $R'(x) = 0$. Now,

$$R'(x) = 80 - 4x,$$

so $R'(x) = 0$ when $x = 20$. Evaluating R at the endpoints of the interval $[0, 100]$ and at the critical number 20 yields

$$R(0) = 12000, \quad R(20) = 80(160) = 12800, \quad \text{and} \quad R(100) = 0.$$

Revenue is therefore maximized when $x = 20$, meaning that $60 + 20 = 80$ members maximizes revenue.

15. Because distance is non-negative, minimizing the square of the distance will produce the same result as minimizing the distance but does not require the use of square roots. Let D denote the square of the distance between an arbitrary point on the graph of the parabola $y = x^2$ and the point $\left(2, \frac{1}{2}\right)$. Then

$$\begin{aligned} D &= (x - 2)^2 + \left(y - \frac{1}{2}\right)^2 = (x - 2)^2 + \left(x^2 - \frac{1}{2}\right)^2 \\ &= x^2 - 4x + 4 + x^4 - x^2 + \frac{1}{4} \\ &= x^4 - 4x + \frac{17}{4}. \end{aligned}$$

The domain of D is all real numbers, and because D is differentiable everywhere, the critical numbers of D occur where $D'(x) = 0$. Now,

$$D'(x) = 4x^3 - 4 = 4(x - 1)(x^2 + x + 1),$$

so $x = 1$ is the only critical number. Using the Second Derivative Test,

$$D''(x) = 12x^2 \quad \text{so} \quad D''(1) = 12 > 0$$

and D has a local minimum value at 1. Because $D''(x) \geq 0$ for all x , the local minimum is also an absolute minimum. The point $(1, 1^2) = (1, 1)$ on the graph of the parabola $y = x^2$ is closest to the point $\left(2, \frac{1}{2}\right)$.

16. Because distance is non-negative, minimizing the square of the distance will produce the same result as minimizing the distance but does not require the use of square roots. Let D denote the square of the distance between an arbitrary point on the graph of the parabola $y = 2x^2$ and the point $(1, 4)$. Then

$$\begin{aligned} D &= (x-1)^2 + (y-4)^2 = (x-1)^2 + (2x^2-4)^2 \\ &= x^2 - 2x + 1 + 4x^4 - 16x^2 + 16 \\ &= 4x^4 - 15x^2 - 2x + 17. \end{aligned}$$

The domain of D is all real numbers, and because D is differentiable everywhere, the critical numbers of D occur where $D'(x) = 0$. Now,

$$D'(x) = 16x^3 - 30x - 2.$$

Using the computer algebra system *Maple*, the critical numbers are found to be $x \approx -1.335$, $x \approx -0.067$, and $x \approx 1.401$. Evaluating D at each of these values yields

$$D(-1.335) \approx 5.642, \quad D(-0.067) \approx 17.067, \quad \text{and} \quad D(1.401) \approx 0.166.$$

As

$$\lim_{x \rightarrow \pm\infty} D(x) = \infty,$$

it follows that D has an absolute minimum at approximately 1.401. The point $(1.401, 2 \cdot 1.401^2) \approx (1.401, 3.926)$ on the graph of the parabola $y = 2x^2$ is closest to the point $(1, 4)$.

17. Because distance is non-negative, minimizing the square of the distance will produce the same result as minimizing the distance but does not require the use of square roots. Let D denote the square of the distance between an arbitrary point on the graph of the parabola $y = 4 - x^2$ and the point $(6, 2)$. Then

$$\begin{aligned} D &= (x-6)^2 + (y-2)^2 = (x-6)^2 + (4-x^2-2)^2 \\ &= x^2 - 12x + 36 + 4 - 4x^2 + x^4 \\ &= x^4 - 3x^2 - 12x + 40. \end{aligned}$$

The domain of D is all real numbers, and because D is differentiable everywhere, the critical numbers of D occur where $D'(x) = 0$. Now,

$$D'(x) = 4x^3 - 6x - 12.$$

Using the computer algebra system *Maple*, the only critical number is $x \approx 1.784$. Using the Second Derivative Test,

$$D''(x) = 12x^2 - 6 \quad \text{so} \quad D''(1.784) \approx 32.192 > 0$$

and D has a local minimum value at 1.784. As

$$\lim_{x \rightarrow \pm\infty} D(x) = \infty,$$

it follows that the local minimum is also an absolute minimum. The point $(1.784, 4 - 1.784^2) \approx (1.784, 0.817)$ on the graph of the parabola $y = 4 - x^2$ is closest to the point $(6, 2)$.

18. Because distance is non-negative, minimizing the square of the distance will produce the same result as minimizing the distance but does not require the use of square roots. Let D denote the square of the distance between an arbitrary point on the graph of the parabola $y = \sqrt{x}$ and the point $(4, 0)$. Then

$$\begin{aligned} D &= (x-4)^2 + (y-0)^2 = (x-4)^2 + (\sqrt{x}-0)^2 \\ &= x^2 - 8x + 16 + x \\ &= x^2 - 7x + 16. \end{aligned}$$

The domain of D is all real numbers, and because D is differentiable everywhere, the critical numbers of D occur where $D'(x) = 0$. Now,

$$D'(x) = 2x - 7,$$

so $x = \frac{7}{2}$ is the only critical number. Using the Second Derivative Test,

$$D''(x) = 2 \quad \text{so} \quad D''\left(\frac{7}{2}\right) = 2 > 0$$

and D has a local minimum value at $\frac{7}{2}$. Because $D''(x) > 0$ for all x , the local minimum is also an absolute minimum. The point

$$\left(\frac{7}{2}, \sqrt{\frac{7}{2}}\right) = \left(\frac{7}{2}, \frac{\sqrt{14}}{2}\right)$$

on the graph of $y = \sqrt{x}$ is closest to the point $(4, 0)$.

19. Let x denote the traveling speed of a truck and let

$$C(x) = \left(\frac{1600}{x} + x\right)a + \frac{200}{x}b + c$$

be the cost associated with a 200-mile trip where a is the cost per gallon for gasoline, b is the hourly rate paid to the driver, and c is a commission paid to the driver. With a top speed of 75 mph, the domain of C is the interval $(0, 75]$. The critical numbers of C occur where $C'(x) = 0$ or where $C'(x)$ does not exist. Now,

$$C'(x) = \left(1 - \frac{1600}{x^2}\right)a - \frac{200}{x^2}b,$$

so $C'(x)$ is equal to zero when

$$x = \pm \sqrt{\frac{1600a + 200b}{a}}$$

and does not exist when $x = 0$. Of these numbers, only $\sqrt{\frac{1600a + 200b}{a}}$ lies inside the interval $(0, 75)$. Using the Second Derivative Test,

$$C''(x) = \frac{3200}{x^3}a + \frac{400}{x^3}b > 0$$

for all x in $(0, 75)$, so C has a local and an absolute minimum at

$$x = \sqrt{\frac{1600a + 200b}{a}}.$$

- (a) With $a = \$3.50$, $b = 0$, and $c = 0$, the speed that minimizes cost is

$$x = \sqrt{\frac{1600(3.50) + 200(0)}{3.50}} = \sqrt{\frac{5600}{3.50}} = \sqrt{1600} = \boxed{40 \text{ miles per hour}}.$$

(b) With $a = \$3.50$, $b = \$10.00$, and $c = \$500$, the speed that minimizes cost is

$$x = \sqrt{\frac{1600(3.50) + 200(10.00)}{3.50}} = \sqrt{\frac{7600}{3.50}} \approx \boxed{46.6 \text{ miles per hour}}.$$

(c) With $a = \$4.00$, $b = \$20.00$, and $c = 0$, the speed that minimizes cost is

$$x = \sqrt{\frac{1600(4.00) + 200(20.00)}{4.00}} = \sqrt{\frac{10400}{4.00}} = \sqrt{2600} \approx \boxed{51.0 \text{ miles per hour}}.$$

20. Using the diagram in the text, the distance from the house to the connection point along the road is $\sqrt{x^2 + 4}$ km and the distance from the connection point to the cable box is $5 - x$ km. The construction cost C is then given by

$$C(x) = 60\sqrt{x^2 + 4} + 50(5 - x),$$

and the domain is the closed interval $[0, 5]$. The critical numbers of C occur where $C'(x) = 0$ or where $C'(x)$ does not exist. Now,

$$C'(x) = 60 \cdot \frac{1}{2}(x^2 + 4)^{-1/2}(2x) - 50 = \frac{60x}{\sqrt{x^2 + 4}} - 50,$$

so $C'(x)$ exists everywhere and is equal to zero when

$$\begin{aligned} \frac{60x}{\sqrt{x^2 + 4}} - 50 &= 0 \\ 60x &= 50\sqrt{x^2 + 4} \\ 3600x^2 &= 2500(x^2 + 4) \\ x^2 &= \frac{100}{11} \\ x &= \frac{10\sqrt{11}}{11}. \end{aligned}$$

Note that $x = -\frac{10\sqrt{11}}{11}$ is not in the domain of C . Evaluating C at the endpoints of the interval $[0, 5]$ and at the critical number $\frac{10\sqrt{11}}{11}$ yields

$$C(0) = 120 + 250 = 370, \quad C\left(\frac{10\sqrt{11}}{11}\right) \approx 316.33, \quad \text{and} \quad C(5) = 60\sqrt{29} \approx 323.11,$$

so the minimum cost occurs when $x = \frac{10\sqrt{11}}{11}$. To minimize construction cost, the connection point

should be $\boxed{5 - \frac{10\sqrt{11}}{11} \approx 1.985 \text{ km}}$ along the road from the cable box.

21. (a) Let x denote the distance from the point on the road closest to house A to the point where the path from house A to house B meets the road. Then the length L of the path from house A to house B is

$$L = \sqrt{q^2 + x^2} + \sqrt{(p - x)^2 + r^2},$$

where the first term accounts for the distance from house A to the road and the second term accounts for the distance from the road to house B . The domain of this function is the closed interval $[0, p]$, and the critical numbers occur where $L'(x) = 0$. Now,

$$L'(x) = \frac{x}{\sqrt{q^2 + x^2}} - \frac{p - x}{\sqrt{(p - x)^2 + r^2}},$$

so $L'(x) = 0$ when

$$\begin{aligned}
 \frac{x}{\sqrt{q^2 + x^2}} &= \frac{p-x}{\sqrt{(p-x)^2 + r^2}} \\
 x^2[(p-x)^2 + r^2] &= (p-x)^2(q^2 + x^2) \\
 x^2 r^2 &= (p-x)^2 q^2 \\
 xr &= |p-x|q = (p-x)q \quad \text{because } p \geq x \\
 x &= \frac{pq}{q+r}.
 \end{aligned}$$

Evaluating L at the endpoints of the interval $[0, p]$ and at the critical number $\frac{pq}{q+r}$ yields

$$\begin{aligned}
 L(0) &= q + \sqrt{r^2 + p^2}, \\
 L\left(\frac{pq}{q+r}\right) &= \sqrt{q^2 + \left(\frac{pq}{q+r}\right)^2} + \sqrt{\left(p - \frac{pq}{q+r}\right)^2 + r^2} \\
 &= \sqrt{q^2 + \left(\frac{pq}{q+r}\right)^2} + \sqrt{\left(\frac{pr}{q+r}\right)^2 + r^2} \\
 &= \sqrt{\frac{q^2}{(q+r)^2}[(q+r)^2 + p^2]} + \sqrt{\frac{r^2}{(q+r)^2}[p^2 + (q+r)^2]} \\
 &= \frac{q}{q+r}\sqrt{p^2 + (q+r)^2} + \frac{r}{q+r}\sqrt{p^2 + (q+r)^2} = \sqrt{p^2 + (q+r)^2}, \quad \text{and} \\
 L(p) &= \sqrt{q^2 + p^2} + r.
 \end{aligned}$$

Because p , q , and r are all positive numbers,

$$q + \sqrt{r^2 + p^2} = \sqrt{q^2 + 2q\sqrt{r^2 + p^2} + r^2 + p^2} > \sqrt{q^2 + 2qr + r^2 + p^2} = \sqrt{(q+r)^2 + p^2},$$

and

$$\sqrt{q^2 + p^2} + r = \sqrt{q^2 + p^2 + 2r\sqrt{q^2 + p^2} + r^2} > \sqrt{q^2 + 2qr + r^2 + p^2} = \sqrt{(q+r)^2 + p^2}.$$

Therefore, the length of the shortest path that goes from house A to the road and then on to house B is $\boxed{\sqrt{(q+r)^2 + p^2}}$.

- (b) Following the hint, reflect the point B across the road to the point C (see the diagram below). Note that any path from A to C is equivalent to (has the same distance as) the path from A to B obtained by reflecting the portion of the path to the left of the road across to the right side of the road. Additionally, the shortest path from A to C is a straight line, and therefore has a distance equal to the hypotenuse of triangle ADC : $\sqrt{(q+r)^2 + p^2}$. Therefore, the length of the shortest path from A to the road and then on to B is $\boxed{\sqrt{(q+r)^2 + p^2}}$, matching the result from part (a).

22. Let x denote the distance along the shore from the point P to the point where the boat lands on the shore. Then the person rows a distance of $\sqrt{x^2 + 9}$ km and walks a distance of $12 - x$ km to reach the town. Taking into account the given rowing and walking speeds, the time T it takes to reach the town is

$$T = \frac{\sqrt{x^2 + 9}}{2.5} + \frac{12 - x}{4} = \frac{2\sqrt{x^2 + 9}}{5} + \frac{12 - x}{4}.$$

The domain of T is the closed interval $[0, 12]$, and the critical numbers occur where $T'(x) = 0$ or where $T'(x)$ does not exist. Now,

$$T'(x) = \frac{2x}{5\sqrt{x^2 + 9}} - \frac{1}{4},$$

so $T'(x)$ exists everywhere and is equal to zero when

$$\begin{aligned} \frac{2x}{5\sqrt{x^2 + 9}} &= \frac{1}{4} \\ 8x &= 5\sqrt{x^2 + 9} \\ 64x^2 &= 25(x^2 + 9) \\ x^2 &= \frac{225}{39} \\ x &= \frac{15\sqrt{39}}{39}. \end{aligned}$$

Note that $x = -\frac{15\sqrt{39}}{39}$ is not in the domain of T . Evaluating T at the endpoints of the interval $[0, 12]$ and at the critical number $\frac{15\sqrt{39}}{39}$ yields

$$T(0) = \frac{6}{5} + 3 = 4.2, \quad T\left(\frac{15\sqrt{39}}{39}\right) \approx 3.937, \quad \text{and} \quad T(12) = \frac{2\sqrt{153}}{5} \approx 4.948,$$

so the minimum occurs when $x = \frac{15\sqrt{39}}{39}$. To minimize the time needed to reach the town, the boat should land on shore $\boxed{\frac{15\sqrt{39}}{39} \approx 2.402 \text{ km from the point } P}.$

23. The shortest beam will simultaneously be in contact with the wall that is being supported, the 2-m high wall in the middle, and the ground. Let x and h be as shown in the diagram below. The length of the ladder is then

$$L = \sqrt{(x + 5)^2 + h^2}.$$

By similar triangles,

$$\frac{x}{2} = \frac{x + 5}{h} \quad \text{so} \quad h = \frac{2(x + 5)}{x}.$$

Substituting for h in the length formula yields

$$L = \sqrt{(x + 5)^2 + \left(\frac{2(x + 5)}{x}\right)^2} = \frac{x + 5}{x} \sqrt{x^2 + 4} = \left(1 + \frac{5}{x}\right) \sqrt{x^2 + 4}.$$

The domain of L is the interval $(0, \infty)$. Now,

$$L'(x) = \left(1 + \frac{5}{x}\right) \cdot \frac{x}{\sqrt{x^2 + 4}} + \sqrt{x^2 + 4} \cdot \left(-\frac{5}{x^2}\right) = \frac{x^3 + 5x^2 - 5x^2 - 20}{x^2\sqrt{x^2 + 4}} = \frac{x^3 - 20}{x^2\sqrt{x^2 + 4}},$$

so the only critical number inside the open interval $(0, \infty)$ is $x = \sqrt[3]{20}$, where $L'(x) = 0$. Note that $x = 0$ is not in the domain of L . Using the Second Derivative Test,

$$\begin{aligned} L''(x) &= \frac{x^2\sqrt{x^2+4} \cdot 3x^2 - (x^3-20) \cdot \left(\frac{x^3}{\sqrt{x^2+4}} + 2x\sqrt{x^2+4}\right)}{x^4(x^2+4)} \\ &= \frac{3x^4(x^2+4) - x^3(x^3-20) - 2x(x^3-20)(x^2+4)}{x^4(x^2+4)^{3/2}} \\ &= \frac{3x^6 + 12x^4 - x^6 + 20x^3 - 2x^6 - 8x^4 + 40x^3 + 160x}{x^4(x^2+4)^{3/2}} \\ &= \frac{4x^4 + 60x^3 + 160x}{x^4(x^2+4)^{3/2}} = \frac{4x^3 + 60x^2 + 160}{x^3(x^2+4)^{3/2}}, \end{aligned}$$

so $L''(x) > 0$ for all $x > 0$ and L has a local and absolute minimum at $\sqrt[3]{20}$. The length of the shortest beam that can be used to brace the wall is therefore

$$L = \left(1 + \frac{5}{\sqrt[3]{20}}\right) \sqrt{\sqrt[3]{400} + 4} \approx \boxed{9.582 \text{ meters}}.$$

The angle of elevation of the beam is

$$\tan^{-1} \frac{2}{\sqrt[3]{20}} \approx 0.635 \text{ rad} \approx \boxed{36.383^\circ}.$$

24. Place the center of the cross section of the log at the origin so that the outer edge of the log corresponds to the equation $x^2 + y^2 = R^2$. With this coordinate system, the width of the beam is $2x$ and the depth of the beam is $2y$ so the strength S of the beam is

$$S = k(2x)(2y)^3 = 16kxy^3,$$

where k is a positive constant of proportionality. Substituting $y = \sqrt{R^2 - x^2}$ into the strength formula yields

$$S = 16kx(R^2 - x^2)^{3/2}.$$

The domain of this function is the closed interval $[0, R]$. Now,

$$\begin{aligned} S'(x) &= 16kx \cdot \frac{3}{2}(R^2 - x^2)^{1/2}(-2x) + 16k(R^2 - x^2)^{3/2} \\ &= 16k\sqrt{R^2 - x^2}(R^2 - x^2 - 3x^2) = 16k\sqrt{R^2 - x^2}(R^2 - 4x^2), \end{aligned}$$

so the only critical number inside the open interval $(0, R)$ is $x = R/2$, where $S'(x) = 0$. Note that neither $x = -R$ nor $x = -R/2$ is in the domain of S , and $x = R$ is not inside the open interval $(0, R)$. Evaluating S at the endpoints of the interval $[0, R]$ and at the critical number $R/2$ yields

$$S(0) = 0, \quad S\left(\frac{R}{2}\right) = 16k \cdot \frac{R}{2} \cdot \frac{3R^3\sqrt{3}}{8} = 3kR^4\sqrt{3}, \quad \text{and} \quad S(R) = 0.$$

Therefore, S achieves its absolute maximum value when $x = R/2$ and

$$y = \sqrt{R^2 - \frac{R^2}{4}} = \frac{R\sqrt{3}}{2}.$$

The strongest beam that can be cut from a log whose cross section has the form of a circle of radius R has a width of R and a depth of $R\sqrt{3}$.

25. Using the hint (that is, choosing the width of the beam to be $2x$ and the depth of the beam to be $2y$) gives

$$S = k(2x)(2y)^2 = 8kxy^2,$$

where k is a positive constant of proportionality. Solve the equation of the cross section, $10x^2 + 9y^2 = 90$, for $y^2 = 10 - \frac{10}{9}x^2$ and then substitute this expression into the formula for S , to obtain

$$S = 8kx \left(10 - \frac{10}{9}x^2 \right) = 80kx - \frac{80}{9}kx^3.$$

The domain of this function is the closed interval $[0, 3]$, and the critical numbers occur where $S'(x) = 0$. Now,

$$S'(x) = 80k - \frac{80}{3}kx^2,$$

so the only critical number inside the open interval $(0, 3)$ is $x = \sqrt{3}$, where $S'(x) = 0$. Note that $x = -\sqrt{3}$ is not in the domain of S . Evaluating S at the endpoints of the interval $[0, 3]$ and at the critical number $\sqrt{3}$ yields

$$S(0) = 0, \quad S(\sqrt{3}) = 80k\sqrt{3} - 80k\frac{\sqrt{3}}{3} = \frac{160k\sqrt{3}}{3}, \quad \text{and} \quad S(3) = 0.$$

Therefore, S achieves its absolute maximum value when $x = \sqrt{3}$ and $y = \sqrt{10 - \frac{10}{3}} = \frac{2\sqrt{15}}{3}$. The strongest beam that can be cut from a log whose cross section has the form of the ellipse $10x^2 + 9y^2 = 90$ has a width of $2\sqrt{3}$ and a depth of $\frac{4\sqrt{15}}{3}$.

26. With the center of the cross section of the log at the origin, as implied by the outer edge of the log having the equation $b^2x^2 + a^2y^2 = a^2b^2$, the width of the beam is $2x$ and the depth of the beam is $2y$ so the strength S of the beam is

$$S = k(2x)(2y)^3 = 16kxy^3,$$

where k is a positive constant of proportionality. Substituting $y = \sqrt{b^2 - \frac{b^2}{a^2}x^2} = \frac{b}{a}\sqrt{a^2 - x^2}$ into the strength formula yields

$$S = \frac{16kb^3}{a^3}x(a^2 - x^2)^{3/2}.$$

The domain of this function is the closed interval $[0, a]$. Now,

$$\begin{aligned} S'(x) &= \frac{16b^3}{a^3}x \cdot \frac{3}{2}(a^2 - x^2)^{1/2}(-2x) + \frac{16b^3}{a^3}(a^2 - x^2)^{3/2} \\ &= \frac{16b^3}{a^3}\sqrt{a^2 - x^2}(a^2 - x^2 - 3x^2) = \frac{16b^3}{a^3}\sqrt{a^2 - x^2}(a^2 - 4x^2), \end{aligned}$$

so the only critical number inside the open interval $(0, a)$ is $x = a/2$, where $S'(x) = 0$. Note that neither $x = -a$ nor $x = -a/2$ is in the domain of S , and $x = a$ is not inside the open interval $(0, a)$. Evaluating S at the endpoints of the interval $[0, a]$ and at the critical number $a/2$ yields

$$S(0) = 0, \quad S\left(\frac{a}{2}\right) = \frac{16kb^3}{a^3} \cdot \frac{a}{2} \cdot \frac{3a^3\sqrt{3}}{8} = 3kab^3\sqrt{3}, \quad \text{and} \quad S(a) = 0.$$

Therefore, S achieves its absolute maximum value when $x = a/2$ and

$$y = \frac{b}{a} \sqrt{a^2 - \frac{a^2}{4}} = \frac{b\sqrt{3}}{2}.$$

The strongest beam that can be cut from a log whose cross section has the form of the ellipse $b^2x^2 + a^2y^2 = a^2b^2$ has a width of a and a depth of $b\sqrt{3}$.

27. Let x denote the number of cases produced and p denote the price of a case. Solve the equation

$$x = 1430 - \frac{11}{6}p \quad \text{for} \quad p = 780 - \frac{6}{11}x,$$

and then substitute for p in the formula

$$P = xp - 132x = x \left(780 - \frac{6}{11}x \right) - 132x = 648x - \frac{6}{11}x^2.$$

The domain for P is the closed interval $[0, 1100]$, and the critical numbers occur where $P'(x) = 0$. Now,

$$P'(x) = 648 - \frac{12}{11}x,$$

so $x = 594$ is the only critical number. Evaluating P at the endpoints of the interval $[0, 1100]$ and at the critical number 594 yields

$$P(0) = 0, \quad P(594) = 192,456, \quad \text{and} \quad P(1100) = 52,800.$$

Therefore, P achieves its absolute maximum when $x = 594$ and

$$p = 780 - \frac{6}{11}(594) = 456.$$

To maximize profit, the winemaker should produce 594 cases of wine and sell them for \$456 per case.

28. Let r denote the radius of the semicircular portion of the window (so that the width of the rectangular portion of the window is $2r$) and h denote the height of the rectangular portion of the window. The total area A of the window is then

$$A = 2rh + \frac{1}{2}\pi r^2.$$

Given that the perimeter of the window is to be 10 m, r and h are related by the equation

$$2r + 2h + \pi r = 10 \quad \text{or} \quad h = 5 - \left(1 + \frac{\pi}{2}\right)r.$$

Substituting for h in the area formula yields

$$A = 2r \left[5 - \left(1 + \frac{\pi}{2}\right)r \right] + \frac{1}{2}\pi r^2 = 10r - \left(2 + \frac{\pi}{2}\right)r^2.$$

In order for h to be non-negative, we must have

$$5 - \left(1 + \frac{\pi}{2}\right)r \geq 0 \quad \text{or} \quad r \leq \frac{10}{2 + \pi}.$$

The domain of A is therefore the closed interval $\left[0, \frac{10}{2 + \pi}\right]$. The critical numbers of A occur where $A'(r) = 0$. Now,

$$A'(r) = 10 - (4 + \pi)r,$$

so $r = \frac{10}{4+\pi}$ is the only critical number. Evaluating A at the endpoints of the interval $\left[0, \frac{10}{2+\pi}\right]$ and at the critical number $\frac{10}{4+\pi}$ yields

$$\begin{aligned} A(0) &= 0; \\ A\left(\frac{10}{4+\pi}\right) &= \left(2 + \frac{1}{2}\pi\right) \left(\frac{10}{4+\pi}\right)^2 \approx 7.001; \text{ and} \\ A\left(\frac{10}{2+\pi}\right) &= \frac{1}{2}\pi \left(\frac{10}{2+\pi}\right)^2 \approx 5.942. \end{aligned}$$

Therefore, A achieves its absolute maximum when $r = \frac{10}{4+\pi}$ and

$$h = 5 - \left(1 + \frac{\pi}{2}\right) \frac{10}{4+\pi} = 5 \frac{4+\pi - (2+\pi)}{4+\pi} = \frac{10}{4+\pi}.$$

The Norman window that admits the most light with a perimeter of 10 m therefore has a

$$\boxed{\text{width of } 2r = \frac{20}{4+\pi} \approx 2.800 \text{ m}} \text{ and a } \boxed{\text{height of } \frac{10}{4+\pi} \approx 1.400 \text{ m}}.$$

29. Maximizing the capacity of the trough will be accomplished by maximizing the cross-sectional area of the trough. Let θ denote the angle between the two sides of the V-shaped trough. The cross-sectional area A of the trough is then

$$A = \frac{1}{2}28^2 \sin \theta = 392 \sin \theta.$$

The domain of A is the closed interval $[0, \pi]$, and the critical numbers occur where $A'(\theta) = 0$. Now,

$$A'(\theta) = 392 \cos \theta,$$

so $\theta = \frac{\pi}{2}$ is the only critical number. Evaluating A at the endpoints of the interval $[0, \pi]$ and at the critical number $\frac{\pi}{2}$ yields

$$A(0) = 0, \quad A\left(\frac{\pi}{2}\right) = 392, \quad \text{and} \quad A(\pi) = 0.$$

Therefore, A achieves its absolute maximum when $\theta = \frac{\pi}{2}$, so the capacity of the trough is maximum

when the angle between the sides is $\boxed{\frac{\pi}{2}}$.

30. Maximizing the carrying capacity of the gutter will be accomplished by maximizing the cross-sectional area of the gutter. Let x be defined as shown in the diagram below. The cross section of the gutter is a trapezoid with bases of length 10 and $10+2x$ and height $\sqrt{100-x^2}$. The area A of the cross section is then

$$A = \frac{1}{2}(10 + 10 + 2x)\sqrt{100-x^2} = (10+x)\sqrt{100-x^2}.$$

The domain of A is the closed interval $[0, 10]$. Now,

$$\begin{aligned} A'(x) &= (10+x) \frac{-x}{\sqrt{100-x^2}} + \sqrt{100-x^2} = \frac{-10x - x^2 + 100 - x^2}{\sqrt{100-x^2}} \\ &= \frac{-2(x^2 + 5x - 50)}{\sqrt{100-x^2}} = -\frac{2(x+10)(x-5)}{\sqrt{100-x^2}} = -\frac{2(x-5)\sqrt{x+10}}{\sqrt{10-x}}, \end{aligned}$$

so the only critical number inside the open interval $(0, 10)$ is $x = 5$, where $A'(x) = 0$. Note that $x = -10$ is not in the domain of A , and $x = 10$ is not inside the open interval $(0, 10)$. Evaluating A at the endpoints of the interval $[0, 10]$ and at the critical number 5 yields

$$A(0) = 100, \quad A(5) = 75\sqrt{3} \approx 129.904, \quad \text{and} \quad A(10) = 0.$$

Therefore, A achieves its absolute maximum when $x = 5$, so the carrying capacity of the gutter is maximum when the opening across the top is $\boxed{10 + 2(5) = 20 \text{ cm}}$.

31. Let r denote the radius of the semicircular ceiling (so that the width of the floor is $2r$) and h denote the height of the vertical walls. Without loss of generality suppose that the floor and vertical walls cost one unit per square meter so that the ceiling costs three units per square meter. The cost C for each one-meter long section of the tunnel is then

$$C = 2h(1) + 2r(1) + \pi r(3) = 2h + 2r + 3\pi r,$$

where the first term accounts for the cost of the vertical walls, the second term accounts for the cost of the floor, and the final term accounts for the cost of the ceiling. Let A denote the fixed cross-sectional area of the tunnel, so that

$$A = 2rh + \frac{1}{2}\pi r^2 \quad \text{or} \quad h = \frac{A - \frac{1}{2}\pi r^2}{2r} = \frac{A}{2r} - \frac{\pi r}{4}.$$

Substituting for h in the cost formula yields

$$C = 2\left(\frac{A}{2r} - \frac{\pi r}{4}\right) + 2r + 3\pi r = \frac{A}{r} + \left(\frac{5\pi}{2} + 2\right)r.$$

In order for h to be non-negative, we must have

$$\frac{A}{2r} - \frac{\pi r}{4} \geq 0 \quad \text{or} \quad r \leq \sqrt{\frac{2A}{\pi}}.$$

The domain of C is therefore the interval $\left(0, \sqrt{\frac{2A}{\pi}}\right]$. Now,

$$C'(r) = -\frac{A}{r^2} + \left(\frac{5\pi}{2} + 2\right),$$

so the only critical number inside the open interval $\left(0, \sqrt{\frac{2A}{\pi}}\right)$ is $r = \sqrt{\frac{2A}{5\pi + 4}}$, where $C'(r) = 0$. Note that $r = 0$ is not in the domain of C . Using the Second Derivative Test,

$$C''(r) = \frac{2A}{r^3} > 0$$

for all $r > 0$. Therefore, C has both a local and an absolute minimum when $r = \sqrt{\frac{2A}{5\pi + 4}}$. Finally, the most economical ratio of the diameter of the semicircular cylinder to the height of the vertical walls is

$$\frac{2r}{h} = \frac{4r^2}{A - \frac{1}{2}\pi r^2} = \frac{4 \cdot \frac{2A}{5\pi + 4}}{A - \frac{1}{2}\pi \cdot \frac{2A}{5\pi + 4}} = \frac{\frac{8}{5\pi + 4}}{1 - \frac{\pi}{5\pi + 4}} = \frac{8}{4\pi + 4} = \boxed{\frac{2}{\pi + 1}}.$$

32. Let r denote the radius of the hemispherical dome (so that the radius of the right circular cylinder is also r) and h denote the height of the right circular cylinder. Without loss of generality suppose

that the cylindrical wall costs one unit per square meter so that the dome costs three units per square meter. The cost C for the construction of the observatory is then

$$C = 2\pi rh(1) + 2\pi r^2(3) = 2\pi rh + 6\pi r^2,$$

where the first term accounts for the cost of the cylindrical wall and the second term accounts for the cost of the dome. Let V denote the fixed volume of the observatory, so that

$$V = \frac{2}{3}\pi r^3 + \pi r^2 h \quad \text{or} \quad h = \frac{V - \frac{2}{3}\pi r^3}{\pi r^2} = \frac{V}{\pi r^2} - \frac{2}{3}r.$$

Substituting for h in the cost formula yields

$$C = 2\pi r \left(\frac{V}{\pi r^2} - \frac{2}{3}r \right) + 6\pi r^2 = \frac{2V}{r} + \frac{14}{3}\pi r^2.$$

In order for h to be non-negative, we must have

$$\frac{V}{\pi r^2} - \frac{2}{3}r \geq 0 \quad \text{or} \quad r \leq \sqrt[3]{\frac{3V}{2\pi}}.$$

The domain of C is therefore the interval $\left(0, \sqrt[3]{\frac{3V}{2\pi}}\right]$. Now,

$$C'(r) = -\frac{2V}{r^2} + \frac{28}{3}\pi r,$$

so the only critical number inside the open interval $\left(0, \sqrt[3]{\frac{3V}{2\pi}}\right)$ is $r = \sqrt[3]{\frac{3V}{14\pi}}$, where $C'(r) = 0$. Note that $r = 0$ is not in the domain of C . Using the Second Derivative Test,

$$C''(r) = \frac{4V}{r^3} + \frac{28\pi}{3} > 0$$

for all $r > 0$. Therefore, C has both a local and an absolute minimum when $r = \sqrt[3]{\frac{3V}{14\pi}}$ and

$$h = \frac{V - \frac{2}{3}\pi \cdot \frac{3V}{14\pi}}{\pi \sqrt[3]{\left(\frac{3V}{14\pi}\right)^2}} = \frac{\frac{6}{7}V}{\pi \sqrt[3]{\left(\frac{3V}{14\pi}\right)^2}} = \frac{\frac{6}{7}V \cdot \sqrt[3]{\frac{3V}{14\pi}}}{\pi \cdot \frac{3V}{14\pi}} = 4\sqrt[3]{\frac{3V}{14\pi}}.$$

The most economical dimensions for the observatory are

$$\boxed{\text{a radius of } \sqrt[3]{\frac{3V}{14\pi}} \text{ and a height of } 4\sqrt[3]{\frac{3V}{14\pi}}},$$

for a given volume V .

33. Let the weaker light source have intensity I^* and be located at $x = 0$. The other light source has intensity $8I^*$ and is located at $x = 6$. For $0 < x < 6$, the intensity of light I at location x is

$$I = \frac{kI^*}{x^2} + \frac{8kI^*}{(6-x)^2},$$

where k is the constant of proportionality in the inverse square law, the first term accounts for illumination from the weaker light source and the second term accounts for illumination from the stronger source. Now,

$$I'(x) = -\frac{2kI^*}{x^3} + \frac{16kI^*}{(6-x)^3},$$

so $I'(x)$ is equal to zero when

$$\begin{aligned}\frac{2kI^*}{x^3} &= \frac{16kI^*}{(6-x)^3} \\ (6-x)^3 &= 8x^3 \\ 6-x &= 2x \\ x &= 2.\end{aligned}$$

Note that neither $x = 0$ nor $x = 6$ are in the domain of I , so 2 is the only critical number. Using the Second Derivative Test,

$$I''(x) = \frac{6kI^*}{x^4} + \frac{48kI^*}{(6-x)^4} > 0$$

for all x inside the interval $(0, 6)$. Therefore, I has both a local and an absolute minimum when $x = 2$, so the point between the two light sources at which illumination is minimum is 2 meters from the weaker light source.

34. Let $C(t) = \frac{2t}{16+t^2}$, and consider the interval $[0, \infty)$. The critical numbers of C occur where $C'(t) = 0$. Now,

$$C'(t) = \frac{(16+t^2) \cdot 2 - 2t \cdot 2t}{(16+t^2)^2} = \frac{32-2t^2}{(16+t^2)^2},$$

so the only critical number inside the open interval $(0, \infty)$ is $t = 4$, where $C'(t) = 0$. Note that $t = -4$ is not in the domain of C . Using the Second Derivative Test,

$$\begin{aligned}C''(t) &= \frac{(16+t^2)^2 \cdot (-4t) - (32-2t^2) \cdot 2(16+t^2)(2t)}{(16+t^2)^4} \\ &= \frac{-64t - 4t^3 - 128t + 8t^3}{(16+t^2)^3} = \frac{4t^3 - 192t}{(16+t^2)^3},\end{aligned}$$

so

$$C''(4) = \frac{256 - 768}{32^3} = -\frac{1}{64} < 0$$

and C has a local maximum value at 4. The local maximum value is $C(4) = \frac{1}{4}$. Because

$$C(0) = 0 \quad \text{and} \quad \lim_{t \rightarrow \infty} C(t) = 0,$$

the local maximum is also an absolute maximum. Therefore, the concentration of the drug in the bloodstream is greatest 4 hours after injection.

35. Let x denote the side length of the square and r denote the radius of the circle made from the two pieces of wire. The length L of the wire is then

$$L = 4x + 2\pi r.$$

Given that the area enclosed by the two pieces of wire is to be 64 cm^2 , x and r are related by the equation

$$x^2 + \pi r^2 = 64 \quad \text{or} \quad x = \sqrt{64 - \pi r^2}.$$

In order to have x defined, we must have

$$\pi r^2 \leq 64 \quad \text{or} \quad r \leq \frac{8}{\sqrt{\pi}}.$$

Substituting for x in the length formula yields

$$L = 4\sqrt{64 - \pi r^2} + 2\pi r,$$

where the domain is the closed interval $\left[0, \frac{8}{\sqrt{\pi}}\right]$. Now,

$$L'(r) = 4 \frac{-\pi r}{\sqrt{64 - \pi r^2}} + 2\pi,$$

so the only critical number inside the open interval $\left(0, \frac{8}{\sqrt{\pi}}\right)$ occurs when

$$\begin{aligned} \frac{4\pi r}{\sqrt{64 - \pi r^2}} &= 2\pi \\ 2r &= \sqrt{64 - \pi r^2} \\ 4r^2 &= 64 - \pi r^2 \\ (4 + \pi)r^2 &= 64 \\ r &= \frac{8}{\sqrt{4 + \pi}}. \end{aligned}$$

Note that neither $r = -\frac{8}{\sqrt{\pi}}$ nor $r = -\frac{8}{\sqrt{4 + \pi}}$ is in the domain of L , and $r = \frac{8}{\sqrt{\pi}}$ is not inside the open interval $\left(0, \frac{8}{\sqrt{\pi}}\right)$. Evaluating L at the endpoints of the interval $\left[0, \frac{8}{\sqrt{\pi}}\right]$ and at the critical number $\frac{8}{\sqrt{4 + \pi}}$ yields

$$L(0) = 32, \quad L\left(\frac{8}{\sqrt{4 + \pi}}\right) = \frac{64 + 16\pi}{\sqrt{4 + \pi}} \approx 42.758, \quad \text{and} \quad L\left(\frac{8}{\sqrt{\pi}}\right) = 16\sqrt{\pi} \approx 28.359.$$

Therefore, the

minimum length of wire that can be used is approximately 28.359 cm,

and the

maximum length wire that can be used is approximately 42.758 cm.

36. Let s denote the side length of the equilateral triangle and r denote the radius of the circle made from the two pieces of wire. The length L of the wire is then

$$L = 3s + 2\pi r.$$

Given that the area enclosed by the two pieces of wire is to be 64 cm^2 , s and r are related by the equation

$$\frac{s^2\sqrt{3}}{4} + \pi r^2 = 64 \quad \text{or} \quad s = \frac{2}{\sqrt[4]{3}}\sqrt{64 - \pi r^2}.$$

In order to have s defined, we must have

$$\pi r^2 \leq 64 \quad \text{or} \quad r \leq \frac{8}{\sqrt{\pi}}.$$

Substituting for s in the length formula yields

$$L = 2\sqrt[4]{27}\sqrt{64 - \pi r^2} + 2\pi r,$$

where the domain is the closed interval $\left[0, \frac{8}{\sqrt{\pi}}\right]$. Now,

$$L'(r) = 2\sqrt[4]{27} \frac{-\pi r}{\sqrt{64 - \pi r^2}} + 2\pi,$$

so the only critical number inside the open interval $\left(0, \frac{8}{\sqrt{\pi}}\right)$ occurs when

$$\begin{aligned}\frac{2\sqrt[4]{27}\pi r}{\sqrt{64 - \pi r^2}} &= 2\pi \\ \sqrt[4]{27}r &= \sqrt{64 - \pi r^2} \\ 3\sqrt{3}r^2 &= 64 - \pi r^2 \\ (3\sqrt{3} + \pi)r^2 &= 64 \\ r &= \frac{8}{\sqrt{3\sqrt{3} + \pi}}.\end{aligned}$$

Note that neither $r = -\frac{8}{\sqrt{\pi}}$ nor $r = -\frac{8}{\sqrt{3\sqrt{3} + \pi}}$ is in the domain of L , and $r = \frac{8}{\sqrt{\pi}}$ is not inside the open interval $\left(0, \frac{8}{\sqrt{\pi}}\right)$. Evaluating L at the endpoints of the interval $\left[0, \frac{8}{\sqrt{\pi}}\right]$ and at the critical number $\frac{8}{\sqrt{3\sqrt{3} + \pi}}$ yields

$$\begin{aligned}L(0) &= 16\sqrt[4]{27} \approx 36.472, \\ L\left(\frac{8}{\sqrt{3\sqrt{3} + \pi}}\right) &= 2\sqrt[4]{27}\sqrt{64 - \pi \cdot \frac{64}{3\sqrt{3} + \pi}} + \frac{16\pi}{\sqrt{3\sqrt{3} + \pi}} \\ &= 16\sqrt[4]{27}\sqrt{\frac{3\sqrt{3}}{3\sqrt{3} + \pi}} + \frac{16\pi}{\sqrt{3\sqrt{3} + \pi}} = \frac{16\sqrt[4]{27} \cdot \sqrt[4]{27}}{\sqrt{3\sqrt{3} + \pi}} + \frac{16\pi}{\sqrt{3\sqrt{3} + \pi}} \\ &= \frac{48\sqrt{3} + 16\pi}{\sqrt{3\sqrt{3} + \pi}} \approx 46.200, \quad \text{and} \\ L\left(\frac{8}{\sqrt{\pi}}\right) &= 16\sqrt{\pi} \approx 28.359.\end{aligned}$$

Therefore, the

$$\boxed{\text{minimum length of wire that can be used is approximately 28.359 cm}},$$

and the

$$\boxed{\text{maximum length wire that can be used is approximately 46.200 cm}}.$$

37. Let x denote the length of wire used to make the square. Then the side length of the square is $x/4$, the length of wire used to make the circle is $35 - x$ and the radius of the resulting circle is $\frac{35 - x}{2\pi}$. The area A enclosed by the two figures is then

$$A = \left(\frac{x}{4}\right)^2 + \pi \left(\frac{35 - x}{2\pi}\right)^2 = \frac{x^2}{16} + \frac{(35 - x)^2}{4\pi}.$$

The domain of this function is the closed interval $[0, 35]$, and the critical numbers occur where $A'(x) = 0$. Now,

$$A'(x) = \frac{x}{8} - \frac{35 - x}{2\pi},$$

so $A'(x) = 0$ when

$$\begin{aligned}\frac{x}{8} &= \frac{35 - x}{2\pi} \\ 2\pi x &= 280 - 8x \\ x &= \frac{140}{4 + \pi}.\end{aligned}$$

Evaluating A at the endpoints of the interval $[0, 35]$ and at the critical number $\frac{140}{4 + \pi}$ yields

$$\begin{aligned} A(0) &= \frac{35^2}{4\pi} \approx 97.482; \\ A\left(\frac{140}{4 + \pi}\right) &= \frac{1}{16} \left(\frac{140}{4 + \pi}\right)^2 + \frac{1}{4\pi} \left(35 - \frac{140}{4 + \pi}\right)^2 \\ &= \frac{70^2}{4(4 + \pi)^2} + \frac{35^2\pi^2}{4\pi(4 + \pi)^2} = \frac{70^2 + 35^2\pi}{4(4 + \pi)^2} \approx 42.883; \text{ and} \\ A(35) &= \frac{35^2}{16} = 76.5625. \end{aligned}$$

- (a) To enclose the minimum area, the wire should be cut so that

$$\frac{140}{4 + \pi} \approx \boxed{19.603 \text{ cm}}$$

are used for the square and the remaining

$$35 - \frac{140}{4 + \pi} = \frac{35\pi}{4 + \pi} \approx \boxed{15.397 \text{ cm}}$$

are used for the circle.

- (b) To enclose the maximum area, the entire length of wire should be formed into a circle since this corresponds to choosing $x = 0$.
- (c) The figure below displays the graph of the area enclosed as a function of the length of the wire used to make the square. The absolute minimum occurs for x a little less than 20 cm, confirming the result of part (a); the absolute maximum occurs for $x = 0$, confirming the result of part (b).

38. Let x denote the length of wire use to make the equilateral triangle. Then the side length of the equilateral triangle is $x/3$, the length of wire used to make the circle is $35 - x$ and the radius of the resulting circle is $\frac{35 - x}{2\pi}$. The area A enclosed by the two figures is then

$$A = \left(\frac{x}{3}\right)^2 \frac{\sqrt{3}}{4} + \pi \left(\frac{35 - x}{2\pi}\right)^2 = \frac{x^2\sqrt{3}}{36} + \frac{(35 - x)^2}{4\pi}.$$

The domain of this function is the closed interval $[0, 35]$, and the critical numbers occur where $A'(x) = 0$. Now,

$$A'(x) = \frac{x\sqrt{3}}{18} - \frac{35 - x}{2\pi},$$

so $A'(x) = 0$ when

$$\begin{aligned}\frac{x\sqrt{3}}{18} &= \frac{35-x}{2\pi} \\ 2\pi\sqrt{3}x &= 630 - 18x \\ x &= \frac{315}{9 + \pi\sqrt{3}}.\end{aligned}$$

Evaluating A at the endpoints of the interval $[0, 35]$ and at the critical number $\frac{315}{9 + \pi\sqrt{3}}$ yields

$$\begin{aligned}A(0) &= \frac{35^2}{4\pi} \approx 97.482; \\ A\left(\frac{315}{9 + \pi\sqrt{3}}\right) &= \frac{\sqrt{3}}{36} \left(\frac{315}{9 + \pi\sqrt{3}}\right)^2 + \frac{1}{4\pi} \left(35 - \frac{315}{9 + \pi\sqrt{3}}\right)^2 \\ &= \frac{35^2 \cdot 9\sqrt{3}}{4(9 + \pi\sqrt{3})^2} + \frac{35^2 \cdot 3\pi^2}{4\pi(9 + \pi\sqrt{3})^2} = \frac{35^2(9\sqrt{3} + 3\pi)}{4(9 + \pi\sqrt{3})^2} \approx 36.371; \text{ and} \\ A(35) &= \frac{35^2\sqrt{3}}{36} \approx 58.938.\end{aligned}$$

- (a) To enclose the minimum area, the wire should be cut so that

$$\frac{315}{9 + \pi\sqrt{3}} \approx \boxed{21.812 \text{ cm}}$$

are used for the equilateral triangle and the remaining

$$35 - \frac{315}{9 + \pi\sqrt{3}} = \frac{35\pi\sqrt{3}}{9 + \pi\sqrt{3}} \approx \boxed{13.188 \text{ cm}}$$

are used for the circle.

- (b) To enclose the maximum area, the entire length of wire should be formed into a circle since this corresponds to choosing $x = 0$.
- (c) The figure below displays the graph of the area enclosed as a function of the length of the wire used to make the equilateral triangle. The absolute minimum occurs for x a little less than 22 cm, confirming the result of part (a); the absolute maximum occurs for $x = 0$, confirming the result of part (b).

39. Let r denote the radius and h the height of the cylindrical can. The surface area A is then

$$A = 2\pi r^2 + 2\pi rh,$$

where the first term accounts for the area of the top and bottom of the can and the second term accounts for the lateral surface area. Given that the volume of the can is fixed to be V , r and h are related by the equation

$$V = \pi r^2 h \quad \text{or} \quad h = \frac{V}{\pi r^2}.$$

Substituting for h in the area formula yields

$$A = 2\pi r^2 + 2\pi r \frac{V}{\pi r^2} = 2\pi r^2 + \frac{2V}{r}.$$

The domain for this function is the interval $(0, \infty)$. Now,

$$A'(r) = 4\pi r - \frac{2V}{r^2},$$

so the only critical number inside the open interval $(0, \infty)$ is $r = \sqrt[3]{\frac{V}{2\pi}}$, where $A'(r) = 0$. Note that $r = 0$ is not in the domain of A . Using the Second Derivative Test,

$$A''(r) = 4\pi + \frac{4V}{r^3} > 0$$

for all $r > 0$. Therefore, A has a local and an absolute minimum at $\sqrt[3]{\frac{V}{2\pi}}$. When $r = \sqrt[3]{\frac{V}{2\pi}}$,

$$h = \frac{V}{\pi \sqrt[3]{\left(\frac{V}{2\pi}\right)^2}} = \frac{V \sqrt[3]{\frac{V}{2\pi}}}{\pi \frac{V}{2\pi}} = 2 \sqrt[3]{\frac{V}{2\pi}} = 2r,$$

so the cylindrical container of fixed volume which uses the least material has a height that is twice its radius.

40. Let the point of tangency between the hypotenuse and the graph of $y = 3e^{-x}$ be $(x_0, 3e^{-x_0})$. The equation of the line tangent to the graph of $y = 3e^{-x}$ at x_0 is

$$y - 3e^{-x_0} = -3e^{-x_0}(x - x_0) \quad \text{or} \quad y = -3e^{-x_0}x + 3e^{-x_0}(x_0 + 1).$$

The y -intercept of this line is $3e^{-x_0}(x_0 + 1)$ and the x -intercept of this line is $x_0 + 1$ so the area of the triangle that has been created is

$$A = \frac{1}{2}(x_0 + 1) \cdot 3e^{-x_0}(x_0 + 1) = \frac{3}{2}(x_0 + 1)^2 e^{-x_0}.$$

The domain of this function is the interval $[0, \infty)$. Now,

$$A'(x_0) = -\frac{3}{2}(x_0 + 1)^2 e^{-x_0} + 3(x_0 + 1)e^{-x_0} = \frac{3}{2}(x_0 + 1)e^{-x_0}[2 - (x_0 + 1)] = \frac{3}{2}(1 - x_0^2)e^{-x_0},$$

so the only critical number inside the open interval $(0, \infty)$ is $x_0 = 1$, where $A'(x_0) = 0$. Note that $x_0 = -1$ is not in the domain of A . Using the Second Derivative Test,

$$A''(x_0) = -\frac{3}{2}(1 - x_0^2)e^{-x_0} - 3x_0e^{-x_0},$$

so $A''(1) = -3e^{-1} < 0$ and A has a local maximum at 1. The local maximum value is $A(1) = 6e^{-1} \approx 2.207$. Because $A(0) = \frac{3}{2}$ and

$$\lim_{x_0 \rightarrow \infty} A(t) = \lim_{x_0 \rightarrow \infty} \frac{\frac{3}{2}(x_0 + 1)^2}{e^{x_0}} = \lim_{x_0 \rightarrow \infty} \frac{3(x_0 + 1)}{e^{x_0}} = \lim_{x_0 \rightarrow \infty} \frac{3}{e^{x_0}} = 0,$$

the local maximum is also an absolute maximum. The triangle of largest area that has two sides along the positive coordinate axes and its hypotenuse tangent to the graph of $y = 3e^{-x}$ has vertices at the origin, $(2, 0)$ and $(0, 6e^{-1})$.

41. Let $(x, y) = (x, 9 - x^2)$ be the coordinates of the vertex of the rectangle that lies on the graph of the parabola. Then the width of the rectangle is x , the height is $9 - x^2$, and the area is

$$A = x(9 - x^2) = 9x - x^3.$$

The domain of this function is the closed interval $[0, 3]$, and the critical numbers occur where $A'(x) = 0$. Now,

$$A'(x) = 9 - 3x^2,$$

so the only critical number inside the open interval $(0, 3)$ is $x = \sqrt{3}$, where $A'(x) = 0$. Note that $x = -\sqrt{3}$ is not in the domain of A . Evaluating A at the endpoints of the interval $[0, 3]$ and at the critical number $\sqrt{3}$ yields

$$A(0) = 0, \quad A(\sqrt{3}) = 6\sqrt{3}, \quad \text{and} \quad A(3) = 0.$$

Therefore, A has an absolute maximum value of $6\sqrt{3}$; in other words, the largest area of a rectangle with one vertex on the parabola $y = 9 - x^2$, another at the origin, and the remaining two on the positive coordinate axes is $\boxed{6\sqrt{3} \text{ square units}}$.

42. Using the diagram in the text, if the slant height of the cone is 4, then the radius of the cone is $4 \sin \theta$, the height of the cone is $4 \cos \theta$, and the volume of the cone is

$$V = \frac{1}{3} \pi r^2 h = \frac{64\pi}{3} \sin^2 \theta \cos \theta = \frac{64\pi}{3} (\cos \theta - \cos^3 \theta).$$

The domain of this function is the closed interval $[0, \pi/2]$, and the critical numbers occur where $V'(\theta) = 0$. Now,

$$V'(\theta) = \frac{64\pi}{3} (3 \cos^2 \theta \sin \theta - \sin \theta) = \frac{64\pi}{3} \sin \theta (3 \cos^2 \theta - 1),$$

so the only value of θ inside the interval $(0, \pi/2)$ for which $V'(\theta) = 0$ is $\theta = \cos^{-1} \frac{\sqrt{3}}{3}$. Evaluating V at the endpoints of the interval $[0, \pi/2]$ and at the critical number $\cos^{-1} \frac{\sqrt{3}}{3}$ yields

$$V(0) = 0, \quad V\left(\cos^{-1} \frac{\sqrt{3}}{3}\right) = \frac{128\pi\sqrt{3}}{27}, \quad \text{and} \quad V(\pi/2) = 0.$$

Therefore, V has an absolute maximum at $\cos^{-1} \frac{\sqrt{3}}{3}$. Finally, the right circular cone having a slant height of 4 ft and maximum volume has

$$\boxed{\text{a radius of } \frac{4\sqrt{6}}{3} \text{ ft and a height of } \frac{4\sqrt{3}}{3} \text{ ft} .}$$

43. Let a and b be positive real numbers and let m denote the slope of a line through the point (a, b) .

- Case I: $m > 0$.

Let $m = b/a$. The line $\boxed{y = mx = bx/a}$ passes through the origin, so $x_0 = y_0 = 0$ and the distance between the points $(x_0, 0)$ and $(0, y_0)$ is zero, an absolute minimum.

- Case II: $m < 0$ so that $x_0 > 0$ and $y_0 > 0$.

The equation of the line of slope m which passes through the point (a, b) is

$$y - b = m(x - a) \quad \text{or} \quad y = mx + b - ma.$$

The y -intercept of this line is $y_0 = b - ma$ and the x -intercept is $x_0 = \frac{am - b}{m}$, so the distance D between the points $(x_0, 0)$ and $(0, y_0)$ is

$$D = \sqrt{\left(\frac{am - b}{m}\right)^2 + (b - ma)^2} = |b - ma| \sqrt{1 + \frac{1}{m^2}} = (b - ma) \sqrt{1 + \frac{1}{m^2}},$$

where the absolute value could be removed because $a > 0$, $b > 0$, and $m < 0$ so that $b - ma > 0$. The critical numbers of D occur where $D'(m) = 0$. Now,

$$D'(m) = (b - ma) \cdot \frac{-\frac{2}{m^3}}{2\sqrt{1 + \frac{1}{m^2}}} - a \sqrt{1 + \frac{1}{m^2}} = -\frac{1}{\sqrt{1 + \frac{1}{m^2}}} \left(\frac{b - ma}{m^3} + a + \frac{a}{m^2} \right),$$

so $D'(m) = 0$ when

$$\begin{aligned} \frac{b - ma}{m^3} &= -\left(a + \frac{a}{m^2}\right) \\ b - ma &= -am^3 - ma \\ m &= -\sqrt[3]{\frac{b}{a}}. \end{aligned}$$

As there is just the one critical number and

$$\lim_{m \rightarrow 0^-} D(m) = \infty \quad \text{and} \quad \lim_{m \rightarrow -\infty} D(m) = \infty,$$

D has an absolute minimum at $-\sqrt[3]{\frac{b}{a}}$. The line

$$y = -\sqrt[3]{\frac{b}{a}}x + b + a\sqrt[3]{\frac{b}{a}}$$

produces the minimum distance between the points $(x_0, 0)$ and $(0, y_0)$, where x_0 and y_0 are the x - and y -intercepts, respectively, of the line.

44. Let $v = \frac{\ln t}{t}$, and consider the domain $t \geq 1$. Now,

$$v'(t) = \frac{t \cdot \frac{1}{t} - \ln t}{t^2} = \frac{1 - \ln t}{t^2},$$

so the only critical number inside the open interval $(1, \infty)$ occurs when $1 - \ln t = 0$, or when $t = e$. Note that $t = 0$ is not in the domain of v . For $1 \leq t < e$, $v'(t) > 0$, while for $t > e$, $v'(t) < 0$. Therefore, v is increasing for $1 \leq t < e$ and decreasing for $t > e$. By the First Derivative Test, v has a local maximum at $t = e$. The local maximum value is $v(e) = \frac{1}{e}$. Because

$$v(1) = 0 \quad \text{and} \quad \lim_{t \rightarrow \infty} v(t) = \lim_{t \rightarrow \infty} \frac{\ln t}{t} = \lim_{t \rightarrow \infty} \frac{\frac{1}{t}}{1} = 0,$$

where L'Hôpital's Rule was used to evaluate the limit, it follows that v has an absolute maximum at $t = e$. The object attains its maximum velocity at $t = e \approx 2.782$ seconds.

45. Let

$$F = \frac{cmg}{c \sin \theta + \cos \theta},$$

where the domain is the closed interval $[0, \pi/2]$. The critical numbers of F occur where $F'(\theta) = 0$ or where $F'(\theta)$ does not exist. Now,

$$F'(\theta) = \frac{-cmg}{(c \sin \theta + \cos \theta)^2} \cdot (c \cos \theta - \sin \theta).$$

$F'(\theta)$ exists for each θ in the open interval $(0, \pi/2)$ and is equal to zero when

$$c \cos \theta - \sin \theta = 0 \quad \text{or} \quad \tan \theta = c.$$

Based on the diagram below, when $\tan \theta = c$,

$$\sin \theta = \frac{c}{\sqrt{c^2 + 1}} \quad \text{and} \quad \cos \theta = \frac{1}{\sqrt{c^2 + 1}},$$

so, evaluating F at the endpoints of the interval $[0, \pi/2]$ and at the critical number associated with $\tan \theta = c$ yields

$$F(0) = cmg, \quad F(\tan^{-1} c) = \frac{cmg}{\sqrt{c^2 + 1}}, \quad \text{and} \quad F\left(\frac{\pi}{2}\right) = mg.$$

Because

$$\frac{c}{\sqrt{c^2 + 1}} < c \quad \text{its follows that} \quad F(\tan^{-1} c) = mg \cdot \frac{c}{\sqrt{c^2 + 1}} < cmg = F(0),$$

and because

$$\frac{c}{\sqrt{c^2 + 1}} < 1 \quad \text{its follows that} \quad F(\tan^{-1} c) = mg \cdot \frac{c}{\sqrt{c^2 + 1}} < mg = F\left(\frac{\pi}{2}\right),$$

so F has an absolute minimum when $\tan \theta = c$.

46. Let $V = kx(a - x)$ where k is a positive constant. The domain of V is the closed interval $[0, a]$, and the critical numbers occur where $V'(x) = 0$. Now,

$$V'(x) = ak - 2kx = k(a - 2x),$$

so $x = a/2$ is the only critical number. Evaluating V at the endpoints of the interval $[0, a]$ and at the critical number $a/2$ yields

$$V(0) = 0, \quad V\left(\frac{a}{2}\right) = \frac{ka^2}{4}, \quad \text{and} \quad V(a) = 0.$$

Therefore, V has an absolute maximum when $x = a/2$. The reaction rate is maximum when $\boxed{x = a/2}$.

47. Let x denote the distance from the observer to the wall, and let the angles θ and ψ be as noted in the diagram below. Then

$$\tan \theta = \tan((\theta + \psi) - \psi) = \frac{\tan(\theta + \psi) - \tan \psi}{1 + \tan(\theta + \psi) \tan \psi} = \frac{\frac{7}{x} - \frac{3}{x}}{1 + \frac{7}{x} \cdot \frac{3}{x}} = \frac{4x}{x^2 + 21}$$

and

$$\theta = \tan^{-1} \left(\frac{4x}{x^2 + 21} \right).$$

The domain of this function is the interval $(0, \infty)$, and the critical numbers occur where $\theta'(x) = 0$. Now,

$$\begin{aligned}\theta'(x) &= \frac{1}{1 + \left(\frac{4x}{x^2+21}\right)^2} \cdot \frac{(x^2+21) \cdot 4 - 4x \cdot 2x}{(x^2+21)^2} \\ &= \frac{4x^2 + 84 - 8x^2}{(x^2+21)^2 + 16x^2} = 4 \frac{21 - x^2}{(x^2+21)^2 + 16x^2},\end{aligned}$$

so the only critical number inside the open interval $(0, \infty)$ is $x = \sqrt{21}$, where $\theta'(x) = 0$. Note that $x = -\sqrt{21}$ is not in the domain of θ . As there is just this one critical number and

$$\lim_{x \rightarrow 0^+} \theta(x) = 0 \quad \text{and} \quad \lim_{x \rightarrow \infty} \theta(x) = 0,$$

θ has an absolute maximum at $\sqrt{21}$. Therefore, to obtain the most favorable view of the picture, the observer should stand $\boxed{\sqrt{21} \approx 4.583 \text{ meters}}$ from the wall.

48. Let $v = kx^2 \ln \frac{1}{x} = -kx^2 \ln x$. The domain of this function is the interval $(0, \infty)$. Now,

$$v'(x) = -kx^2 \cdot \frac{1}{x} - 2kx \ln x = -kx(1 + 2 \ln x),$$

so the only critical number inside the open interval $(0, \infty)$ is $x = e^{-1/2}$, where $v'(x) = 0$. Note that $x = 0$ is not in the domain of v .

Suppose the constant k is greater than 0. Then for $0 \leq x < e^{-1/2}$, $v'(x) > 0$, while for $x > e^{-1/2}$, $v'(x) < 0$. Therefore, v is increasing for $0 \leq x < e^{-1/2}$ and decreasing for $x > e^{-1/2}$. By the First Derivative Test, v has a local maximum at $x = e^{-1/2}$. The local maximum value is

$$v(e^{-1/2}) = -ke^{-1} \left(-\frac{1}{2}\right) = \frac{k}{2e} > 0.$$

Because

$$\lim_{x \rightarrow 0^+} v(x) = \lim_{x \rightarrow 0^+} (-kx^2 \ln x) = -k \lim_{x \rightarrow 0^+} \frac{\ln x}{x^{-2}} = -k \lim_{x \rightarrow 0^+} \frac{\frac{1}{x}}{-2x^{-3}} = \frac{k}{2} \lim_{x \rightarrow 0^+} x^2 = 0$$

and

$$\lim_{x \rightarrow \infty} v(x) = \lim_{x \rightarrow \infty} (-kx^2 \ln x) = -\infty,$$

where L'Hôpital's Rule was used to evaluate the first limit, it follows that v has an absolute maximum at $\boxed{x = e^{-1/2}}$.

On the other hand, suppose that k is less than 0. Then

$$\lim_{x \rightarrow \infty} -kx^2 \ln x = \infty$$

and v does not have an absolute maximum value.

49. Let a , b , and c be positive constants and consider the function $f(x) = ae^{cx} + be^{-cx}$. Then

$$f'(x) = ace^{cx} - bce^{-cx},$$

and the only critical number occurs when

$$\begin{aligned} ace^{cx} &= bce^{-cx} \\ e^{2cx} &= \frac{b}{a} \\ x &= \frac{1}{2c} \ln \frac{b}{a}. \end{aligned}$$

Next,

$$f''(x) = ac^2e^{cx} + bc^2e^{-cx} \geq 0$$

for all x . Therefore, f achieves an absolute minimum value when $x = \frac{1}{2c} \ln \frac{b}{a}$, and that absolute minimum value is

$$f\left(\frac{1}{2c} \ln \frac{b}{a}\right) = ae^{\frac{1}{2} \ln \frac{b}{a}} + be^{-\frac{1}{2} \ln \frac{b}{a}} = a\sqrt{\frac{b}{a}} + b\sqrt{\frac{a}{b}} = 2\sqrt{ab}.$$

Challenge Problems

50. In order to find the length of the *longest* pipe that can be carried around the corner, we must find the *shortest* length from the right wall to the top wall touching the corner of the inside wall. Any pipe that does not fit in this shortest space cannot be carried around the corner, so an exact fit represents the longest possible pipe. Let θ be as defined in the diagram in the text, and let c_1 be the length of the pipe in the 1-m wide corridor and c_2 be the length of the pipe in the 8-m wide corridor. By the definitions of the sine and cosine functions,

$$c_1 = \frac{1}{\sin \theta} \quad \text{and} \quad c_2 = \frac{8}{\cos \theta},$$

so the total length L of the pipe is

$$L = \frac{1}{\sin \theta} + \frac{8}{\cos \theta}.$$

The domain of this function is the interval $(0, \pi/2)$, and the critical numbers occur where $L'(\theta) = 0$. Now,

$$L'(\theta) = -\frac{1}{\sin^2 \theta} \cdot \cos \theta + \frac{8}{\cos^2 \theta} \cdot \sin \theta = \frac{8 \sin^3 \theta - \cos^3 \theta}{\sin^2 \theta \cos^2 \theta},$$

so $L'(\theta) = 0$ when

$$\begin{aligned} 8 \sin^3 \theta &= \cos^3 \theta \\ \tan^3 \theta &= \frac{1}{8} \\ \theta &= \tan^{-1} \frac{1}{2}. \end{aligned}$$

As there is only the one critical number and $L \rightarrow \infty$ as $\theta \rightarrow 0^+$ and as $\theta \rightarrow \pi/2^-$, L has an absolute minimum when $\theta = \tan^{-1} \frac{1}{2}$. Based on the diagram below, when $\theta = \tan^{-1} \frac{1}{2}$,

$$\sin \theta = \frac{1}{\sqrt{5}} \quad \text{and} \quad \cos \theta = \frac{2}{\sqrt{5}},$$

so

$$L(\tan^{-1} 2) = \frac{1}{1/\sqrt{5}} + \frac{8}{2/\sqrt{5}} = \sqrt{5} + 4\sqrt{5} = 5\sqrt{5}.$$

The longest pipe that can be carried around the indicated corner is therefore $5\sqrt{5} \approx 11.180$ meters long.

51. Based on the diagram in the text,

$$\cos \theta = \frac{20}{s} \quad \text{so} \quad s = \frac{20}{\cos \theta}$$

and

$$I = \frac{\sin \theta}{s} = \frac{\sin \theta \cos \theta}{20} = \frac{\sin(2\theta)}{40}.$$

The domain of this function is the interval $[0, \pi/2)$. Note that s is undefined for $\theta = \pi/2$, so this number cannot be included in the domain. Now,

$$I'(\theta) = \frac{1}{20} \cos(2\theta),$$

so $I'(\theta) = 0$ on the open interval $(0, \pi/2)$ when $\theta = \pi/4$. Because

$$I(0) = 0, \quad I\left(\frac{\pi}{4}\right) = \frac{1}{40}, \quad \text{and} \quad \lim_{\theta \rightarrow \pi/2^-} I(\theta) = 0,$$

it follows that I has an absolute maximum when $\theta = \pi/4$. If h is the height of the lamp, then

$$\tan \theta = \frac{h}{20} \quad \text{so} \quad h = 20 \tan \theta.$$

For maximum illumination on the walk, the height of the lamp should be

$$h = 20 \tan \frac{\pi}{4} = \boxed{20 \text{ ft}}.$$

52. Let $y = f(x) = e^{-x^2}$. Then

$$\begin{aligned} f'(x) &= -2xe^{-x^2}; \text{ and} \\ f''(x) &= 4x^2e^{-x^2} - 2e^{-x^2} = 2(2x^2 - 1)e^{-x^2}, \end{aligned}$$

so $f''(x) = 0$ at $x = \pm \frac{\sqrt{2}}{2}$. Use these numbers to divide the number line into three intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, -\frac{\sqrt{2}}{2})$	+	f is concave up on $(-\infty, -\frac{\sqrt{2}}{2})$
$(-\frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2})$	-	f is concave down on $(-\frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2})$
$(\frac{\sqrt{2}}{2}, \infty)$	+	f is concave up on $(\frac{\sqrt{2}}{2}, \infty)$

The concavity of f changes at $\pm \frac{\sqrt{2}}{2}$, so the points $\left(-\frac{\sqrt{2}}{2}, e^{-1/2}\right)$ and $\left(\frac{\sqrt{2}}{2}, e^{-1/2}\right)$ are points of inflection.

Now, let (x, e^{-x^2}) and $(-x, e^{-x^2})$ be the coordinates of the upper vertices of the inscribed rectangle, where $x > 0$. The area A of the rectangle is then

$$A = 2xe^{-x^2}.$$

The critical numbers of A occur where $A'(x) = 0$. Next,

$$A'(x) = -4x^2e^{-x^2} + 2e^{-x^2} = -2(2x^2 - 1)e^{-x^2},$$

so $A'(x) = 0$ when $x = \frac{\sqrt{2}}{2}$. Note that $x = -\frac{\sqrt{2}}{2}$ is not in the domain of A . As

$$A\left(\frac{\sqrt{2}}{2}\right) = \sqrt{2}e^{-1/2} > 0$$

and

$$\lim_{x \rightarrow 0^+} A(x) = 0, \quad \text{and} \quad \lim_{x \rightarrow \infty} A(x) = \lim_{x \rightarrow \infty} \frac{2x}{e^{x^2}} = \lim_{x \rightarrow \infty} \frac{1}{xe^{x^2}} = 0,$$

A has an absolute maximum when $x = \frac{\sqrt{2}}{2}$. Observe that this is the x -coordinate of one of the points of inflection of y , so the rectangle of largest area that can be inscribed under the graph of $y = e^{-x^2}$ has two of its vertices at the points of inflection of y .

53. Because distance is non-negative, minimizing the square of the distance will produce the same result as minimizing the distance but does not require the use of square roots. Let D denote the square of the distance between an arbitrary point (x, y) on the graph of $y = e^{-x/2}$ and the point $(1, 8)$. Then

$$D = (x - 1)^2 + (y - 8)^2 = (x - 1)^2 + (e^{-x/2} - 8)^2.$$

The domain of D is all real numbers, and because D is differentiable everywhere, the critical numbers of D occur where $D'(x) = 0$. Now,

$$D'(x) = 2(x - 1) + 2(e^{-x/2} - 8) \cdot \left(-\frac{1}{2}e^{-x/2}\right) = 2(x - 1) - e^{-x/2}(e^{-x/2} - 8).$$

Using the computer algebra system *Maple*, the only critical number is $x \approx -3.758$. As

$$\lim_{x \rightarrow \pm\infty} D(x) = \infty,$$

it follows that D has an absolute minimum at approximately -3.758 . The point $\boxed{(-3.758, e^{1.879}) \approx (-3.758, 6.547)}$ on the graph of $y = e^{-x/2}$ is closest to the point $(1, 8)$.

4.8: Antiderivatives; Differential Equations

Concepts and Vocabulary

1. A function F is called an **antiderivative** of a function f if $F' = f$.
2. **True**. If F is an antiderivative of f , then $F(x) + C$, where C is a constant, is also an antiderivative of f .
3. All the antiderivatives of $y = x^{-1}$ are $\ln|x| + C$, where C is a constant.
4. **True**. An antiderivative of $\sin x$ is $-\cos x + \pi$ because $\frac{d}{dx}(-\cos x + \pi) = \sin x$.
5. **False**. The general solution of a differential equation $\frac{dy}{dx} = f(x)$ consists of all the antiderivatives of $f(x)$.
6. **True**. Free fall is an example of motion with constant acceleration.
7. **True**. To find a particular solution of a differential equation $\frac{dy}{dx} = f(x)$, we need a boundary condition.
8. **True**. If F_1 and F_2 are both antiderivatives of a function f on an interval I , then $F_1 - F_2 = C$, a constant, on the interval I .

Skill Building

9. All antiderivatives of the function $f(x) = 2$ are $F(x) = 2x + C$, where C is a constant.
10. All antiderivatives of the function $f(x) = \frac{1}{2}$ are $F(x) = \frac{1}{2}x + C$, where C is a constant.
11. Using the Constant Multiple Rule, all antiderivatives of the function $f(x) = 4x^5$ are

$$F(x) = 4 \cdot \frac{x^{5+1}}{5+1} + C = \frac{2}{3}x^6 + C,$$

where C is a constant.

12. All antiderivatives of the function $f(x) = x$ are

$$F(x) = \frac{x^{1+1}}{1+1} + C = \frac{1}{2}x^2 + C,$$

where C is a constant.

13. Using the Constant Multiple Rule, all antiderivatives of the function $f(x) = 5x^{3/2}$ are

$$F(x) = 5 \cdot \frac{x^{3/2+1}}{3/2+1} + C = 2x^{5/2} + C,$$

where C is a constant.

14. Using the Sum Rule, all antiderivatives of the function $f(x) = x^{5/2} + 2$ are

$$F(x) = \frac{x^{5/2+1}}{5/2+1} + 2x + C = \frac{2}{7}x^{7/2} + 2x + C,$$

where C is a constant.

15. Using the Constant Multiple Rule, all antiderivatives of the function $f(x) = 2x^{-2}$ are

$$F(x) = 2 \cdot \frac{x^{-2+1}}{-2+1} + C = -2x^{-1} + C = \boxed{-\frac{2}{x} + C},$$

where C is a constant.

16. Using the Constant Multiple Rule, all antiderivatives of the function $f(x) = 3x^{-3}$ are

$$F(x) = 3 \cdot \frac{x^{-3+1}}{-3+1} + C = \boxed{-\frac{3}{2}x^{-2} + C},$$

where C is a constant.

17. All antiderivatives of the function $f(x) = \sqrt{x} = x^{1/2}$ are

$$F(x) = \frac{x^{1/2+1}}{1/2+1} + C = \boxed{\frac{2}{3}x^{3/2} + C},$$

where C is a constant.

18. All antiderivatives of the function $f(x) = \frac{1}{\sqrt{x}} = x^{-1/2}$ are

$$F(x) = \frac{x^{-1/2+1}}{-1/2+1} + C = 2x^{1/2} + C = \boxed{2\sqrt{x} + C},$$

where C is a constant.

19. Using the Sum Rule and the Constant Multiple Rule, all antiderivatives of the function $f(x) = 4x^3 - 3x^2 + 1$ are

$$F(x) = 4 \cdot \frac{x^{3+1}}{3+1} - 3 \cdot \frac{x^{2+1}}{2+1} + x + C = \boxed{x^4 - x^3 + x + C},$$

where C is a constant.

20. Using the Sum Rule, all antiderivatives of the function $f(x) = x^2 - x$ are

$$F(x) = \frac{x^{2+1}}{2+1} - \frac{x^{1+1}}{1+1} + C = \boxed{\frac{1}{3}x^3 - \frac{1}{2}x^2 + C},$$

where C is a constant.

21. Expand

$$(2 - 3x)^2 \quad \text{as} \quad 9x^2 - 12x + 4.$$

Then, using the Sum Rule and the Constant Multiple Rule, all antiderivatives of the function $f(x) = (2 - 3x)^2 = 9x^2 - 12x + 4$ are

$$F(x) = 9 \cdot \frac{x^{2+1}}{2+1} - 12 \cdot \frac{x^{1+1}}{1+1} + 4x + C = \boxed{3x^3 - 6x^2 + 4x + C},$$

where C is a constant.

22. Expand

$$(3x - 1)^2 \quad \text{as} \quad 9x^2 - 6x + 1.$$

Then, using the Sum Rule and the Constant Multiple Rule, all antiderivatives of the function $f(x) = (3x - 1)^2 = 9x^2 - 6x + 1$ are

$$F(x) = 9 \cdot \frac{x^{2+1}}{2+1} - 6 \cdot \frac{x^{1+1}}{1+1} + x + C = \boxed{3x^3 - 3x^2 + x + C},$$

where C is a constant.

23. Rewrite

$$\frac{3x-2}{x} \quad \text{as} \quad \frac{3x}{x} - \frac{2}{x} = 3 - \frac{2}{x} = 3 - 2x^{-1}.$$

Then, using the Sum Rule and the Constant Multiple Rule, all antiderivatives of the function $f(x) = \frac{3x-2}{x} = 3 - 2x^{-1}$ are

$$F(x) = \boxed{3x - 2 \ln |x| + C},$$

where C is a constant.

24. Rewrite

$$\frac{4x^{3/2}-1}{x} \quad \text{as} \quad \frac{4x^{3/2}}{x} - \frac{1}{x} = 4x^{1/2} - x^{-1}.$$

Then, using the Sum Rule and the Constant Multiple Rule, all antiderivatives of the function $f(x) = \frac{4x^{3/2}-1}{x} = 4x^{1/2} - x^{-1}$ are

$$F(x) = 4 \cdot \frac{x^{1/2+1}}{1/2+1} - \ln |x| + C = \boxed{\frac{8}{3}x^{3/2} - \ln |x| + C},$$

where C is a constant.

25. Using the Sum Rule and the Constant Multiple Rule, all antiderivatives of the function $f(x) = 2x - 3 \cos x$ are

$$F(x) = 2 \cdot \frac{x^{1+1}}{1+1} - 3 \cdot \sin x + C = \boxed{x^2 - 3 \sin x + C},$$

where C is a constant.

26. Using the Sum Rule and the Constant Multiple Rule, all antiderivatives of the function $f(x) = 2 \sin x - \cos x$ are

$$F(x) = 2 \cdot (-\cos x) - \sin x + C = \boxed{-2 \cos x - \sin x + C},$$

where C is a constant.

27. Using the Sum Rule and the Constant Multiple Rule, all antiderivatives of the function $f(x) = 4e^x + x$ are

$$F(x) = 4 \cdot e^x + \frac{x^{1+1}}{1+1} + C = \boxed{4e^x + \frac{1}{2}x^2 + C},$$

where C is a constant.

28. Because

$$\frac{d}{dx}e^{-x} = e^{-x} \cdot (-1) = -e^{-x},$$

it follows that

$$\frac{d}{dx}(-e^{-x}) = e^{-x},$$

so $-e^{-x}$ is an antiderivative of the function e^{-x} . Using the Sum Rule, all antiderivatives of the function $f(x) = e^{-x} + \sec^2 x$ are

$$F(x) = \boxed{-e^{-x} + \tan x + C},$$

where C is a constant.

29. Using the Constant Multiple Rule, all antiderivatives of the function $f(x) = \frac{7}{1+x^2}$ are

$$F(x) = 7 \cdot \tan^{-1} x + C = \boxed{7 \tan^{-1} x + C},$$

where C is a constant.

30. Using the Sum Rule and the Constant Multiple Rule, all antiderivatives of the function $f(x) = x + \frac{10}{\sqrt{1-x^2}}$ are

$$F(x) = \frac{x^{1+1}}{1+1} + 10 \cdot \sin^{-1} x + C = \boxed{\frac{1}{2}x^2 + 10 \sin^{-1} x + C},$$

where C is a constant.

31. The general solution of the differential equation $\frac{dy}{dx} = 3x^2 - 2x + 1$ is

$$y = 3 \cdot \frac{x^{2+1}}{2+1} - 2 \cdot \frac{x^{1+1}}{1+1} + x + C = x^3 - x^2 + x + C,$$

where C is a constant. Applying the boundary condition that when $x = 2$, then $y = 1$ yields

$$1 = 2^3 - 2^2 + 2 + C = 6 + C,$$

so that $C = -5$. The particular solution of the differential equation with the boundary condition that when $x = 2$, then $y = 1$, is therefore

$$\boxed{y = x^3 - x^2 + x - 5}.$$

32. The general solution of the differential equation $\frac{dv}{dt} = 3t^2 - 2t + 1$ is

$$v = 3 \cdot \frac{t^{2+1}}{2+1} - 2 \cdot \frac{t^{1+1}}{1+1} + t + C = t^3 - t^2 + t + C,$$

where C is a constant. Applying the boundary condition that when $t = 1$, then $v = 5$ yields

$$5 = 1^3 - 1^2 + 1 + C = 1 + C,$$

so that $C = 4$. The particular solution of the differential equation with the boundary condition that when $t = 1$, then $v = 5$, is therefore

$$\boxed{v = t^3 - t^2 + t + 4}.$$

33. The general solution of the differential equation

$$\frac{dy}{dx} = x^{1/3} + x\sqrt{x} - 2 = x^{1/3} + x^{3/2} - 2$$

is

$$y = \frac{x^{1/3+1}}{1/3+1} + \frac{x^{3/2+1}}{3/2+1} - 2x + C = \frac{3}{4}x^{4/3} + \frac{2}{5}x^{5/2} - 2x + C,$$

where C is a constant. Applying the boundary condition that when $x = 1$, then $y = 2$ yields

$$2 = \frac{3}{4}1^{4/3} + \frac{2}{5}1^{5/2} - 2(1) + C = \frac{3}{4} + \frac{2}{5} - 2 + C = -\frac{17}{20} + C,$$

so that $C = \frac{57}{20}$. The particular solution of the differential equation with the boundary condition that when $x = 1$, then $y = 2$, is therefore

$$\boxed{y = \frac{3}{4}x^{4/3} + \frac{2}{5}x^{5/2} - 2x + \frac{57}{20}}.$$

34. The general solution of the differential equation $s'(t) = t^4 + 4t^3 - 5$ is

$$s(t) = \frac{t^{4+1}}{4+1} + 4 \cdot \frac{t^{3+1}}{3+1} - 5t + C = \frac{1}{5}t^5 + t^4 - 5t + C,$$

where C is a constant. Applying the boundary condition that when $t = 2$, then $s(2) = 5$ yields

$$5 = \frac{1}{5}2^5 + 2^4 - 5(2) + C = \frac{32}{5} + 16 - 10 + C = \frac{62}{5} + C,$$

so that $C = -\frac{37}{5}$. The particular solution of the differential equation with the boundary condition that when $t = 2$, then $s(2) = 5$, is therefore

$$\boxed{s(t) = \frac{1}{5}t^5 + t^4 - 5t - \frac{37}{5}}.$$

35. The general solution of the differential equation

$$\frac{ds}{dt} = t^3 + \frac{1}{t^2} = t^3 + t^{-2}$$

is

$$s = \frac{t^{3+1}}{3+1} + \frac{t^{-2+1}}{-2+1} + C = \frac{1}{4}t^4 - t^{-1} + C = \frac{1}{4}t^4 - \frac{1}{t} + C,$$

where C is a constant. Applying the boundary condition that when $t = 1$, then $s = 2$ yields

$$2 = \frac{1}{4}1^4 - \frac{1}{1} + C = \frac{1}{4} - 1 + C = -\frac{3}{4} + C,$$

so that $C = \frac{11}{4}$. The particular solution of the differential equation with the boundary condition that when $t = 1$, then $s = 2$, is therefore

$$\boxed{s = \frac{1}{4}t^4 - \frac{1}{t} + \frac{11}{4}}.$$

36. The general solution of the differential equation

$$\frac{dy}{dx} = \sqrt{x} - x\sqrt{x} + 1 = x^{1/2} - x^{3/2} + 1$$

is

$$y = \frac{x^{1/2+1}}{1/2+1} - \frac{x^{3/2+1}}{3/2+1} + x + C = \frac{2}{3}x^{3/2} - \frac{2}{5}x^{5/2} + x + C,$$

where C is a constant. Applying the boundary condition that when $x = 1$, then $y = 0$ yields

$$0 = \frac{2}{3}1^{3/2} - \frac{2}{5}1^{5/2} + 1 + C = \frac{2}{3} - \frac{2}{5} + 1 + C = \frac{19}{15} + C,$$

so that $C = -\frac{19}{15}$. The particular solution of the differential equation with the boundary condition that when $x = 1$, then $y = 0$, is therefore

$$\boxed{y = \frac{2}{3}x^{3/2} - \frac{2}{5}x^{5/2} + x - \frac{19}{15}}.$$

37. The general solution of the differential equation $f'(x) = x - 2 \sin x$ is

$$f(x) = \frac{x^{1+1}}{1+1} - 2 \cdot (-\cos x) + C = \frac{1}{2}x^2 + 2 \cos x + C,$$

where C is a constant. Applying the boundary condition that when $x = \pi$, then $f(\pi) = 0$ yields

$$0 = \frac{1}{2}\pi^2 + 2 \cos \pi + C = \frac{1}{2}\pi^2 - 2 + C,$$

so that $C = 2 - \frac{1}{2}\pi^2$. The particular solution of the differential equation with the boundary condition that when $x = \pi$, then $f(\pi) = 0$, is therefore

$$f(x) = \frac{1}{2}x^2 + 2 \cos x + 2 - \frac{1}{2}\pi^2.$$

38. The general solution of the differential equation $\frac{dy}{dx} = x^2 - 2 \sin x$ is

$$y = \frac{x^{2+1}}{2+1} - 2 \cdot (-\cos x) + C = \frac{1}{3}x^3 + 2 \cos x + C,$$

where C is a constant. Applying the boundary condition that when $x = \pi$, then $y = 0$ yields

$$0 = \frac{1}{3}\pi^3 + 2 \cos \pi + C = \frac{1}{3}\pi^3 - 2 + C,$$

so that $C = 2 - \frac{1}{3}\pi^3$. The particular solution of the differential equation with the boundary condition that when $x = \pi$, then $y = 0$, is therefore

$$y = \frac{1}{3}x^3 + 2 \cos x + 2 - \frac{1}{3}\pi^3.$$

39. All the antiderivatives of $\frac{d^2y}{dx^2} = e^x$ are

$$\frac{dy}{dx} = e^x + C_1,$$

and all the antiderivatives of $\frac{dy}{dx} = e^x + C_1$ are

$$y = e^x + C_1x + C_2,$$

where C_1 and C_2 are constants. Applying the boundary condition that when $x = 0$, then $y = 2$ yields

$$2 = e^0 + C_1(0) + C_2 = 1 + C_2,$$

so that $C_2 = 1$. Next, applying the boundary condition that when $x = 1$, then $y = e$ yields

$$e = e^1 + C_1(1) + 1 = e + 1 + C_1,$$

so that $C_1 = -1$. The particular solution of the differential equation with the given boundary conditions is therefore

$$y = e^x - x + 1.$$

40. All the antiderivatives of $f''(\theta) = \sin \theta + \cos \theta$ are

$$f'(\theta) = -\cos \theta + \sin \theta + C_1,$$

and all antiderivatives of $f'(\theta) = -\cos \theta + \sin \theta + C_1$ are

$$f(\theta) = -\sin \theta - \cos \theta + C_1\theta + C_2,$$

where C_1 and C_2 are constants. Applying the boundary condition that when $\theta = \frac{\pi}{2}$, then $f'(\frac{\pi}{2}) = 2$ yields

$$2 = -\cos \frac{\pi}{2} + \sin \frac{\pi}{2} + C_1 = 0 + 1 + C_1,$$

so that $C_1 = 1$. Next, applying the boundary condition that when $\theta = \pi$, then $f(\pi) = 4$ yields

$$4 = -\sin \pi - \cos \pi + \pi + C_2 = 0 - (-1) + \pi + C_2,$$

so that $C_2 = 3 - \pi$. The particular solution of the differential equation with the given boundary conditions is therefore

$$\boxed{f(\theta) = -\sin \theta - \cos \theta + \theta + 3 - \pi}.$$

41. The general solution of the differential equation $\frac{dv}{dt} = a(t) = -32$ is

$$v(t) = -32t + C_1,$$

where C_1 is a constant. Applying the initial condition $v(0) = 128$ yields

$$128 = -32(0) + C_1 = C_1,$$

so that $v(t) = -32t + 128$. Next, the general solution of the differential equation $\frac{ds}{dt} = v(t) = -32t + 128$ is

$$s(t) = -32 \cdot \frac{t^{1+1}}{1+1} + 128t + C_2 = -16t^2 + 128t + C_2.$$

Applying the initial condition $s(0) = 0$ yields

$$0 = -16(0)^2 + 128(0) + C_2 = C_2,$$

so that $\boxed{s(t) = -16t^2 + 128t}$.

42. The general solution of the differential equation $\frac{dv}{dt} = a(t) = -980$ is

$$v(t) = -980t + C_1,$$

where C_1 is a constant. Applying the initial condition $v(0) = 1980$ yields

$$1980 = -980(0) + C_1 = C_1,$$

so that $v(t) = -980t + 1980$. Next, the general solution of the differential equation $\frac{ds}{dt} = v(t) = -980t + 1980$ is

$$s(t) = -980 \cdot \frac{t^{1+1}}{1+1} + 1980t + C_2 = -490t^2 + 1980t + C_2.$$

Applying the initial condition $s(0) = 5$ yields

$$5 = -490(0)^2 + 1980(0) + C_2 = C_2,$$

so that $\boxed{s(t) = -490t^2 + 1980t + 5}$.

43. The general solution of the differential equation $\frac{dv}{dt} = a(t) = 3t$ is

$$v(t) = 3 \cdot \frac{t^{1+1}}{1+1} + C_1 = \frac{3}{2}t^2 + C_1,$$

where C_1 is a constant. Applying the initial condition $v(0) = 18$ yields

$$18 = \frac{3}{2}0^2 + C_1 = C_1,$$

so that $v(t) = \frac{3}{2}t^2 + 18$. Next, the general solution of the differential equation $\frac{ds}{dt} = v(t) = \frac{3}{2}t^2 + 18$ is

$$s(t) = \frac{3}{2} \cdot \frac{t^{2+1}}{2+1} + 18t + C_2 = \frac{1}{2}t^3 + 18t + C_2.$$

Applying the initial condition $s(0) = 2$ yields

$$2 = \frac{1}{2}(0)^3 + 18(0) + C_2 = C_2,$$

so that $s(t) = \frac{1}{2}t^3 + 18t + 2$.

44. The general solution of the differential equation $\frac{dv}{dt} = a(t) = 5t - 2$ is

$$v(t) = 5 \cdot \frac{t^{1+1}}{1+1} - 2t + C_1 = \frac{5}{2}t^2 - 2t + C_1,$$

where C_1 is a constant. Applying the initial condition $v(0) = 8$ yields

$$8 = \frac{5}{2}0^2 - 2(0) + C_1 = C_1,$$

so that $v(t) = \frac{5}{2}t^2 - 2t + 8$. Next, the general solution of the differential equation $\frac{ds}{dt} = v(t) = \frac{5}{2}t^2 - 2t + 8$ is

$$s(t) = \frac{5}{2} \cdot \frac{t^{2+1}}{2+1} - 2 \cdot \frac{t^{1+1}}{1+1} + 8t + C_2 = \frac{5}{6}t^3 - t^2 + 8t + C_2.$$

Applying the initial condition $s(0) = 0$ yields

$$0 = \frac{5}{6}(0)^3 - (0)^2 + 8(0) + C_2 = C_2,$$

so that $s(t) = \frac{5}{6}t^3 - t^2 + 8t$.

Applications and Extensions

45. Because $u^2 + 10u + 21 = (u + 3)(u + 7)$ and $3u + 9 = 3(u + 3)$,

$$f(u) = \frac{u^2 + 10u + 21}{3u + 9} = \frac{(u + 3)(u + 7)}{3(u + 3)} = \frac{u + 7}{3} = \frac{1}{3}u + \frac{7}{3},$$

for $u \neq -3$. Then, for $u \neq -3$, all of the antiderivatives of f are

$$F(u) = \frac{1}{3} \cdot \frac{u^2}{2} + \frac{7}{3}u + C = \boxed{\frac{1}{6}u^2 + \frac{7}{3}u + C},$$

where C is a constant.

46. Write

$$\frac{t^3 - 5t + 8}{t^5} \quad \text{as} \quad \frac{t^3}{t^5} - \frac{5t}{t^5} + \frac{8}{t^5} = t^{-2} - 5t^{-4} + 8t^{-5}.$$

Then, all of the antiderivatives of f are

$$F(t) = \frac{t^{-1}}{-1} - 5 \cdot \frac{t^{-3}}{-3} + 8 \cdot \frac{t^{-4}}{-4} + C = \boxed{-t^{-1} + \frac{5}{3}t^{-3} - 2t^{-4} + C},$$

where C is a constant.

47. Write

$$\frac{t^4 + 3t - 1}{t} \quad \text{as} \quad \frac{t^4}{t} + \frac{3t}{t} - \frac{1}{t} = t^3 + 3 - \frac{1}{t}.$$

The general solution of the differential equation

$$f'(t) = \frac{t^4 + 3t - 1}{t} = t^3 + 3 - \frac{1}{t}$$

is then

$$f(t) = \frac{1}{4}t^4 + 3t - \ln|t| + C,$$

where C is a constant. Applying the boundary condition that when $t = 1$, then $f(1) = \frac{1}{4}$ yields

$$\frac{1}{4} = \frac{1}{4}1^4 + 3(1) - \ln 1 + C = \frac{13}{4} + C,$$

so that $C = -3$. The particular solution of the differential equation with the given boundary condition is therefore

$$\boxed{f(t) = \frac{1}{4}t^4 + 3t - \ln|t| - 3}.$$

48. Write

$$\frac{x^2 - 1}{x^4 - 1} \quad \text{as} \quad \frac{x^2 - 1}{(x^2 - 1)(x^2 + 1)} = \frac{1}{x^2 + 1},$$

which is valid for $x \neq \pm 1$. The general solution of the differential equation

$$g'(x) = \frac{1}{x^2 + 1}$$

is $g(x) = \tan^{-1} x + C$, where C is a constant. Applying the boundary condition that when $x = 0$, then $g(0) = 0$ yields

$$0 = \tan^{-1} 0 + C = C,$$

so that $C = 0$. The particular solution of the differential equation with the given boundary condition is therefore

$$\boxed{g(x) = \tan^{-1} x},$$

provided $x \neq \pm 1$.

49. Given

$$\frac{d}{dx}(x \cos x + \sin x) = -x \sin x + 2 \cos x,$$

it follows that $x \cos x + \sin x$ is an antiderivative of the function $-x \sin x + 2 \cos x$. The general solution of the differential equation

$$\frac{dF}{dx} = -x \sin x + 2 \cos x$$

is $F(x) = x \cos x + \sin x + C$, where C is a constant. Applying the boundary condition that when $x = 0$, then $F(0) = 1$ yields

$$1 = 0 \cdot \cos 0 + \sin 0 + C = C.$$

The particular solution of the differential equation with the given boundary condition is therefore

$$\boxed{F(x) = x \cos x + \sin x + 1}.$$

50. Given

$$\frac{d}{dx} \sin x^2 = 2x \cos x^2,$$

it follows that

$$\frac{d}{dx} \left(\frac{1}{2} \sin x^2 \right) = x \cos x^2$$

and $\frac{1}{2} \sin x^2$ is an antiderivative of the function $x \cos x^2$. The general solution of the differential equation

$$\frac{dh}{dx} = x \cos x^2$$

is $h(x) = \frac{1}{2} \sin x^2 + C$, where C is a constant. Applying the boundary condition that when $x = 0$, then $h(0) = 2$ yields

$$2 = \frac{1}{2} \sin 0^2 + C = C.$$

The particular solution of the differential equation with the given boundary condition is therefore

$$\boxed{h(x) = \frac{1}{2} \sin x^2 + 2}.$$

51. Let $t = 0$ denote the time the brakes are applied, let v_0 denote the speed of the car when the brakes are applied, and let $s(t)$ represent the distance the car has traveled t seconds after the brakes have been applied. Because the car decelerates at the rate of 10 m/s^2 , its acceleration a is given by

$$a(t) = \frac{dv}{dt} = -10.$$

Solve this differential equation for $v(t)$ to obtain $v(t) = -10t + C_1$, where C_1 is a constant. Applying the initial condition $v(0) = v_0$ yields

$$v_0 = -10(0) + C_1 = C_1,$$

so that $C_1 = v_0$ and $v(t) = -10t + v_0$. Next, solve the differential equation

$$\frac{ds}{dt} = v(t) = -10t + v_0$$

to obtain

$$s(t) = -10 \cdot \frac{t^2}{2} + v_0 t + C_2 = -5t^2 + v_0 t + C_2,$$

where C_2 is a constant. Applying the initial condition $s(0) = 0$ gives

$$0 = -5(0)^2 + v_0(0) + C_2 = C_2,$$

so that $C_2 = 0$ and $s(t) = -5t^2 + v_0 t$. Now, the car comes to a stop when its speed is equal to zero; that is when

$$-10t + v_0 = 0 \quad \text{or} \quad t = \frac{v_0}{10}.$$

By the time the car comes to rest, it has traveled

$$s\left(\frac{v_0}{10}\right) = -5\left(\frac{v_0}{10}\right)^2 + v_0 \cdot \frac{v_0}{10} = \frac{v_0^2}{20} \text{ meters}$$

from the moment the brakes were applied. If the car is to stop within 15 meters, then

$$s\left(\frac{v_0}{10}\right) \leq 15 \quad \text{or} \quad \frac{v_0^2}{20} \leq 15.$$

The maximum possible velocity for the car is therefore $\boxed{v_0 = 10\sqrt{3} \text{ m/s} \approx 17.32 \text{ m/s}}$. In miles per hour, this is approximately

$$10\sqrt{3} \text{ m/s} \cdot \frac{3600 \text{ s}}{1 \text{ h}} \cdot \frac{1 \text{ km}}{1000 \text{ m}} \cdot \frac{1 \text{ mi}}{1.60934 \text{ km}} \approx \boxed{38.74 \text{ mi/h}}.$$

52. Let $t = 0$ denote the time that the car begins to accelerate, and let $s(t)$ represent the distance the car has traveled after t seconds. Because the car accelerates at a constant rate from 0 to 60 km/h in 10 s, its acceleration a is given by

$$a = \frac{60 \text{ km/h}}{10 \text{ s}} \cdot \frac{1000 \text{ m}}{1 \text{ km}} \cdot \frac{1 \text{ h}}{3600 \text{ s}} = \frac{5}{3} \text{ m/s}^2.$$

Solve the differential equation

$$\frac{dv}{dt} = a(t) = \frac{5}{3}$$

for $v(t)$ to obtain $v(t) = \frac{5}{3}t + C_1$, where C_1 is a constant. Apply the initial condition $v(0) = 0$ to determine

$$0 = \frac{5}{3}(0) + C_1 = C_1,$$

so that $v(t) = \frac{5}{3}t$. Next, solve the differential equation

$$\frac{ds}{dt} = v(t) = \frac{5}{3}t$$

for $s(t)$ to obtain

$$s(t) = \frac{5}{3} \cdot \frac{t^2}{2} + C_2 = \frac{5}{6}t^2 + C_2.$$

The initial condition $s(0) = 0$ determines

$$0 = \frac{5}{6}(0)^2 + C_2 = C_2,$$

so $s(t) = \frac{5}{6}t^2$. Therefore, after 10 seconds, the car has traveled

$$s(10) = \frac{5}{6}(10)^2 = \boxed{\frac{250}{3} \text{ m}}.$$

53. Let $t = 0$ denote the time that the car begins to accelerate, and let $s(t)$ represent the distance the car has traveled after t seconds. Because the car accelerates at a constant rate from 0 to 60 mph in 5 s, its acceleration a is given by

$$a = \frac{60 \text{ mph}}{5 \text{ s}} \cdot \frac{5280 \text{ ft}}{1 \text{ mi}} \cdot \frac{1 \text{ h}}{3600 \text{ s}} = 17.6 \text{ ft/s}^2.$$

Solve the differential equation

$$\frac{dv}{dt} = a(t) = 17.6$$

for $v(t)$ to obtain $v(t) = 17.6t + C_1$, where C_1 is a constant. Apply the initial condition $v(0) = 0$ to determine

$$0 = 17.6(0) + C_1 = C_1,$$

so that $v(t) = 17.6t$. Next, solve the differential equation

$$\frac{ds}{dt} = v(t) = 17.6t$$

for $s(t)$ to obtain

$$s(t) = 17.6 \cdot \frac{t^2}{2} + C_2 = 8.8t^2 + C_2.$$

The initial condition $s(0) = 0$ determines

$$0 = 8.8(0)^2 + C_2 = C_2,$$

so $s(t) = 8.8t^2$. Therefore, after 5 seconds, the car has traveled

$$s(5) = 8.8(5)^2 = \boxed{220 \text{ ft}}.$$

54. First consider the athlete jumping on Earth. Let $t = 0$ denote the time the athlete loses contact with the ground, let v_0 denote the initial upward speed of the athlete, and let $s(t)$ represent the height of the athlete t seconds after initiating the jump. The general solution of the differential equation

$$\frac{dv}{dt} = a(t) = -9.8$$

is $v(t) = -9.8t + C_1$, where C_1 is a constant. Applying the initial condition $v(0) = v_0$ yields

$$v_0 = -9.8(0) + C_1 = C_1,$$

so that $C_1 = v_0$ and $v(t) = -9.8t + v_0$. Next, solve the differential equation

$$\frac{ds}{dt} = v(t) = -9.8t + v_0$$

to obtain

$$s(t) = -9.8 \cdot \frac{t^2}{2} + v_0t + C_2 = -4.9t^2 + v_0t + C_2,$$

where C_2 is a constant. Applying the initial condition $s(0) = 0$ gives

$$0 = -4.9(0)^2 + v_0(0) + C_2 = C_2,$$

so that $C_2 = 0$ and $s(t) = -4.9t^2 + v_0t$. Now, the athlete achieves his/her maximum height when $v(t)$ is equal to zero; that is when

$$-9.8t + v_0 = 0 \quad \text{or} \quad t = \frac{v_0}{9.8}.$$

Substituting this time into $s(t)$ and setting the resulting expression equal to 2 gives

$$2 = -\frac{v_0^2}{19.6} + \frac{v_0^2}{9.8} = \frac{v_0^2}{19.6},$$

so that

$$v_0 = \sqrt{39.2} \text{ m/s}.$$

Now, consider the athlete jumping on the moon. Assume the condition that “the athlete can propel himself or herself with the same force on the moon as on Earth” means that the athlete produces the same initial velocity, $v_0 = \sqrt{39.2}$ m/s, as on Earth. Following the procedure used above, with an acceleration due to gravity on the moon of 1.6 m/s^2 , the athlete’s velocity during the jump on the moon is

$$v(t) = -1.6t + \sqrt{39.2},$$

so the athlete achieves maximum height when

$$-1.6t + \sqrt{39.2} = 0 \quad \text{or} \quad t = \frac{\sqrt{39.2}}{1.6} = \sqrt{15.3125} \text{ s.}$$

The height of the athlete t seconds after initiating the jump is

$$s(t) = -1.6 \frac{t^2}{2} + \sqrt{39.2}t = -0.8t^2 + \sqrt{39.2}t,$$

so

$$\begin{aligned} s(\sqrt{15.3125}) &= -0.8(15.3125) + \sqrt{39.2} \cdot \sqrt{15.3125} \\ &= -12.25 + \sqrt{600.25} = 12.25 \text{ m.} \end{aligned}$$

On the moon, the athlete would attain a height of 12.25 m.

55. First consider Javier Sotomayor jumping on Earth. Let $t = 0$ denote the time Sotomayor loses contact with the ground, let v_0 denote his initial upward speed, and let $s(t)$ represent his height t seconds after initiating the jump. The general solution of the differential equation

$$\frac{dv}{dt} = a(t) = -9.8$$

is $v(t) = -9.8t + C_1$, where C_1 is a constant. Applying the initial condition $v(0) = v_0$ yields

$$v_0 = -9.8(0) + C_1 = C_1,$$

so that $C_1 = v_0$ and $v(t) = -9.8t + v_0$. Next, solve the differential equation

$$\frac{ds}{dt} = v(t) = -9.8t + v_0$$

to obtain

$$s(t) = -9.8 \cdot \frac{t^2}{2} + v_0t + C_2 = -4.9t^2 + v_0t + C_2,$$

where C_2 is a constant. Applying the initial condition $s(0) = 0$ gives

$$0 = -4.9(0)^2 + v_0(0) + C_2 = C_2,$$

so that $C_2 = 0$ and $s(t) = -4.9t^2 + v_0t$. Now, Sotomayor achieves his maximum height when $v(t)$ is equal to zero; that is when

$$-9.8t + v_0 = 0 \quad \text{or} \quad t = \frac{v_0}{9.8}.$$

Substituting this time into $s(t)$ and setting the resulting expression equal to 2.45 gives

$$2.45 = -\frac{v_0^2}{19.6} + \frac{v_0^2}{9.8} = \frac{v_0^2}{19.6},$$

so that

$$v_0 = \sqrt{48.02} \text{ m/s.}$$

Now, consider Javier Sotomayor jumping on the moon. Assume the condition that “he propels himself with the same force on the moon as on Earth” means that Sotomayor produces the same initial velocity,

$v_0 = \sqrt{48.02}$ m/s, as on Earth. Following the procedure used above, with an acceleration due to gravity on the moon of 1.6 m/s^2 , Sotomayor's velocity during the jump on the moon is

$$v(t) = -1.6t + \sqrt{48.02},$$

so that he achieves maximum height when

$$-1.6t + \sqrt{48.02} = 0 \quad \text{or} \quad t = \frac{\sqrt{48.02}}{1.6} \text{ s.}$$

Sotomayor's height t seconds after initiating the jump is

$$s(t) = -1.6 \frac{t^2}{2} + \sqrt{48.02}t = -0.8t^2 + \sqrt{48.02}t,$$

so

$$s\left(\frac{\sqrt{48.02}}{1.6}\right) = -\frac{48.02}{3.2} + \frac{48.02}{1.6} = \frac{48.02}{3.2} = \boxed{15.00625 \text{ m}}.$$

On the moon, Sotomayor would attain a height of a little more than 15 m.

56. Let $t = 0$ denote the time at which the ball is released, and let $v(t)$ and $s(t)$ represent the upward speed of the ball and the height of the ball above ground level, respectively, t seconds after release. Given that the initial upward speed of the ball is 19.6 m/s and the ball is released from ground level, it follows that $v(0) = 19.6$ and $s(0) = 0$. Now, solve the differential equation

$$\frac{dv}{dt} = a(t) = -9.8$$

to obtain $v(t) = -9.8t + C_1$, where C_1 is a constant. The initial condition $v(0) = 19.6$ determines

$$19.6 = -9.8(0) + C_1 = C_1,$$

so $v(t) = -9.8t + 19.6$. Next, solve the differential equation

$$\frac{ds}{dt} = v(t) = -9.8t + 19.6$$

for $s(t)$ to obtain

$$s(t) = -9.8 \frac{t^2}{2} + 19.6t + C_2 = -4.9t^2 + 19.6t + C_2.$$

Use the initial condition $s(0) = 0$ to determine

$$0 = -4.9(0)^2 + 19.6(0) + C_2 = C_2,$$

so $s(t) = -4.9t^2 + 19.6t$. The ball reaches its maximum height when $v(t) = 0$; that is, when

$$-9.8t + 19.6 = 0 \quad \text{or} \quad t = 2 \text{ s.}$$

The maximum height is therefore

$$s(2) = -4.9(2)^2 + 19.6(2) = \boxed{19.6 \text{ m}}.$$

The ball is at ground level when $s(t) = 0$; that is, when

$$-4.9t^2 + 19.6t = -4.9t(t - 4) = 0 \quad \text{or} \quad t = 0, 4 \text{ s.}$$

Because $t = 0$ is the time the ball was released, $t = 4$ is the time the ball returns to the ground. The ball returns to ground level after $\boxed{4 \text{ seconds}}$.

57. Let v_0 denote the initial upward velocity of the ball, let $t = 0$ denote the time at which the ball is released, and let $v(t)$ and $s(t)$ represent the upward speed of the ball and the height of the ball above ground level, respectively, t seconds after release. Given that the ball is released at an initial height of 1 m, it follows that $s(0) = 1$. Now, solve the differential equation

$$\frac{dv}{dt} = a(t) = -9.8$$

to obtain $v(t) = -9.8t + C_1$, where C_1 is a constant. The initial condition $v(0) = v_0$ determines

$$v_0 = -9.8(0) + C_1 = C_1,$$

so $v(t) = -9.8t + v_0$. Next, solve the differential equation

$$\frac{ds}{dt} = v(t) = -9.8t + v_0$$

for $s(t)$ to obtain

$$s(t) = -9.8\frac{t^2}{2} + v_0t + C_2 = -4.9t^2 + v_0t + C_2.$$

Use the initial condition $s(0) = 1$ to determine

$$1 = -4.9(0)^2 + v_0(0) + C_2 = C_2,$$

so $s(t) = -4.9t^2 + v_0t + 1$. The ball reaches its maximum height when $v(t) = 0$; that is, when

$$-9.8t + v_0 = 0 \quad \text{or} \quad t = \frac{v_0}{9.8} \text{ s.}$$

The maximum height is therefore

$$s\left(\frac{v_0}{9.8}\right) = -4.9\left(\frac{v_0}{9.8}\right)^2 + v_0\left(\frac{v_0}{9.8}\right) + 1 = \frac{v_0^2}{19.6} + 1 \text{ m.}$$

To achieve a maximum height of at least 9.8 m requires

$$\frac{v_0^2}{19.6} + 1 \geq 9.8 \quad \text{or} \quad v_0 \geq \sqrt{19.6(8.8)} \approx \boxed{13.133 \text{ m/s}}.$$

58. Let v_0 denote the initial velocity of the ball, let $t = 0$ denote the time at which the ball is released, and let $v(t)$ and $s(t)$ represent the upward speed of the ball and the height of the ball above ground level, respectively, t seconds after release. Given that the ball is released at an initial height of 49 m, it follows that $s(0) = 49$. Now, solve the differential equation

$$\frac{dv}{dt} = a(t) = -9.8$$

to obtain $v(t) = -9.8t + C_1$, where C_1 is a constant. The initial condition $v(0) = v_0$ determines

$$v_0 = -9.8(0) + C_1 = C_1,$$

so $v(t) = -9.8t + v_0$. Next, solve the differential equation

$$\frac{ds}{dt} = v(t) = -9.8t + v_0$$

for $s(t)$ to obtain

$$s(t) = -9.8\frac{t^2}{2} + v_0t + C_2 = -4.9t^2 + v_0t + C_2.$$

Use the initial condition $s(0) = 49$ to determine

$$49 = -4.9(0)^2 + v_0(0) + C_2 = C_2,$$

so $s(t) = -4.9t^2 + v_0t + 49$. Because the ball reaches the ground after 3 seconds, $s(3) = 0$. Therefore,

$$0 = -4.9(3)^2 + v_0(3) + 49 \quad \text{so} \quad v_0 = \frac{44.1 - 49}{3} \approx -1.633 \text{ m/s}.$$

In other words, the ball is released with a downward speed of approximately 1.633 m/s.

59. Note that constant force implies constant acceleration. Given that the object is initially at rest and has a velocity of 12 m/s after 6 s, the acceleration a of the object is

$$a = \frac{12 - 0}{6} = 2 \text{ m/s}^2.$$

By Newton's Second Law, $F = ma$, so the force applied to the object is

$$F = ma = 4(2) = \boxed{8 \text{ N}}.$$

60. Let a denote the constant acceleration of the car, let $t = 0$ denote the time at which the car begins accelerating, and let $v(t)$ and $s(t)$ represent the velocity of the car and the distance traveled by the car, respectively, t minutes after it begins accelerating. Given that the car is initially at rest, it follows that $v(0) = 0$. Additionally, by the definition of $s(t)$, $s(0) = 0$. Now, solve the differential equation

$$\frac{dv}{dt} = a$$

to obtain $v(t) = at + C_1$, where C_1 is a constant. The initial condition $v(0) = 0$ determines

$$0 = a(0) + C_1 = C_1,$$

so $v(t) = at$. Next, solve the differential equation

$$\frac{ds}{dt} = v(t) = at$$

for $s(t)$ to obtain

$$s(t) = a\frac{t^2}{2} + C_2 = \frac{1}{2}at^2 + C_2.$$

Use the initial condition $s(0) = 0$ to determine

$$0 = \frac{1}{2}a(0)^2 + C_2 = C_2,$$

so $s(t) = \frac{1}{2}at^2$. Because the car travels 2 km in 2 min, $s(2) = 2$. Therefore

$$2 = \frac{1}{2}a(2)^2 \quad \text{or} \quad a = 1 \text{ km/min}^2.$$

In centimeters per second squared, this is

$$a = 1 \frac{\text{km}}{\text{min}^2} \cdot \frac{100000 \text{ cm}}{1 \text{ km}} \left(\frac{1 \text{ min}}{60 \text{ s}} \right)^2 = \boxed{\frac{250}{9} \text{ cm/s}^2}.$$

61. Let $a = g \sin 20^\circ = 9.8 \sin 20^\circ$. The general solution of the differential equation

$$\frac{dv}{dt} = a = 9.8 \sin 20^\circ$$

is

$$v(t) = (9.8 \sin 20^\circ)t + C,$$

where C is a constant. The initial condition $v(0) = 0$ (the skier starts from rest) determines

$$0 = 9.8 \sin 20^\circ(0) + C = C,$$

so

$$v(t) = (9.8 \sin 20^\circ)t.$$

After 5 seconds,

$$v(5) = 9.8 \sin 20^\circ(5) \approx \boxed{16.759 \text{ m/s}}.$$

62. Start with the first rock. Let $t = 0$ denote the time when this rock is released. Because this rock is released from rest at a height of 24 m, $v(0) = 0$ and $s(0) = 24$. The general solution of the differential equation

$$\frac{dv}{dt} = a = -9.8$$

is $v(t) = -9.8t + C_1$, where C_1 is a constant. The initial condition $v(0) = 0$ determines

$$0 = -9.8(0) + C_1 = C_1,$$

so $v(t) = -9.8t$. Solving the differential equation

$$\frac{ds}{dt} = v(t) = -9.8t$$

yields $s(t) = -4.9t^2 + C_2$. The initial condition $s(0) = 24$ determines

$$24 = -4.9(0)^2 + C_2 = C_2,$$

so $s(t) = -4.9t^2 + 24$, and the first rock reaches the ground when

$$-4.9t^2 + 24 = 0 \quad \text{or} \quad t = \sqrt{\frac{24}{4.9}} \text{ s.}$$

Now, the second rock was released at $t = 1$ with $s(1) = 24$ and $v(1) = v_0$. The general solution of the differential equation

$$\frac{dv}{dt} = a = -9.8$$

is $v(t) = -9.8t + C_3$, where C_3 is a constant. The initial condition $v(1) = v_0$ determines

$$v_0 = -9.8(1) + C_3 = C_3 - 9.8,$$

so $v(t) = -9.8t + v_0 + 9.8$. Solving the differential equation

$$\frac{ds}{dt} = v(t) = -9.8t + v_0 + 9.8$$

yields $s(t) = -4.9t^2 + (v_0 + 9.8)t + C_4$. The initial condition $s(1) = 24$ determines

$$24 = -4.9(1)^2 + (v_0 + 9.8)(1) + C_4 = C_4 + v_0 + 4.9,$$

so $s(t) = -4.9t^2 + (v_0 + 9.8)t + 19.1 - v_0$. Now,

$$s\left(\sqrt{\frac{24}{4.9}}\right) = -4.9\left(\sqrt{\frac{24}{4.9}}\right)^2 + (v_0 + 9.8)\sqrt{\frac{24}{4.9}} + 19.1 - v_0 = 0,$$

so

$$v_0 = \frac{24 - 9.8\sqrt{\frac{24}{4.9}} - 19.1}{\sqrt{\frac{24}{4.9}} - 1} \approx -13.839.$$

The second rock was thrown downward with an initial velocity of approximately 13.839 m/s.

Challenge Problems

63. (a) Let $I(x)$ denote the intensity of the radiation at the depth x into the tissue. The rate of change of the intensity of the radiation with respect to the depth x is then $\frac{dI}{dx}$. Given that intensity of the radiation decreases with increasing depth (because radiation is absorbed as it passes through the tissue) and that the rate of change is proportional to the intensity with positive constant of proportionality k , it follows that

$$\frac{dI}{dx} = -kI.$$

- (b) Because the constant of proportionality k has been designated to be positive, the negative sign is needed in the differential equation in part (a) to ensure that the intensity of the radiation decreases with increasing depth.
- (c) To solve the differential equation from part (a), we need to find the most general function whose derivative is $-k$ times itself. Note that e^{-kx} is one such function whose derivative is $-k$ times itself; that is

$$\frac{d}{dx}e^{-kx} = e^{-kx} \cdot (-k) = -ke^{-kx}.$$

Now, suppose that f is *any* function for which $f'(x) = -kf(x)$ and consider the function $f(x)e^{kx}$. Because

$$\frac{d}{dx}[f(x)e^{kx}] = f(x) \cdot ke^{kx} + e^{kx} \cdot f'(x) = kf(x)e^{kx} - kf(x)e^{kx} = 0,$$

it follows that $f(x)e^{kx}$ is equal to some constant C . In other words, if f is a function for which $f'(x) = -kf(x)$, then $f(x) = Ce^{-kx}$ for some constant C . It follows that

$$I(x) = Ce^{-kx}$$

for some constant C . Applying the initial condition $I(0) = I_0$ yields

$$I_0 = Ce^{-k(0)} = C;$$

therefore, $I(x) = I_0e^{-kx}$.

- (d) If the intensity is reduced by 90% at the depth of 2.0 cm, then $I(2.0) = 0.1I_0$. Using the formula for $I(x)$ from part (c),

$$0.1I_0 = I_0e^{-2k} \quad \text{so that} \quad k = \left[-\frac{1}{2} \ln 0.1 \text{ cm}^{-1} \right].$$

64. Let $t = 0$ denote the time at which the ball is released, and let $v(t)$ and $s(t)$ represent the upward speed of the ball and the height of the ball above ground level, respectively, t seconds after release.

Given that the initial upward speed of the ball is 19.6 m/s and the ball is released from an initial height of 1 m above ground, it follows that $v(0) = 19.6$ and $s(0) = 1$. Now, solve the differential equation

$$\frac{dv}{dt} = a(t) = -9.8$$

to obtain $v(t) = -9.8t + C_1$, where C_1 is a constant. The initial condition $v(0) = 19.6$ determines

$$19.6 = -9.8(0) + C_1 = C_1,$$

so $v(t) = -9.8t + 19.6$. Next, solve the differential equation

$$\frac{ds}{dt} = v(t) = -9.8t + 19.6$$

for $s(t)$ to obtain

$$s(t) = -9.8 \frac{t^2}{2} + 19.6t + C_2 = -4.9t^2 + 19.6t + C_2.$$

Use the initial condition $s(0) = 1$ to determine

$$1 = -4.9(0)^2 + 19.6(0) + C_2 = C_2,$$

so $s(t) = -4.9t^2 + 19.6t + 1$.

Now, 3 seconds after the ball is released,

$$v(3) = -9.8(3) + 19.6 = -9.8 \text{ m/s} \quad \text{and} \quad s(3) = -4.9(3)^2 + 19.6(3) + 1 = 15.7 \text{ m}.$$

Let $y(t)$ denote the height of the shadow of the ball on the wall at time t . By similar triangles (see the diagram below),

$$\frac{5}{25} = \frac{s-10}{y-10} \quad \text{so that} \quad y-10 = 5(s-10) \quad \text{or} \quad y = 5s - 40.$$

Therefore,

$$\frac{dy}{dt} = 5 \frac{ds}{dt} \quad \text{so} \quad \left. \frac{dy}{dt} \right|_{t=3} = 5 \left. \frac{ds}{dt} \right|_{t=3} = 5v(3) = -49 \text{ m/s}.$$

Finally, 3 seconds after the ball is released,

- (a) the shadow of the ball is moving down the wall at a rate of 49 m/s;
- (b) the ball has a velocity of -9.8 m/s, so it is moving down; and
- (c) the ball is 15.7 m above the ground.

Chapter 4 Review Exercises

1. The volume and surface area of a sphere of radius r are

$$V = \frac{4}{3}\pi r^3 \quad \text{and} \quad S = 4\pi r^2,$$

respectively. Differentiating with respect to time,

$$\frac{dV}{dt} = 4\pi r^2 \frac{dr}{dt} \quad \text{and} \quad \frac{dS}{dt} = 8\pi r \frac{dr}{dt}.$$

Solving the first equation for $\frac{dr}{dt}$ and substituting into the second equation yields

$$\frac{dS}{dt} = \frac{8\pi r}{4\pi r^2} \frac{dV}{dt} = \frac{2}{r} \frac{dV}{dt}.$$

Given that the snowball is melting at the rate of $2 \text{ cm}^3/\text{min}$,

$$\frac{dV}{dt} = -2.$$

When $r = 5 \text{ cm}$,

$$\frac{dS}{dt} = \frac{2}{5}(-2) = \boxed{-\frac{4}{5} \text{ cm}^2/\text{min}}.$$

2. Let x denote the distance between the point on the shoreline nearest to the lighthouse and the point on the shoreline on which the light beam is shining, and let θ denote the angle between the light beam and the perpendicular to the shoreline (see the diagram below). Then

$$\tan \theta = \frac{x}{3} \quad \text{so that} \quad x = 3 \tan \theta.$$

Differentiating with respect to time yields

$$\frac{dx}{dt} = 3 \sec^2 \theta \frac{d\theta}{dt}.$$

Given that the light makes one revolution every 8 seconds,

$$\frac{d\theta}{dt} = \frac{2\pi \text{ rad}}{8 \text{ s}} = \frac{\pi}{4} \text{ rad/s}.$$

When the light makes an angle of 30° with the shoreline, $\theta = 60^\circ$, and

$$\frac{dx}{dt} = 3 \sec^2 60^\circ \cdot \frac{\pi}{4} = 3(4) \frac{\pi}{4} = \boxed{3\pi \text{ km/s}}.$$

3. Let $x(t)$ denote the distance between the plane approaching the airport from the west and the airport, and let $y(t)$ denote the distance between the plane approaching the airport from the north and the airport. The distance D between the two planes is then

$$D = \sqrt{x^2 + y^2}.$$

Differentiating with respect to time yields

$$\frac{dD}{dt} = \frac{x \cdot \frac{dx}{dt} + y \cdot \frac{dy}{dt}}{\sqrt{x^2 + y^2}}.$$

Given that the plane to the west is approaching the airport at 200 mph and the plane to the north is approaching the airport at 250 mph,

$$\frac{dx}{dt} = -200 \quad \text{and} \quad \frac{dy}{dt} = -250.$$

When $x = 20$ miles and $y = 30$ miles,

$$\frac{dD}{dt} = \frac{20 \cdot -200 + 30 \cdot -250}{\sqrt{20^2 + 30^2}} = \frac{-11500}{\sqrt{1300}} \approx -318.953 \text{ mph}.$$

The two planes are approaching one another at approximately 318.953 mph.

4. For the function given in the graph,

$(-10, 0)$:	neither
$(-8, -4)$:	local minimum and absolute minimum
$(-5, 0)$:	neither
$(-2, 6)$:	local maximum
$(0, 0)$:	local minimum
$(2, 10)$:	local maximum and absolute maximum
$(5, 0)$:	neither

5. For the function given in the graph,

$(-8, -9)$:	absolute minimum
$(-5, 0)$:	neither
$(-2, 9)$:	local maximum and absolute maximum
$(1, 0)$:	local minimum
$(3, 4)$:	local maximum
$(5, 0)$:	neither

6. Let $f(x) = \frac{x^2}{2x-1}$.

- (a) The domain of f is the set $\left\{x \mid x \neq \frac{1}{2}\right\}$, and

$$f'(x) = \frac{(2x-1) \cdot 2x - x^2 \cdot 2}{(2x-1)^2} = \frac{4x^2 - 2x - 2x^2}{(2x-1)^2} = \frac{2x(x-1)}{(2x-1)^2}.$$

The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now, $f'(x)$ is equal to zero when $x = 0$ and when $x = 1$ and does not exist when $x = \frac{1}{2}$. Because $\frac{1}{2}$ is not in the domain of f , $\frac{1}{2}$ is not a critical number, so 0 and 1 are the only critical numbers.

- (b) To apply the Increasing/Decreasing Function Test, use the numbers 0, $\frac{1}{2}$, and 1 to divide the number line into four intervals.

Interval	Sign of f'	Conclusion
$(-\infty, 0)$	+	f is increasing on $(-\infty, 0)$
$(0, \frac{1}{2})$	-	f is decreasing on $(0, \frac{1}{2})$
$(\frac{1}{2}, 1)$	-	f is decreasing on $(\frac{1}{2}, 1)$
$(1, \infty)$	+	f is increasing on $(1, \infty)$

By the First Derivative Test and the information in the table above, f has a local maximum value at 0 and a local minimum value at 1. The local maximum value is $f(0) = 0$, while the local minimum value is $f(1) = 1$.

7. Let $f(x) = \cos(2x)$ and consider the closed interval $[0, \pi]$. Because the trigonometric function f is differentiable everywhere, the critical numbers of f occur where $f'(x) = 0$. Now,

$$f'(x) = -2\sin(2x),$$

so $f'(x) = 0$ when $2x = n\pi$ for any integer n . It follows that $x = \frac{n\pi}{2}$ is a critical number for any integer n . Among these numbers, only 0, $\frac{\pi}{2}$, and π lie on the closed interval $[0, \pi]$. Therefore, 0, $\frac{\pi}{2}$, and π are the critical numbers of f on the closed interval $[0, \pi]$.

8. Let $f(x) = x - \sin(2x)$, and consider the closed interval $[0, 2\pi]$. Because f is continuous on this closed interval, the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute minimum on $[0, 2\pi]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the open interval. Now, f is differentiable everywhere, which means that the critical numbers of f occur where $f'(x) = 0$. Moreover,

$$f'(x) = 1 - 2\cos(2x) = 0$$

when $\cos(2x) = \frac{1}{2}$. On the interval $0 \leq x \leq 2\pi$, $\cos(2x) = \frac{1}{2}$ when $x = \frac{\pi}{6}$, $x = \frac{5\pi}{6}$, $x = \frac{7\pi}{6}$, and $x = \frac{11\pi}{6}$. Evaluating f at the endpoints of the interval $[0, 2\pi]$ and the four critical numbers yields

$$\begin{aligned} f(0) &= 0 - \sin 0 = 0 \\ f\left(\frac{\pi}{6}\right) &= \frac{\pi}{6} - \sin \frac{\pi}{3} = \frac{\pi}{6} - \frac{\sqrt{3}}{2} \approx -0.342 \\ f\left(\frac{5\pi}{6}\right) &= \frac{5\pi}{6} - \sin \frac{5\pi}{3} = \frac{5\pi}{6} + \frac{\sqrt{3}}{2} \approx 3.484 \\ f\left(\frac{7\pi}{6}\right) &= \frac{7\pi}{6} - \sin \frac{7\pi}{3} = \frac{7\pi}{6} - \frac{\sqrt{3}}{2} \approx 2.799 \\ f\left(\frac{11\pi}{6}\right) &= \frac{11\pi}{6} - \sin \frac{11\pi}{3} = \frac{11\pi}{6} + \frac{\sqrt{3}}{2} \approx 6.626 \\ f(2\pi) &= 2\pi - \sin(4\pi) = 2\pi \approx 6.283. \end{aligned}$$

Therefore, the absolute maximum value of f on the interval $[0, 2\pi]$ is $\frac{11\pi}{6} + \frac{\sqrt{3}}{2}$ (and this occurs at the critical number $x = \frac{11\pi}{6}$), while the absolute minimum value of f is $\frac{\pi}{6} - \frac{\sqrt{3}}{2}$ (and this occurs at the critical number $x = \frac{\pi}{6}$).

9. Let $f(x) = \frac{3}{2}x^4 - 2x^3 - 6x^2 + 5$, and consider the closed interval $[-2, 3]$. Because f is continuous on this closed interval, the Extreme Value Theorem guarantees that f has an absolute maximum and an absolute minimum on $[-2, 3]$. The absolute maximum and absolute minimum can only occur at the endpoints of the interval or at the critical numbers inside the interval. Now, the polynomial function f is differentiable everywhere, which means that the critical numbers of f occur where $f'(x) = 0$. Moreover,

$$f'(x) = 6x^3 - 6x^2 - 12x = 6x(x^2 - x - 2) = 6x(x - 2)(x + 1) = 0$$

when $x = -1$, $x = 0$, and $x = 2$. Evaluating f at the endpoints of the interval $[-2, 3]$ and at the three critical numbers yields

$$f(-2) = 21, \quad f(-1) = \frac{5}{2}, \quad f(0) = 5, \quad f(2) = -11, \quad f(3) = \frac{37}{2}.$$

Therefore, the absolute maximum value of f on the interval $[-2, 3]$ is $\boxed{21}$ (and this occurs at the endpoint $x = -2$), while the absolute minimum value of f is $\boxed{-11}$ (and this occurs at the critical number $x = 2$).

10. Let $f(x) = x^3 - 4x^2 + 4x$. The polynomial function f is continuous and differentiable everywhere, so it is continuous on the closed interval $[0, 2]$ and differentiable on the open interval $(0, 2)$. Additionally,

$$f(0) = 0 \quad \text{and} \quad f(2) = 2^3 - 4(2)^2 + 4(2) = 0,$$

so $f(0) = f(2)$. The function f therefore satisfies all three conditions of Rolle's Theorem on the interval $[0, 2]$. Now, $f'(x) = 3x^2 - 8x + 4 = (3x - 2)(x - 2)$, so $f'(c) = 0$ when $c = \frac{2}{3}$ and when $c = 2$. Both of these values are in the interval $[0, 2]$. There is a horizontal tangent line to the graph of f at the points

$$\boxed{\left(\frac{2}{3}, \frac{32}{27}\right) \text{ and } (2, 0)}.$$

11. Let $f(x) = \frac{2x-1}{x} = 2 - \frac{1}{x}$. The function f is continuous and differentiable on the set $\{x|x \neq 0\}$, so it is continuous on the closed interval $[1, 4]$ and differentiable on the open interval $(1, 4)$. The function f therefore satisfies the conditions of the Mean Value Theorem on the interval $[1, 4]$. Now,

$$f'(x) = \frac{1}{x^2} \quad \text{and} \quad \frac{f(b) - f(a)}{b - a} = \frac{f(4) - f(1)}{4 - 1} = \frac{\frac{7}{4} - 1}{3} = \frac{1}{4},$$

so

$$f'(c) = \frac{f(b) - f(a)}{b - a} \quad \text{when} \quad \frac{1}{c^2} = \frac{1}{4}.$$

Therefore, $c = \pm 2$. Of these numbers, only $c = 2$ is in the interval $(1, 4)$. Finally, at the point $\boxed{\left(2, \frac{3}{2}\right)}$,

the graph of f has a tangent line with a slope equal to that of the secant line joining $(1, 1)$ and $\left(4, \frac{7}{4}\right)$.

12. Let $f(x) = \sqrt{x}$. The function f is continuous on the set $\{x|x \geq 0\}$ and differentiable on the set $\{x|x > 0\}$, so it is continuous on the closed interval $[0, 9]$ and differentiable on the open interval $(0, 9)$. The function f therefore satisfies the conditions of the Mean Value Theorem on the interval $[0, 9]$. Now,

$$f'(x) = \frac{1}{2\sqrt{x}} \quad \text{and} \quad \frac{f(b) - f(a)}{b - a} = \frac{f(9) - f(0)}{9 - 0} = \frac{3 - 0}{9} = \frac{1}{3},$$

so

$$f'(c) = \frac{f(b) - f(a)}{b - a} \quad \text{when} \quad \frac{1}{2\sqrt{c}} = \frac{1}{3}.$$

Therefore, $\boxed{c = \left(\frac{3}{2}\right)^2 = \frac{9}{4}}$.

13. Let $f(x) = x^3 - x^2 - 8x + 1$. The polynomial function f is differentiable everywhere, so critical numbers occur where $f'(x) = 0$. Now,

$$f'(x) = 3x^2 - 2x - 8 = (3x + 4)(x - 2),$$

so 2 and $-\frac{4}{3}$ are the critical numbers of f .

- (a) To determine where $f'(x) > 0$ and $f'(x) < 0$, use the numbers 2 and $-\frac{4}{3}$ to divide the number line into three intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $3x + 4$	Sign of $x - 2$	Sign of $f'(x)$	Conclusion
$(-\infty, -\frac{4}{3})$	—	—	+	f is increasing
$(-\frac{4}{3}, 2)$	+	—	—	f is decreasing
$(2, \infty)$	+	+	+	f is increasing

Therefore, f is increasing on the intervals $(-\infty, -\frac{4}{3})$ and $(2, \infty)$ and decreasing on the interval $(-\frac{4}{3}, 2)$. By the First Derivative Test, it follows that f has a local maximum value at $-\frac{4}{3}$ and a local minimum value at 2. The local maximum value is $f\left(-\frac{4}{3}\right) = \frac{203}{27}$, and the

local minimum value is $f(2) = -11$.

- (b) The second derivative of f is

$$f''(x) = 6x - 2.$$

Evaluating the second derivative at the critical numbers yields

$$f''\left(-\frac{4}{3}\right) = -10 < 0 \quad \text{and} \quad f''(2) = 10 > 0.$$

By the Second Derivative Test, it follows that f has a local maximum value at $-\frac{4}{3}$ and a local minimum value at 2. The local maximum value is $f\left(-\frac{4}{3}\right) = \frac{203}{27}$, and the

local minimum value is $f(2) = -11$.

14. Let $f(x) = x^2 - 24x^{2/3}$. The critical numbers of f occur where $f'(x) = 0$ or where $f'(x)$ does not exist. Now,

$$f'(x) = 2x - 16x^{-1/3} = \frac{2(x^{4/3} - 8)}{x^{1/3}},$$

so $\pm 4\sqrt[4]{2}$ and 0 are critical numbers of f .

- (a) To determine where $f'(x) > 0$ and $f'(x) < 0$, use the numbers 0 and $\pm 4\sqrt[4]{2}$ to divide the number line into four intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $2(x^{4/3} - 8)$	Sign of $x^{1/3}$	Sign of $f'(x)$	Conclusion
$(-\infty, -4\sqrt[4]{2})$	+	—	—	f is decreasing
$(-4\sqrt[4]{2}, 0)$	—	—	+	f is increasing
$(0, 4\sqrt[4]{2})$	—	+	—	f is decreasing
$(4\sqrt[4]{2}, \infty)$	+	+	+	f is increasing

Therefore, f is increasing on the intervals $(-4\sqrt[4]{2}, 0)$ and $(4\sqrt[4]{2}, \infty)$ and decreasing on the intervals $(-\infty, -4\sqrt[4]{2})$ and $(0, 4\sqrt[4]{2})$. By the First Derivative Test, it follows that f has a local maximum value at 0 and local minimum values at $\pm 4\sqrt[4]{2}$. The local maximum value is $f(0) = 0$, and the local minimum values are $f(-4\sqrt[4]{2}) = f(4\sqrt[4]{2}) = -32\sqrt{2}$.

- (b) The second derivative of f is

$$f''(x) = 2 + \frac{16}{3}x^{-4/3}.$$

Evaluating the second derivative at $-4\sqrt[4]{2}$ yields $f''(-4\sqrt[4]{2}) = 8/3 > 0$; by the Second Derivative Test, it follows that f has a local minimum value at $-4\sqrt[4]{2}$. Similarly, the second derivative at $4\sqrt[4]{2}$ yields $f''(4\sqrt[4]{2}) = 8/3 > 0$; by the Second Derivative Test, it follows that f has a local minimum value at $4\sqrt[4]{2}$. The local minimum values are $f(-4\sqrt[4]{2}) = f(4\sqrt[4]{2}) = -32\sqrt{2}$. The Second Derivative Test cannot be applied at $x = 0$ because $f'(x)$ does not exist at 0.

15. Let $f(x) = x^4 e^{-2x}$. The function f is differentiable everywhere, so critical numbers occur where $f'(x) = 0$. Now,

$$f'(x) = x^4 \cdot -2e^{-2x} + 4x^3 e^{-2x} = (4x^3 - 2x^4)e^{-2x} = 2x^3(2 - x)e^{-2x},$$

so 0 and 2 are the critical numbers of f

- (a) To determine where $f'(x) > 0$ and $f'(x) < 0$, use the numbers 0 and 2 to divide the number line into three intervals. The sign of $f'(x)$ is then determined on each interval, as shown in the following table.

Interval	Sign of $2x^3$	Sign of $(2 - x)e^{-2x}$	Sign of $f'(x)$	Conclusion
$(-\infty, 0)$	—	+	—	f is decreasing
$(0, 2)$	+	+	+	f is increasing
$(2, \infty)$	+	—	—	f is decreasing

Therefore, f is decreasing on the intervals $(-\infty, 0)$ and $(2, \infty)$ and increasing on the interval $(0, 2)$. By the First Derivative Test, it follows that f has a local minimum value at 0 and a local maximum value at 2. The local minimum value is $f(0) = 0$, and the local maximum value is $f(2) = 16e^{-4}$.

- (b) The second derivative of f is

$$f''(x) = -2(4x^3 - 2x^4)e^{-2x} + (12x^2 - 8x^3)e^{-2x} = (4x^4 - 16x^3 + 12x^2)e^{-2x}.$$

Evaluating the second derivative at the critical numbers yields

$$f''(0) = 0 \quad \text{and} \quad f''(2) = -16e^{-4} < 0.$$

By the Second Derivative Test, it follows that f has a local maximum value at 2; the local maximum value is $f(2) = 16e^{-4}$. The Second Derivative Test is inconclusive at 0.

16. Let $s = t^4 + 2t^3 - 36t^2$. The object moves to the right when $v(t) = s'(t) > 0$ and moves to the left when $v(t) = s'(t) < 0$. Now,

$$v(t) = s'(t) = 4t^3 + 6t^2 - 72t = 2t(2t^2 + 3t - 36),$$

so $v(t) = 0$ when $t = 0$ and when

$$t = \frac{-3 \pm \sqrt{3^2 - 4(2)(-36)}}{4} = \frac{-3 \pm 3\sqrt{33}}{4}.$$

Of these numbers, only $\frac{-3 + 3\sqrt{33}}{4} \approx 3.558$ is greater than zero. On the approximate interval $(0, 3.558)$, $v(t) < 0$ and the object is moving to the left; on the approximate interval $(3.558, \infty)$, $v(t) > 0$ and the object is moving to the right. Additionally, the velocity of the object is increasing when $a(t) = v'(t) > 0$ and is decreasing when $a(t) = v'(t) < 0$. Now

$$a(t) = v'(t) = 12t^2 + 12t - 72 = 12(t^2 + t - 6) = 12(t + 3)(t - 2).$$

On the interval $(0, 2)$, $a(t) < 0$; on the interval $(2, \infty)$, $a(t) > 0$. Therefore, the velocity of the object is decreasing on the interval $(0, 2)$, and the velocity is increasing on the interval $(2, \infty)$. The figures below illustrates the motion (top) and velocity (bottom) of the object.

17. Let $y = f(x) = -x^3 - x^2 + 2x$.

Step 1 The polynomial function f has a domain of all real numbers. $f(0) = 0$, so the y -intercept is 0. To find the x -intercepts, solve the equation $f(x) = 0$. Because

$$-x^3 - x^2 + 2x = -x(x^2 + x - 2) = -x(x - 1)(x + 2),$$

it follows the graph of f has three x -intercepts: -2 , 0 , and 1 .

Step 2 The graphs of polynomial functions do not have asymptotes, but the end behavior of the graph of f will resemble the power function $y = -x^3$.

Step 3 Now

$$\begin{aligned} f'(x) &= -3x^2 - 2x + 2; \text{ and} \\ f''(x) &= -6x - 2 = -2(3x + 1). \end{aligned}$$

The critical numbers of the polynomial function f occur where $f'(x) = 0$, so

$$x = \frac{2 \pm \sqrt{(-2)^2 - 4(-3)(2)}}{-6} = \frac{2 \pm 2\sqrt{7}}{-6} = \boxed{-\frac{1}{3} \pm \frac{1}{3}\sqrt{7}}$$

are the critical numbers. At the points

$$\left(-\frac{1}{3} - \frac{1}{3}\sqrt{7}, -\frac{20}{27} - \frac{14}{27}\sqrt{7}\right) \approx (-1.215, -2.113)$$

and

$$\left(-\frac{1}{3} + \frac{1}{3}\sqrt{7}, -\frac{20}{27} + \frac{14}{27}\sqrt{7}\right) \approx (0.549, 0.631),$$

the tangent lines are horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the critical numbers $-\frac{1}{3} \pm \frac{1}{3}\sqrt{7}$ to divide the number line into three intervals.

Interval	Sign of f'	Conclusion
$(-\infty, -\frac{1}{3} - \frac{1}{3}\sqrt{7})$	$-$	f is decreasing on $(-\infty, -\frac{1}{3} - \frac{1}{3}\sqrt{7})$
$(-\frac{1}{3} - \frac{1}{3}\sqrt{7}, -\frac{1}{3} + \frac{1}{3}\sqrt{7})$	$+$	f is increasing on $(-\frac{1}{3} - \frac{1}{3}\sqrt{7}, -\frac{1}{3} + \frac{1}{3}\sqrt{7})$
$(-\frac{1}{3} + \frac{1}{3}\sqrt{7}, \infty)$	$-$	f is decreasing on $(-\frac{1}{3} + \frac{1}{3}\sqrt{7}, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local minimum value at $-\frac{1}{3} - \frac{1}{3}\sqrt{7}$ and a local maximum value at $-\frac{1}{3} + \frac{1}{3}\sqrt{7}$. The

$$\text{local minimum value is } f\left(-\frac{1}{3} - \frac{1}{3}\sqrt{7}\right) = -\frac{20}{27} - \frac{14}{27}\sqrt{7},$$

while the

$$\text{local maximum value is } f\left(-\frac{1}{3} + \frac{1}{3}\sqrt{7}\right) = -\frac{20}{27} + \frac{14}{27}\sqrt{7}.$$

Step 6 The second derivative is equal to zero at $x = -\frac{1}{3}$. Use this number to divide the number line into two intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, -\frac{1}{3})$	$+$	f is concave up on $(-\infty, -\frac{1}{3})$
$(-\frac{1}{3}, \infty)$	$-$	f is concave down on $(-\frac{1}{3}, \infty)$

The concavity of f changes at $-\frac{1}{3}$, so the point $\left(-\frac{1}{3}, -\frac{20}{27}\right)$ is a point of inflection.

Step 7 The figure below displays the graph of f . Local extreme values are highlighted by closed circles, and the point of inflection is highlighted by a closed square.

18. Let $y = f(x) = x^{1/3}(x^2 - 9) = x^{7/3} - 9x^{1/3}$.

Step 1 The domain of f is the set of all real numbers. Solving

$$x^{1/3}(x^2 - 9) = 0,$$

yields 0 and ± 3 as the x -intercepts; the y -intercept is $f(0) = 0$.

Step 2 Because

$$\lim_{x \rightarrow \pm\infty} [x^{1/3}(x^2 - 9)] = \lim_{x \rightarrow \pm\infty} \left[x^{7/3} \left(1 - \frac{9}{x^2} \right) \right] = \pm\infty,$$

the graph of f does not have a horizontal asymptote. The graph also has no vertical asymptotes because f is defined for all x .

Step 3 Now,

$$\begin{aligned} f'(x) &= \frac{7}{3}x^{4/3} - 3x^{-2/3} = \frac{7x^2 - 9}{3x^{2/3}}; \text{ and} \\ f''(x) &= \frac{28}{9}x^{1/3} + 2x^{-5/3} = \frac{28x^2 + 18}{9x^{5/3}}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is equal to 0 when $x = \pm \frac{3\sqrt{7}}{7}$ and does not exist when $x = 0$. Therefore, 0 and $\pm \frac{3\sqrt{7}}{7}$ are critical numbers of f . At the point $(0, 0)$, the tangent line is vertical; at the points

$$\left(-\frac{3\sqrt{7}}{7}, \frac{54}{49} \sqrt[6]{151,263} \right) \approx (-1.134, 8.044) \quad \text{and} \quad \left(\frac{3\sqrt{7}}{7}, -\frac{54}{49} \sqrt[6]{151,263} \right) \approx (1.134, -8.044),$$

the tangent lines are horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the numbers 0 and $\pm \frac{3\sqrt{7}}{7}$ to divide the number line into four intervals.

Interval	Sign of f'	Conclusion
$(-\infty, -\frac{3\sqrt{7}}{7})$	+	f is increasing on $(-\infty, -\frac{3\sqrt{7}}{7})$
$(-\frac{3\sqrt{7}}{7}, 0)$	-	f is decreasing on $(-\frac{3\sqrt{7}}{7}, 0)$
$(0, \frac{3\sqrt{7}}{7})$	-	f is decreasing on $(0, \frac{3\sqrt{7}}{7})$
$(\frac{3\sqrt{7}}{7}, \infty)$	+	f is increasing on $(\frac{3\sqrt{7}}{7}, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local maximum value at $-\frac{3\sqrt{7}}{7}$ and a local minimum value at $\frac{3\sqrt{7}}{7}$. The

local maximum value is $f\left(-\frac{3\sqrt{7}}{7}\right) = \frac{54}{49} \sqrt[6]{151,263}$,

and the

local minimum value is $f\left(\frac{3\sqrt{7}}{7}\right) = -\frac{54}{49} \sqrt[6]{151,263}$.

Step 6 The second derivative is never equal to zero and does not exist when $x = 0$. Use this number to divide the number line into two intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, 0)$	-	f is concave down on $(-\infty, 0)$
$(0, \infty)$	+	f is concave up on $(0, \infty)$

The concavity of f changes at 0, so the point $(0, 0)$ is a point of inflection.

Step 7 The figure below displays the graph of f . The local extreme values are highlighted by closed circles, and the point of inflection is highlighted by a closed square.

19. Let $y = f(x) = xe^x$.

Step 1 The domain of f is the set of all real numbers. The x -intercept is 0, and the y -intercept is $f(0) = 0$.

Step 2 Because the domain of f is the set of all real numbers, the graph of f has no vertical asymptotes. To determine if there is a horizontal asymptote, consider the limits at infinity and at negative infinity:

$$\lim_{x \rightarrow -\infty} xe^x = \lim_{x \rightarrow -\infty} \frac{x}{e^{-x}} = \lim_{x \rightarrow -\infty} \frac{1}{-e^{-x}} = 0$$

and

$$\lim_{x \rightarrow \infty} xe^x = \infty,$$

where L'Hôpital's Rule was used in the first limit. Therefore, the graph of f has the line $y = 0$ as a horizontal asymptote as $x \rightarrow -\infty$ and no horizontal asymptote as $x \rightarrow \infty$.

Step 3 Now,

$$\begin{aligned} f'(x) &= xe^x + e^x = e^x(x+1); \text{ and} \\ f''(x) &= e^x + e^x(x+1) = e^x(x+2). \end{aligned}$$

The function f is differentiable everywhere, so the critical numbers of f occur where $f'(x) = 0$, which is when $x = -1$. At the point $\left(-1, -\frac{1}{e}\right)$, the tangent line is horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the number -1 to divide the number line into two intervals.

Interval	Sign of f'	Conclusion
$(-\infty, -1)$	$-$	f is decreasing on $(-\infty, -1)$
$(-1, \infty)$	$+$	f is increasing on $(-1, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local minimum value at -1 . The local minimum value is $f(-1) = -\frac{1}{e}$.

Step 6 The second derivative exists everywhere and is equal to zero when $x = -2$. Use this number to divide the number line into two intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, -2)$	$-$	f is concave down on $(-\infty, -2)$
$(-2, \infty)$	$+$	f is concave up on $(-2, \infty)$

The concavity of f changes at -2 , so the point $\left(-2, -\frac{2}{e^2}\right)$ is a point of inflection.

Step 7 The figure below displays the graph of f . The local extreme value is highlighted by a closed circle, and the point of inflection is highlighted by a closed square.

20. Let $y = f(x) = \frac{x-3}{x^2-4}$.

Step 1 The domain of the rational function f is the set $\{x|x \neq \pm 2\}$. The x -intercept is 3, and the y -intercept is $f(0) = \frac{3}{4}$.

Step 2 The degree of the numerator is less than the degree of the denominator, so the graph of f has a horizontal asymptote. Because

$$\lim_{x \rightarrow \pm\infty} \frac{x-3}{x^2-4} = \lim_{x \rightarrow \pm\infty} \frac{x-3}{x^2-4} \cdot \frac{\frac{1}{x^2}}{\frac{1}{x^2}} = \lim_{x \rightarrow \pm\infty} \frac{\frac{1}{x} - \frac{3}{x^2}}{1 - \frac{4}{x^2}} = 0,$$

the line $y = 0$ is a horizontal asymptote. To identify vertical asymptotes, check the one-sided limits at those values for x that are not in the domain of f . As

$$\lim_{x \rightarrow -2^-} \frac{x-3}{x^2-4} = -\infty \quad \text{and} \quad \lim_{x \rightarrow -2^+} \frac{x-3}{x^2-4} = \infty,$$

and

$$\lim_{x \rightarrow 2^-} \frac{x-3}{x^2-4} = \infty \quad \text{and} \quad \lim_{x \rightarrow 2^+} \frac{x-3}{x^2-4} = -\infty,$$

the lines $x = \pm 2$ are vertical asymptotes.

Step 3 Now

$$\begin{aligned} f'(x) &= \frac{d}{dx} \left(\frac{x-3}{x^2-4} \right) = \frac{(x^2-4) \cdot 1 - (x-3) \cdot 2x}{(x^2-4)^2} = -\frac{x^2-6x+4}{(x^2-4)^2}; \text{ and} \\ f''(x) &= \frac{d}{dx} \left[-\frac{x^2-6x+4}{(x^2-4)^2} \right] = -\frac{(x^2-4)^2 \cdot (2x-6) - (x^2-6x+4) \cdot 2(x^2-4)(2x)}{(x^2-4)^4} \\ &= -\frac{(2x-6)(x^2-4) - 4x(x^2-6x+4)}{(x^2-4)^3} = \frac{2(x^3-9x^2+12x-12)}{(x^2-4)^3}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is equal to 0 when $x = 3 \pm \sqrt{5}$ and does not exist when $x = \pm 2$. However, ± 2 are not in the domain of f , so ± 2 are not critical numbers. Therefore, $\boxed{3 \pm \sqrt{5}}$ are the critical numbers of f . At the points

$$\left(3 - \sqrt{5}, \frac{15 + 5\sqrt{5}}{40}\right) \approx (0.764, 0.655) \quad \text{and} \quad \left(3 + \sqrt{5}, \frac{15 - 5\sqrt{5}}{40}\right) \approx (5.236, 0.095),$$

the tangent lines are horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the numbers ± 2 and $3 \pm \sqrt{5}$ to divide the number line into five intervals.

Interval	Sign of f'	Conclusion
$(-\infty, -2)$	—	f is decreasing on $(-\infty, -2)$
$(-2, 3 - \sqrt{5})$	—	f is decreasing on $(-2, 3 - \sqrt{5})$
$(3 - \sqrt{5}, 2)$	+	f is increasing on $(3 - \sqrt{5}, 2)$
$(2, 3 + \sqrt{5})$	+	f is increasing on $(2, 3 + \sqrt{5})$
$(3 + \sqrt{5}, \infty)$	—	f is decreasing on $(3 + \sqrt{5}, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local minimum value at $3 - \sqrt{5}$ and a local maximum value at $3 + \sqrt{5}$. The

$$\boxed{\text{local minimum value is } f(3 - \sqrt{5}) = \frac{15 + 5\sqrt{5}}{40}},$$

and the

$$\boxed{\text{local maximum value is } f(3 + \sqrt{5}) = \frac{15 - 5\sqrt{5}}{40}}.$$

Step 6 The second derivative is equal to zero when $x \approx 7.634$ (this value was obtained using the computer algebra system *Maple*) and does not exist when $x = \pm 2$. Use these numbers to divide the number line into four intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, -2)$	—	f is concave down on $(-\infty, -2)$
$(-2, 2)$	+	f is concave up on $(-2, 2)$
$(2, 7.634)$	—	f is concave down on $(2, 7.634)$
$(7.634, \infty)$	+	f is concave up on $(7.634, \infty)$

The concavity of f changes at approximately 7.634, so the point $\boxed{(7.634, 0.085)}$ is a point of inflection. Although the concavity of f changes at ± 2 , there is no point of inflection at ± 2 because ± 2 are not in the domain of f .

Step 7 The figure below displays the graph of f . The local extreme values are highlighted by closed circles and the inflection point is highlighted by a closed square.

21. Let $y = f(x) = x\sqrt{x-3}$.

Step 1 The domain of f is given by the solution to the inequality $x-3 \geq 0$, that is, the set $\{x|x \geq 3\}$.

The x -intercept is 3, and there is no y -intercept because 0 is not in the domain of f .

Step 2 Because

$$\lim_{x \rightarrow \infty} x\sqrt{x-3} = \infty,$$

the graph of f does not have a horizontal asymptote. The graph also does not have any vertical asymptotes.

Step 3 Now,

$$\begin{aligned} f'(x) &= \frac{d}{dx}(x\sqrt{x-3}) = x \cdot \frac{1}{2\sqrt{x-3}} + \sqrt{x-3} = \frac{3x-6}{2\sqrt{x-3}}; \text{ and} \\ f''(x) &= \frac{d}{dx} \left(\frac{3x-6}{2\sqrt{x-3}} \right) = \frac{2\sqrt{x-3} \cdot 3 - (3x-6) \cdot (x-3)^{-1/2}}{4(x-3)} \\ &= \frac{6(x-3) - (3x-6)}{4(x-3)^{3/2}} = \frac{3x-12}{4(x-3)^{3/2}}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is equal to 0 when $x = 2$ and does not exist when $x = 3$; however, 2 is not in the domain of f , so 2 is not a critical number. Therefore, 3 is the only critical number of f . At the point $(3, 0)$, the tangent line is vertical.

Step 4 Because $f'(x) > 0$ for all $x > 3$, f is increasing on the interval $(3, \infty)$.

Step 5 Because the only critical number of f is an endpoint of the domain of f , f has no local extreme values.

Step 6 The second derivative exists for $x > 3$ and is equal to zero when $x = 4$. Use this number to divide the number line into two intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(3, 4)$	$-$	f is concave down on $(3, 4)$
$(4, \infty)$	$+$	f is concave up on $(4, \infty)$

The concavity of f changes at 4, so the point $(4, 4)$ is a point of inflection.

Step 7 The figure below displays the graph of f . The point of inflection is highlighted by a closed square.

22. Let $y = f(x) = x^3 - 3 \ln x$.

Step 1 The domain of f is the set $\{x|x > 0\}$. There are no x -intercepts because $x^3 > \ln x^3 = 3 \ln x$ for all $x > 0$, and there is also no y -intercept because the function is not defined at 0.

Step 2 Because

$$\lim_{x \rightarrow \infty} x^3 = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} (3 \ln x) = \infty,$$

the expression $x^3 - 3 \ln x$ is an indeterminate form at ∞ of the type $\infty - \infty$. Rewrite

$$x^3 - 3 \ln x \quad \text{as} \quad x^3 \left(1 - \frac{3 \ln x}{x^3} \right).$$

Now, the expression $\frac{3 \ln x}{x^3}$ is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$; by L'Hôpital's Rule,

$$\lim_{x \rightarrow \infty} \frac{3 \ln x}{x^3} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx}(3 \ln x)}{\frac{d}{dx}x^3} = \lim_{x \rightarrow \infty} \frac{\frac{3}{x}}{3x^2} = 0.$$

Therefore,

$$\lim_{x \rightarrow \infty} \left(1 - \frac{3 \ln x}{x^3} \right) = 1 \quad \text{and} \quad \lim_{x \rightarrow \infty} (x^3 - 3 \ln x) = \lim_{x \rightarrow \infty} \left[x^3 \left(1 - \frac{3 \ln x}{x^3} \right) \right] = \infty,$$

so the graph of f has no horizontal asymptote. On the other hand,

$$\lim_{x \rightarrow 0^+} (x^3 - 3 \ln x) = \infty,$$

so the line $x = 0$ is a vertical asymptote.

Step 3 Now,

$$\begin{aligned} f'(x) &= 3x^2 - \frac{3}{x} = \frac{3(x^3 - 1)}{x}; \text{ and} \\ f''(x) &= 6x + \frac{3}{x^2} = \frac{6x^3 + 3}{x^2}. \end{aligned}$$

The critical numbers of f occur where $f'(x) = 0$ and where $f'(x)$ does not exist. $f'(x)$ is equal to zero when $x = 1$ and does not exist when $x = 0$; however, 0 is not a critical number because 0 is not in the domain of f . Therefore, 1 is the only critical number. At the point (1,1), the tangent line is horizontal.

Step 4 To apply the Increasing/Decreasing Function Test, use the number 1 to divide $(0, \infty)$ into two intervals.

Interval	Sign of f'	Conclusion
$(0, 1)$	$-$	f is decreasing on $(0, 1)$
$(1, \infty)$	$+$	f is increasing on $(1, \infty)$

Step 5 By the First Derivative Test and the information in the table above, f has a local minimum value at 1. The local maximum value is $f(1) = 1$.

Step 6 Because $f''(x) > 0$ for all $x > 0$, f is concave up on the interval $(0, \infty)$.

Step 7 The figure below displays the graph of f . The local extreme value is highlighted by a closed circle.

23. Let $f(x) = x^4 + 12x^2 + 36x - 11$. Then

$$\begin{aligned} f'(x) &= 4x^3 + 24x + 36; \text{ and} \\ f''(x) &= 12x^2 + 24. \end{aligned}$$

- (a) Using the computer algebra system *Maple*, it is found that $f'(x) = 0$ for $x \approx -1.207$. For $x < -1.207$, $f'(x) < 0$, while for $x > -1.207$, $f'(x) > 0$. Therefore, f is

decreasing on the approximate interval $(-\infty, -1.207)$

and

increasing on the approximate interval $(-1.207, \infty)$.

- (b) Because $f''(x) \geq 24 > 0$ for all x , f is concave up on the interval $(-\infty, \infty)$.

- (c) Because the concavity of f does not change, f has no points of inflection.

24. Let $f(x) = 3x^4 - 2x^3 - 24x^2 - 7x + 2$. Then

$$\begin{aligned} f'(x) &= 12x^3 - 6x^2 - 48x - 7; \text{ and} \\ f''(x) &= 36x^2 - 12x - 48 = 12(3x^2 - x - 4) = 12(3x - 4)(x + 1). \end{aligned}$$

- (a) Using the computer algebra system *Maple*, it is found that $f'(x) = 0$ for $x \approx -1.677$, $x \approx -0.149$, and $x \approx 2.327$. To apply the Increasing/Decreasing Function Test, use the numbers -1.677 , -0.149 , and 2.327 to divide the number line into four intervals.

Interval	Sign of f'	Conclusion
$(-\infty, -1.677)$	$-$	f is decreasing on $(-\infty, -1.677)$
$(-1.677, -0.149)$	$+$	f is increasing on $(-1.677, -0.149)$
$(-0.149, 2.327)$	$-$	f is decreasing on $(-0.149, 2.327)$
$(2.327, \infty)$	$+$	f is increasing on $(2.327, \infty)$

- (b) The second derivative exists everywhere and is equal to zero when $x = -1$ and $x = \frac{4}{3}$. Use these numbers to divide the number line into three intervals, and determine the sign of f'' on each interval.

Interval	Sign of f''	Conclusion
$(-\infty, -1)$	$+$	f is concave up on $(-\infty, -1)$
$(-1, \frac{4}{3})$	$-$	f is concave down on $(-1, \frac{4}{3})$
$(\frac{4}{3}, \infty)$	$+$	f is concave up on $(\frac{4}{3}, \infty)$

- (c) The concavity of f changes at -1 and $\frac{4}{3}$, so the points $(-1, -10)$ and $(\frac{4}{3}, -\frac{1222}{27})$ are points of inflection.

25. Because $y' > 0$ and $y'' < 0$ for all x , the graph of $y = f(x)$ is always increasing and concave down.

- (A) This cannot be part of the graph of $y = f(x)$ because this graph segment is concave up.
 (B) This could be part of the graph of $y = f(x)$ because this graph segment is increasing and concave down.
 (C) This cannot be part of the graph of $y = f(x)$ because this graph segment is decreasing.
 (D) This cannot be part of the graph of $y = f(x)$ because this graph segment is decreasing.

Therefore, (B) could be a part of the graph of f .

26. Answers will vary. The figure below displays the graph of a function f with the following properties:
 $f(-3) = 2$; $f(-1) = -5$; $f(2) = -4$; $f(6) = -1$; $f'(-3) = f'(6) = 0$; $\lim_{x \rightarrow 0^-} f(x) = -\infty$; $\lim_{x \rightarrow 0^+} f(x) = \infty$;
 $f''(x) > 0$ if $x < -3$ or $0 < x < 4$; and $f''(x) < 0$ if $-3 < x < 0$ or $4 < x$.

27. Answers will vary. The figure below displays the graph of a function f with the following properties:
 $f(-2) = 2$; $f(5) = 1$; $f(0) = 0$; $f'(x) > 0$ if $x < -2$ or $5 < x$ and $f'(x) < 0$ if $-2 < x < 2$ or $2 < x < 5$;
 $f''(x) > 0$ if $x < 0$ or $2 < x$ and $f''(x) < 0$ if $0 < x < 2$; $\lim_{x \rightarrow 2^-} f(x) = -\infty$; $\lim_{x \rightarrow 2^+} f(x) = \infty$.

28. Let $f(x) = x\sqrt{x+1}$. We need to determine b such that

$$\frac{f(b) - f(0)}{b - 0} = f'(3).$$

Now,

$$\frac{f(b) - f(0)}{b - 0} = \frac{b\sqrt{b+1} - 0}{b} = \sqrt{b+1},$$

and

$$f'(x) = \frac{x}{2\sqrt{x+1}} + \sqrt{x+1} \quad \text{so} \quad f'(3) = \frac{3}{4} + 2 = \frac{11}{4}.$$

Therefore,

$$\sqrt{b+1} = \frac{11}{4} \quad \text{or} \quad b = \left(\frac{11}{4}\right)^2 - 1 = \boxed{\frac{105}{16}}.$$

29. Let x denote the side length in inches of the square cut from each corner of the base (see the diagram below, where all lengths are given in inches). When the sides are turned up, the resulting box will have a rectangular base measuring $24 - 2x$ inches by $36 - 2x$ inches and a height of x inches; the volume will therefore be

$$V = x(24 - 2x)(36 - 2x) = 4x^3 - 120x^2 + 864x.$$

To determine the domain of V , note that the length of each of the three sides of the box must be non-negative. This requires $x \geq 0$, $24 - 2x \geq 0$, and $36 - 2x \geq 0$. The solution of this set of three inequalities is $0 \leq x \leq 12$; it follows that the domain of V is the closed interval $[0, 12]$. The function V is differentiable on the open interval $(0, 12)$, so the critical numbers occur where $V'(x) = 0$. Now,

$$V'(x) = 12x^2 - 240x + 864 = 12(x^2 - 20x + 72),$$

so the only critical number inside the open interval $(0, 12)$ is

$$x = \frac{20 - \sqrt{20^2 - 4(1)(72)}}{2} = \frac{20 - 4\sqrt{7}}{2} = 10 - 2\sqrt{7} \approx 4.708.$$

Note that

$$x = \frac{20 + \sqrt{20^2 - 4(1)(72)}}{2} = \frac{20 + 4\sqrt{7}}{2} = 10 + 2\sqrt{7} \approx 15.292$$

is not in the domain of V . Evaluating V at the endpoints of the interval $[0, 12]$ and at the critical number 4.708 yields

$$V(0) = 0, \quad V(4.708) \approx 1825.297, \quad \text{and} \quad V(12) = 0.$$

The largest volume is therefore achieved when $x = 10 - 2\sqrt{7} \approx 4.708$. Squares with a side length of $\boxed{10 - 2\sqrt{7} \approx 4.708 \text{ inches}}$ should be cut out to produce a box with maximum volume.

30. Because distance is non-negative, minimizing the square of the distance will produce the same result as minimizing the distance but does not require the use of square roots. Let D denote the square of the distance between an arbitrary point (x, y) on the graph of the parabola $y = \frac{1}{2}x^2$ and the point $(4, 1)$. Then

$$\begin{aligned} D &= (x - 4)^2 + (y - 1)^2 = (x - 4)^2 + \left(\frac{1}{2}x^2 - 1\right)^2 \\ &= x^2 - 8x + 16 + \frac{1}{4}x^4 - x^2 + 1 \\ &= \frac{1}{4}x^4 - 8x + 17. \end{aligned}$$

The domain of D is all real numbers, and because D is differentiable everywhere, the critical numbers of D occur where $D'(x) = 0$. Now,

$$D'(x) = x^3 - 8 = (x - 2)(x^2 + 2x + 4),$$

so $x = 2$ is the only critical number. Using the Second Derivative Test,

$$D''(x) = 3x^2 \quad \text{so} \quad D''(2) = 12 > 0$$

and D has a local minimum value at 2. Because $D''(x) \geq 0$ for all x , the local minimum is also an absolute minimum. The point $\left(2, \frac{1}{2}2^2\right) = (2, 2)$ on the graph of the parabola $y = \frac{1}{2}x^2$ is closest to the point $(4, 1)$.

31. All antiderivatives of the function $f(x) = 0$ are $F(x) = \boxed{C}$, where C is a constant.

32. All antiderivatives of the function $f(x) = x^{1/2}$ are

$$F(x) = \frac{x^{1/2+1}}{1/2+1} + C = \boxed{\frac{2}{3}x^{3/2} + C},$$

where C is a constant.

33. All antiderivatives of the function $f(x) = \cos x$ are $F(x) = \boxed{\sin x + C}$, where C is a constant.

34. All antiderivatives of the function $f(x) = \sec x \tan x$ are $F(x) = \boxed{\sec x + C}$, where C is a constant.

35. Using the Constant Multiple Rule, all antiderivatives of the function $f(x) = \frac{2}{x}$ are

$$F(x) = 2 \cdot \ln |x| + C = \boxed{2 \ln |x| + C},$$

where C is a constant.

36. Using the Constant Multiple Rule, all antiderivatives of the function $f(x) = -2x^{-3}$ are

$$F(x) = -2 \cdot \frac{x^{-3+1}}{-3+1} + C = \boxed{x^{-2} + C},$$

where C is a constant.

37. Using the Sum Rule and the Constant Multiple Rule, all antiderivatives of the function $f(x) = 4x^3 - 9x^2 + 10x - 3$ are

$$F(x) = 4 \cdot \frac{x^{3+1}}{3+1} - 9 \cdot \frac{x^{2+1}}{2+1} + 10 \cdot \frac{x^{1+1}}{1+1} - 3x + C = \boxed{x^4 - 3x^3 + 5x^2 - 3x + C},$$

where C is a constant.

38. Using the Sum Rule and the Constant Multiple Rule, all antiderivatives of the function $f(x) = e^x + \frac{4}{x}$ are

$$F(x) = e^x + 4 \cdot \ln |x| + C = \boxed{e^x + 4 \ln |x| + C},$$

where C is a constant.

39. Let $t = 0$ denote the time the box begins to move with a velocity v_0 , and let $v(t)$ and $s(t)$ denote the velocity and distance traveled by the box, respectively, t seconds after it begins to move. The general solution of the differential equation

$$\frac{dv}{dt} = a(t) = t^2(t - 3) = t^3 - 3t$$

is

$$v(t) = \frac{t^4}{4} - 3\frac{t^2}{2} + C_1 = \frac{1}{4}t^4 - \frac{3}{2}t^2 + C_1,$$

where C_1 is a constant. The initial condition $v(0) = v_0$ determines

$$v_0 = \frac{1}{4}0^4 - \frac{3}{2}0^2 + C_1 = C_1.$$

Next, the general solution of the differential equation

$$\frac{ds}{dt} = v(t) = \frac{1}{4}t^4 - \frac{3}{2}t^2 + v_0$$

is

$$s(t) = \frac{1}{4} \cdot \frac{t^5}{5} - \frac{3}{2} \cdot \frac{t^3}{3} + v_0 t + C_2 = \frac{1}{20}t^5 - \frac{1}{2}t^3 + v_0 t + C_2,$$

where C_2 is a constant. The initial condition $s(0) = 0$ determines

$$0 = \frac{1}{20}0^5 - \frac{1}{2}0^3 + v_0(0) + C_2 = C_2.$$

The box travels 10 cm in 2 s, so $s(2) = 10$ and

$$10 = \frac{1}{20}2^5 - \frac{1}{2}2^3 + 2v_0 = \frac{8}{5} - 4 + 2v_0.$$

Therefore,

$$v_0 = 7 - \frac{4}{5} = \boxed{\frac{31}{5} \text{ cm/s}}.$$

40. Let $t = 0$ denote the time the first object begins to fall. Additionally, let $v_1(t)$ and $s_1(t)$ denote the velocity and distance traveled, respectively, by the first object, and let $v_2(t)$ and $s_2(t)$ denote the velocity and distance traveled, respectively, by the second object. The initial conditions are $v_1(0) = 0$, $s_1(0) = 0$, $v_2(1) = 0$, and $s_2(1) = 0$. For the first object, the particular solution of the differential equation

$$\frac{dv_1}{dt} = a = -9.8$$

with the initial condition $v_1(0) = 0$ is $v_1(t) = -9.8t$, and the particular solution of the differential equation

$$\frac{ds_1}{dt} = v_1(t) = -9.8t$$

with the initial condition $s_1(0) = 0$ is $s_1(t) = -4.9t^2$. For the second object, the particular solution of the differential equation

$$\frac{dv_2}{dt} = a = -9.8$$

with the initial condition $v_2(1) = 0$ is $v_2(t) = -9.8t + 9.8$, and the particular solution of the differential equation

$$\frac{ds_2}{dt} = v_2(t) = -9.8t + 9.8$$

with the initial condition $s_2(1) = 0$ is $s_2(t) = -4.9t^2 + 9.8t - 4.9$. The two objects will be 10 m apart when $s_2(t) - s_1(t) = 10$; that is, when

$$-4.9t^2 + 9.8t - 4.9 - (-4.9t^2) = 9.8t - 4.9 = 10,$$

or

$$t = \frac{14.9}{9.8} \approx \boxed{1.52 \text{ s}}.$$

41. Because

$$\lim_{x \rightarrow 0} (xe^{3x} - x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} [1 - \cos(2x)] = 0,$$

the expression $\frac{xe^{3x} - x}{1 - \cos(2x)}$ is an $\boxed{\text{indeterminate form at 0 of the type } \frac{0}{0}}$.

42. Because

$$\lim_{x \rightarrow 0^-} \frac{1}{x} = -\infty \quad \text{and} \quad \lim_{x \rightarrow 0^-} \tan x = 0,$$

while

$$\lim_{x \rightarrow 0^+} \frac{1}{x} = \infty \quad \text{and} \quad \lim_{x \rightarrow 0^+} \tan x = 0,$$

the expression $\left(\frac{1}{x}\right)^{\tan x}$ is an $\boxed{\text{indeterminate form at 0 of the type } \infty^0}$.

43. Because

$$\lim_{x \rightarrow 0} \frac{1}{x^2} = \infty \quad \text{and} \quad \lim_{x \rightarrow 0} \frac{1}{x^2 \sec x} = \infty,$$

the expression $\frac{1}{x^2} - \frac{1}{x^2 \sec x}$ is an $\boxed{\text{indeterminate form at 0 of the type } \infty - \infty}$.

44. Because

$$\lim_{x \rightarrow 0} (\tan x - x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} (x - \sin x) = 0,$$

the expression $\frac{\tan x - x}{x - \sin x}$ is an $\boxed{\text{indeterminate form at 0 of the type } \frac{0}{0}}$.

45. Rewrite

$$\frac{\sec^2 x}{\sec^2(3x)} \quad \text{as} \quad \frac{\cos^2(3x)}{\cos^2 x}.$$

Because

$$\lim_{x \rightarrow \pi/2} [\cos^2(3x)] = 0 \quad \text{and} \quad \lim_{x \rightarrow \pi/2} \cos^2 x = 0,$$

the expression $\frac{\cos^2(3x)}{\cos^2 x}$ is an indeterminate form at $\pi/2$ of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow \pi/2} \frac{\cos^2(3x)}{\cos^2 x} = \lim_{x \rightarrow \pi/2} \frac{\frac{d}{dx} \cos^2(3x)}{\frac{d}{dx} \cos^2 x} = \lim_{x \rightarrow \pi/2} \frac{-6 \cos(3x) \sin(3x)}{-2 \cos x \sin x} = \lim_{x \rightarrow \pi/2} \frac{3 \sin(6x)}{\sin(2x)}.$$

Now,

$$\lim_{x \rightarrow \pi/2} [3 \sin(6x)] = 0 \quad \text{and} \quad \lim_{x \rightarrow \pi/2} \sin(2x) = 0,$$

so the expression $\frac{3 \sin(6x)}{\sin(2x)}$ is an indeterminate form at $\pi/2$ of the type $\frac{0}{0}$. Using L'Hôpital's Rule again,

$$\lim_{x \rightarrow \pi/2} \frac{\cos^2(3x)}{\cos^2 x} = \lim_{x \rightarrow \pi/2} \frac{3 \sin(6x)}{\sin(2x)} = \lim_{x \rightarrow \pi/2} \frac{\frac{d}{dx} [3 \sin(6x)]}{\frac{d}{dx} \sin(2x)} = \lim_{x \rightarrow \pi/2} \frac{18 \cos(6x)}{2 \cos(2x)} = \frac{18(-1)}{2(-1)} = 9.$$

Therefore,

$$\lim_{x \rightarrow \pi/2} \frac{\sec^2 x}{\sec^2(3x)} = \lim_{x \rightarrow \pi/2} \frac{\cos^2(3x)}{\cos^2 x} = \boxed{9}.$$

46. Because

$$\lim_{x \rightarrow 0} \frac{2}{\sin^2 x} = \infty \quad \text{and} \quad \lim_{x \rightarrow 0} \frac{1}{1 - \cos x} = \infty,$$

the expression $\frac{2}{\sin^2 x} - \frac{1}{1 - \cos x}$ is an indeterminate form at 0 of the type $\infty - \infty$. Rewrite

$$\frac{2}{\sin^2 x} - \frac{1}{1 - \cos x} \quad \text{as} \quad \frac{2 - 2 \cos x - \sin^2 x}{(1 - \cos x) \sin^2 x},$$

which is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\begin{aligned} \lim_{x \rightarrow 0} \left[\frac{2}{\sin^2 x} - \frac{1}{1 - \cos x} \right] &= \lim_{x \rightarrow 0} \frac{2 - 2 \cos x - \sin^2 x}{(1 - \cos x) \sin^2 x} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx} (2 - 2 \cos x - \sin^2 x)}{\frac{d}{dx} [(1 - \cos x) \sin^2 x]} \\ &= \lim_{x \rightarrow 0} \frac{2 \sin x - 2 \sin x \cos x}{(1 - \cos x) \cdot 2 \sin x \cos x + \sin^3 x} = \lim_{x \rightarrow 0} \frac{2 - 2 \cos x}{2(1 - \cos x) \cos x + \sin^2 x} \\ &= \lim_{x \rightarrow 0} \frac{2 - 2 \cos x}{1 + 2 \cos x - 3 \cos^2 x}. \end{aligned}$$

Now,

$$\lim_{x \rightarrow 0} (2 - 2 \cos x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} (1 + 2 \cos x - 3 \cos^2 x) = 0,$$

so the expression $\frac{2 - 2 \cos x}{1 + 2 \cos x - 3 \cos^2 x}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule again,

$$\begin{aligned} \lim_{x \rightarrow 0} \left[\frac{2}{\sin^2 x} - \frac{1}{1 - \cos x} \right] &= \lim_{x \rightarrow 0} \frac{2 - 2 \cos x}{1 + 2 \cos x - 3 \cos^2 x} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx} (2 - 2 \cos x)}{\frac{d}{dx} (1 + 2 \cos x - 3 \cos^2 x)} \\ &= \lim_{x \rightarrow 0} \frac{2 \sin x}{-2 \sin x + 6 \cos x \sin x} = \lim_{x \rightarrow 0} \frac{1}{3 \cos x - 1} = \boxed{\frac{1}{2}}. \end{aligned}$$

47. Because

$$\lim_{x \rightarrow 0} (e^x - e^{-x}) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} \sin x = 0,$$

the expression $\frac{e^x - e^{-x}}{\sin x}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 0} \frac{e^x - e^{-x}}{\sin x} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx} (e^x - e^{-x})}{\frac{d}{dx} \sin x} = \lim_{x \rightarrow 0} \frac{e^x + e^{-x}}{\cos x} = \frac{1 + 1}{1} = \boxed{2}.$$

48. Because

$$\lim_{x \rightarrow 0^-} x = 0 \quad \text{and} \quad \lim_{x \rightarrow 0^-} \cot(\pi x) = -\infty,$$

the expression $x \cot(\pi x)$ is an indeterminate form at 0^- of the type $0 \cdot \infty$. Rewrite

$$x \cot(\pi x) \quad \text{as} \quad \frac{x}{\tan(\pi x)},$$

which is an indeterminate form at 0^- of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 0^-} [x \cot(\pi x)] = \lim_{x \rightarrow 0^-} \frac{x}{\tan(\pi x)} = \lim_{x \rightarrow 0^-} \frac{\frac{d}{dx} x}{\frac{d}{dx} \tan(\pi x)} = \lim_{x \rightarrow 0^-} \frac{1}{\pi \sec^2(\pi x)} = \boxed{\frac{1}{\pi}}.$$

49. Because

$$\lim_{x \rightarrow 0} (\tan x + \sec x - 1) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} (\tan x - \sec x + 1) = 0,$$

the expression $\frac{\tan x + \sec x - 1}{\tan x - \sec x + 1}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 0} \frac{\tan x + \sec x - 1}{\tan x - \sec x + 1} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx}(\tan x + \sec x - 1)}{\frac{d}{dx}(\tan x - \sec x + 1)} = \lim_{x \rightarrow 0} \frac{\sec^2 x + \sec x \tan x}{\sec^2 x - \sec x \tan x} = \frac{1 + 0}{1 - 0} = \boxed{1}.$$

50. If $a = 0$, then

$$\lim_{x \rightarrow a} \frac{ax - x^2}{a^4 - 2a^3x + 2ax^3 - x^4} = \lim_{x \rightarrow 0} \frac{-x^2}{-x^4} = \lim_{x \rightarrow 0} \frac{1}{x^2} = \boxed{\infty}.$$

Suppose that $a \neq 0$. Note

$$\lim_{x \rightarrow a} (a^4 - 2a^3x + 2ax^3 - x^4) = 0.$$

Because $a^4 - 2a^3x + 2ax^3 - x^4$ is a polynomial in x , the only way that the limit of this expression as x approaches a can be equal to zero is for the expression to have a factor of $a - x$. Factoring yields

$$a^4 - 2a^3x + 2ax^3 - x^4 = (a - x)(a^3 - a^2x - ax^2 + x^3).$$

Now, substituting $x = a$ into $a^3 - a^2x - ax^2 + x^3$ again produces zero, so this latter expression must also contain a factor of $a - x$. Continuing to factor,

$$\begin{aligned} a^4 - 2a^3x + 2ax^3 - x^4 &= (a - x)(a^3 - a^2x - ax^2 + x^3) \\ &= (a - x)(a - x)(a^2 - x^2) \\ &= (a - x)(a - x)(a - x)(a + x) = (a - x)^3(a + x). \end{aligned}$$

Therefore, for $x \neq a$,

$$\frac{ax - x^2}{a^4 - 2a^3x + 2ax^3 - x^4} = \frac{x(a - x)}{(a - x)^3(a + x)} = \frac{x}{(a - x)^2(a + x)}.$$

Finally, because

$$\frac{x}{a + x} \rightarrow \frac{a}{2a} = \frac{1}{2} \quad \text{as} \quad x \rightarrow a,$$

it follows that

$$\lim_{x \rightarrow a} \frac{ax - x^2}{a^4 - 2a^3x + 2ax^3 - x^4} = \lim_{x \rightarrow a} \frac{x}{(a - x)^2(a + x)} = \boxed{\infty}.$$

51. Because

$$\lim_{x \rightarrow 0} (x - \sin x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} x^3 = 0,$$

the expression $\frac{x - \sin x}{x^3}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 0} \frac{x - \sin x}{x^3} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx}(x - \sin x)}{\frac{d}{dx}x^3} = \lim_{x \rightarrow 0} \frac{1 - \cos x}{3x^2}.$$

Now,

$$\lim_{x \rightarrow 0} (1 - \cos x) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} (3x^2) = 0,$$

so the expression $\frac{1 - \cos x}{3x^2}$ is also an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule again,

$$\lim_{x \rightarrow 0} \frac{x - \sin x}{x^3} = \lim_{x \rightarrow 0} \frac{1 - \cos x}{3x^2} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx}(1 - \cos x)}{\frac{d}{dx}(3x^2)} = \lim_{x \rightarrow 0} \frac{\sin x}{6x} = \frac{1}{6} \lim_{x \rightarrow 0} \frac{\sin x}{x} = \frac{1}{6} \cdot 1 = \boxed{\frac{1}{6}}.$$

52. Rewrite

$$\frac{\tan x - \sin x}{\sin^3 x} = \frac{\sec x - 1}{\sin^2 x}.$$

Because

$$\lim_{x \rightarrow 0} (\sec x - 1) = 0 \quad \text{and} \quad \lim_{x \rightarrow 0} \sin^2 x = 0,$$

the expression $\frac{\sec x - 1}{\sin^2 x}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\begin{aligned} \lim_{x \rightarrow 0} \frac{\tan x - \sin x}{\sin^3 x} &= \lim_{x \rightarrow 0} \frac{\sec x - 1}{\sin^2 x} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx}(\sec x - 1)}{\frac{d}{dx} \sin^2 x} \\ &= \lim_{x \rightarrow 0} \frac{\sec x \tan x}{2 \sin x \cos x} \\ &= \lim_{x \rightarrow 0} \frac{1}{2 \cos^3 x} = \boxed{\frac{1}{2}}. \end{aligned}$$

53. Because

$$\lim_{x \rightarrow \infty} (1 + 4x) = \infty \quad \text{and} \quad \lim_{x \rightarrow \infty} \frac{2}{x} = 0,$$

the expression $(1 + 4x)^{2/x}$ is an indeterminate form at ∞ of the type ∞^0 . Let $y = (1 + 4x)^{2/x}$. Then

$$\ln y = \ln(1 + 4x)^{2/x} = \frac{2}{x} \ln(1 + 4x) = \frac{2 \ln(1 + 4x)}{x},$$

which is an indeterminate form at ∞ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow \infty} \ln y = \lim_{x \rightarrow \infty} \frac{2 \ln(1 + 4x)}{x} = \lim_{x \rightarrow \infty} \frac{\frac{d}{dx}[2 \ln(1 + 4x)]}{\frac{d}{dx}x} = \lim_{x \rightarrow \infty} \frac{\frac{8}{1+4x}}{1} = 0.$$

Because $\lim_{x \rightarrow \infty} \ln y = 0$, it follows that

$$\lim_{x \rightarrow \infty} y = \lim_{x \rightarrow \infty} (1 + 4x)^{2/x} = e^0 = \boxed{1}.$$

54. Because

$$\lim_{x \rightarrow 1^-} \frac{2}{x^2 - 1} = -\infty \quad \text{and} \quad \lim_{x \rightarrow 1^-} \frac{1}{x - 1} = -\infty,$$

while

$$\lim_{x \rightarrow 1^+} \frac{2}{x^2 - 1} = \infty \quad \text{and} \quad \lim_{x \rightarrow 1^+} \frac{1}{x - 1} = \infty,$$

the expression $\frac{2}{x^2 - 1} - \frac{1}{x - 1}$ is an indeterminate form at 1 of the type $\infty - \infty$. Rewrite

$$\frac{2}{x^2 - 1} - \frac{1}{x - 1} \quad \text{as} \quad \frac{2}{x^2 - 1} - \frac{x + 1}{x^2 - 1} = \frac{1 - x}{x^2 - 1} = -\frac{1}{1 + x}.$$

Therefore,

$$\lim_{x \rightarrow 1} \left[\frac{2}{x^2 - 1} - \frac{1}{x - 1} \right] = \lim_{x \rightarrow 1} \left(-\frac{1}{x + 1} \right) = -\frac{1}{2}.$$

Alternately, note that the expression $\frac{1 - x}{x^2 - 1}$ is an indeterminate form at 1 of the type $\frac{0}{0}$, and then use L'Hôpital's Rule to obtain

$$\lim_{x \rightarrow 1} \left[\frac{2}{x^2 - 1} - \frac{1}{x - 1} \right] = \lim_{x \rightarrow 1} \frac{\frac{d}{dx}(1 - x)}{\frac{d}{dx}(x^2 - 1)} = \lim_{x \rightarrow 1} \frac{-1}{2x} = \boxed{-\frac{1}{2}}.$$

55. Because

$$\lim_{x \rightarrow 4} (x^2 - 16) = 0 \quad \text{and} \quad \lim_{x \rightarrow 4} (x^2 + x - 20) = 0,$$

the expression $\frac{x^2 - 16}{x^2 + x - 20}$ is an indeterminate form at 0 of the type $\frac{0}{0}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 4} \frac{x^2 - 16}{x^2 + x - 20} = \lim_{x \rightarrow 4} \frac{\frac{d}{dx}(x^2 - 16)}{\frac{d}{dx}(x^2 + x - 20)} = \lim_{x \rightarrow 4} \frac{2x}{2x + 1} = \boxed{\frac{8}{9}}.$$

Alternately,

$$\lim_{x \rightarrow 4} \frac{x^2 - 16}{x^2 + x - 20} = \lim_{x \rightarrow 4} \frac{(x + 4)(x - 4)}{(x - 4)(x + 5)} = \lim_{x \rightarrow 4} \frac{x + 4}{x + 5} = \boxed{\frac{8}{9}}.$$

56. Because

$$\lim_{x \rightarrow 0^+} \cot x = \infty \quad \text{and} \quad \lim_{x \rightarrow 0^+} x = 0,$$

the expression $(\cot x)^x$ is an indeterminate form at 0^+ of the type ∞^0 . Let $y = (\cot x)^x$. Then

$$\ln y = \ln(\cot x)^x = x \ln(\cot x) = \frac{\ln(\cot x)}{x^{-1}},$$

which is an indeterminate form at 0^+ of the type $\frac{\infty}{\infty}$. Using L'Hôpital's Rule,

$$\lim_{x \rightarrow 0^+} \ln y = \lim_{x \rightarrow 0^+} \frac{\ln(\cot x)}{x^{-1}} = \lim_{x \rightarrow 0^+} \frac{\frac{d}{dx} \ln(\cot x)}{\frac{d}{dx} x^{-1}} = \lim_{x \rightarrow 0^+} \frac{\frac{-\csc^2 x}{\cot x}}{-x^{-2}} = \lim_{x \rightarrow 0^+} \frac{x^2}{\sin x \cos x}.$$

Now,

$$\lim_{x \rightarrow 0^+} x^2 = 0 \quad \text{and} \quad \lim_{x \rightarrow 0^+} (\sin x \cos x) = 0,$$

so the expression $\frac{x^2}{\sin x \cos x}$ is an indeterminate form at 0^+ of the type $\frac{0}{0}$. Using L'Hôpital's Rule again,

$$\lim_{x \rightarrow 0^+} \ln y = \lim_{x \rightarrow 0^+} \frac{x^2}{\sin x \cos x} = \lim_{x \rightarrow 0^+} \frac{\frac{d}{dx} x^2}{\frac{d}{dx} (\sin x \cos x)} = \lim_{x \rightarrow 0^+} \frac{2x}{-\sin^2 x + \cos^2 x} = 0.$$

Because $\lim_{x \rightarrow 0^+} \ln y = 0$, it follows that

$$\lim_{x \rightarrow 0^+} y = \lim_{x \rightarrow 0^+} (\cot x)^x = e^0 = \boxed{1}.$$

57. The general solution of the differential equation

$$\frac{dy}{dx} = e^x$$

is $y = e^x + C$, where C is a constant. Applying the boundary condition that when $x = 0$, then $y = 2$ yields

$$2 = e^0 + C = 1 + C \quad \text{so that} \quad C = 1.$$

The particular solution of the differential equation with the given boundary condition is therefore $\boxed{y = e^x + 1}$.

58. The general solution of the differential equation

$$\frac{dy}{dx} = \frac{1}{2} \sec x \tan x$$

is $y = \frac{1}{2} \sec x + C$, where C is a constant. Applying the boundary condition that when $x = 0$, then $y = 7$ yields

$$7 = \frac{1}{2} \sec 0 + C = \frac{1}{2} + C \quad \text{so that} \quad C = \frac{13}{2}.$$

The particular solution of the differential equation with the given boundary condition is therefore

$$\boxed{y = \frac{1}{2} \sec x + \frac{13}{2}}.$$

59. The general solution of the differential equation

$$\frac{dy}{dx} = \frac{2}{x}$$

is $y = 2 \ln |x| + C$, where C is a constant. Applying the boundary condition that when $x = 1$, then $y = 4$ yields

$$4 = 2 \ln 1 + C = C.$$

The particular solution of the differential equation with the given boundary condition is therefore

$$\boxed{y = 2 \ln |x| + 4}.$$

60. All the antiderivatives of $\frac{d^2y}{dx^2} = x^2 - 4$ are

$$\frac{dy}{dx} = \frac{1}{3}x^3 - 4x + C_1,$$

and all the antiderivatives of $\frac{dy}{dx} = \frac{1}{3}x^3 - 4x + C_1$ are

$$y = \frac{1}{3} \cdot \frac{x^4}{4} - 4 \cdot \frac{x^2}{2} + C_1x + C_2 = \frac{1}{12}x^4 - 2x^2 + C_1x + C_2,$$

where C_1 and C_2 are constants. Applying the boundary condition that when $x = 3$, then $y = 2$ yields

$$2 = \frac{1}{12}3^4 - 2(3)^2 + 3C_1 + C_2 \quad \text{so that} \quad 3C_1 + C_2 = \frac{53}{4}.$$

Next, applying the boundary condition that when $x = 2$, then $y = 2$ yields

$$2 = \frac{1}{12}2^4 - 2(2)^2 + 2C_1 + C_2 \quad \text{so that} \quad 2C_1 + C_2 = \frac{26}{3}.$$

Solving the system of linear equations

$$3C_1 + C_2 = \frac{53}{4} \quad \text{and} \quad 2C_1 + C_2 = \frac{26}{3}$$

gives

$$C_1 = \frac{55}{12} \quad \text{and} \quad C_2 = -\frac{1}{2}.$$

The particular solution of the differential equation with the given boundary conditions is therefore

$$y = \frac{1}{12}x^4 - 2x^2 + \frac{55}{12}x - \frac{1}{2}.$$

61. The cost of producing x items is $C(x) = 200 + 35x + 0.02x^2$ and each item can be sold for \$78, so the revenue produced by selling x items is $R(x) = 78x$. The profit generated by producing and selling x items is then

$$P(x) = R(x) - C(x) = 78x - (200 + 35x + 0.02x^2) = -200 + 43x - 0.02x^2.$$

The polynomial function P is differentiable everywhere, so the critical numbers of P occur where $P'(x) = 0$. Now,

$$P'(x) = 43 - 0.04x,$$

so $x = 1075$ is the only critical number. Using the Second Derivative Test,

$$P''(x) = -0.04 < 0$$

for all x , so P has both a local maximum and an absolute maximum at 1075. Therefore, 1075 items should be produced and sold to maximize profit.

62. Let sales of a new stereo system be given by

$$f(x) = \frac{5000}{1 + 5e^{-x}},$$

for $x \geq 0$, where x is measured in years. The sales *rate* will be maximum when $f'(x)$ is maximum. Now,

$$\begin{aligned} f'(x) &= \frac{25000e^{-x}}{(1 + 5e^{-x})^2}; \text{ and} \\ f''(x) &= \frac{(1 + 5e^{-x})^2(-25000e^{-x}) - (25000e^{-x}) \cdot 2(1 + 5e^{-x})(-5e^{-x})}{(1 + 5e^{-x})^4} \\ &= -25000e^{-x} \frac{1 + 5e^{-x} - 10e^{-x}}{(1 + 5e^{-x})^3} = -25000e^{-x} \frac{1 - 5e^{-x}}{(1 + 5e^{-x})^3}. \end{aligned}$$

$f''(x)$ exists everywhere and is equal to zero when $1 - 5e^{-x} = 0$; that is, when $x = \ln 5$. Because

$$f'(0) = \frac{25000}{36}, \quad f'(\ln 5) = \frac{25000}{20}, \quad \lim_{x \rightarrow \infty} f'(x) = 0,$$

and $\ln 5$ is the only critical number, f' has an absolute maximum at $\ln 5$. The sales rate is a maximum $\ln 5 \approx 1.609$ years after sales began, so the sales rate is a maximum in the second year.

63. Let $(x, \ln x)$ be the coordinates of the vertex of the rectangle on the graph of $y = \ln x$ with $0 < x < 1$. The area A of the rectangle is

$$A = -x \ln x,$$

where the negative sign is included because $\ln x < 0$ for $0 < x < 1$, and

$$A'(x) = -\left(x \cdot \frac{1}{x} + \ln x\right) = -(1 + \ln x).$$

$A'(x)$ exists everywhere on the interval $(0, 1)$ and is equal to zero when $x = e^{-1}$. Using the Second Derivative Test,

$$A''(x) = -\frac{1}{x} \quad \text{so} \quad A''(e^{-1}) = -e < 0,$$

and A has a local maximum at e^{-1} . Because $A''(x) < 0$ for all $0 < x < 1$, the local maximum is also an absolute maximum. Therefore, the area of the largest rectangle in the fourth quadrant that has three vertices on the coordinate axes and the fourth vertex on the graph of $y = \ln x$ is

$$A = -e^{-1} \ln e^{-1} = e^{-1} = \boxed{\frac{1}{e}}.$$

64. Let $t = 0$ denote the time that the motorcycle begins to accelerate, and let $s(t)$ represent the distance the motorcycle has traveled after t seconds. Because the motorcycle accelerates at a constant rate from 0 to 72 km/h in 10 s, its acceleration a is given by

$$a = \frac{72 \text{ km/h}}{10 \text{ s}} \cdot \frac{1000 \text{ m}}{1 \text{ km}} \cdot \frac{1 \text{ h}}{3600 \text{ s}} = 2 \text{ m/s}^2.$$

Solve the differential equation

$$\frac{dv}{dt} = a(t) = 2$$

for $v(t)$ to obtain $v(t) = 2t + C_1$, where C_1 is a constant. Apply the initial condition $v(0) = 0$ to determine

$$0 = 2(0) + C_1 = C_1,$$

so that $v(t) = 2t$. Next, solve the differential equation

$$\frac{ds}{dt} = v(t) = 2t$$

for $s(t)$ to obtain

$$s(t) = 2 \cdot \frac{t^2}{2} + C_2 = t^2 + C_2.$$

The initial condition $s(0) = 0$ determines

$$0 = (0)^2 + C_2 = C_2,$$

so $s(t) = t^2$. Therefore, after 10 seconds, the motorcycle has traveled

$$s(10) = (10)^2 = \boxed{100 \text{ m}}.$$

The Integral

5.1 Area

Concepts and Vocabulary

1. Partition the interval $[a, b]$ into n subintervals of length Δx . Then approximate the actual area under the graph of $f(x)$ on each subinterval using a rectangle of height $f(t_i)$, where t_i is some point in the n^{th} subinterval. The area under the graph of $f(x)$ is approximately the sum of the areas of the approximating rectangles: $A \approx \sum_{i=1}^n f(t_i) \Delta x$.
2. False. The length of each subinterval is $\frac{b-a}{n}$.
3. If the closed interval $[-2, 4]$ is partitioned into 12 subintervals, each of the same length, then the length of each subinterval is $\frac{4 - (-2)}{12} = \boxed{\frac{1}{2}}$.
4. True.

Skill Building

5. Let $f(x) = \frac{1}{2}x + 3$.
 - (a) The four rectangles whose heights are determined by the value of the function at the left endpoint of each subinterval are shown in the figure below. With $\Delta x = \frac{1}{2}$, the sum of the areas of the four rectangles is

$$\begin{aligned} \Delta x \left[f(2) + f\left(\frac{5}{2}\right) + f(3) + f\left(\frac{7}{2}\right) \right] \\ &= \left(\frac{1}{2}\right) \left[\left(\frac{1}{2}(2) + 3\right) + \left(\frac{1}{2}\left(\frac{5}{2}\right) + 3\right) + \left(\frac{1}{2}(3) + 3\right) + \left(\frac{1}{2}\left(\frac{7}{2}\right) + 3\right) \right] \\ &= \left(\frac{1}{2}\right) \left(4 + \frac{17}{4} + \frac{9}{2} + \frac{19}{4}\right) = \left(\frac{1}{2}\right) \left(\frac{35}{2}\right) = \boxed{\frac{35}{4}}. \end{aligned}$$

- (b) The four rectangles whose heights are determined by the value of the function at the right endpoint of each subinterval are shown in the figure below. With $\Delta x = \frac{1}{2}$, so the sum of the areas of the four rectangles is

$$\begin{aligned}
 \Delta x \left[f\left(\frac{5}{2}\right) + f(3) + f\left(\frac{7}{2}\right) + f(4) \right] \\
 &= \left(\frac{1}{2}\right) \left[\left(\frac{1}{2}\left(\frac{5}{2}\right) + 3\right) + \left(\frac{1}{2}(3) + 3\right) + \left(\frac{1}{2}\left(\frac{7}{2}\right) + 3\right) + \left(\frac{1}{2}(4) + 3\right) \right] \\
 &= \left(\frac{1}{2}\right) \left(\frac{17}{4} + \frac{9}{2} + \frac{19}{4} + 5\right) = \left(\frac{1}{2}\right) \left(\frac{37}{2}\right) = \boxed{\frac{37}{4}}.
 \end{aligned}$$

- (c) We have $\frac{35}{4} < 9 < \frac{37}{4}$, as expected. The function $f(x) = \frac{1}{2}x + 3$ is increasing, so the approximation using left endpoints in part (a) is an underestimate, and the approximation using right endpoints in part (b) is an overestimate. Moreover, as noted in Example 1, the error in approximating A is 1 square unit with $n = 1$ and 0.5 square units with $n = 2$. With $n = 4$, the error in approximating A is only 0.25 square units.

6. Let $f(x) = 6 - 2x$.

- (a) The four rectangles whose heights are determined by the value of the function at the right endpoint of each subinterval are shown in the figure below. With $\Delta x = \frac{1}{2}$, the

sum of the areas of the four rectangles is

$$\begin{aligned}
 \Delta x \left[f\left(\frac{3}{2}\right) + f(2) + f\left(\frac{5}{2}\right) + f(3) \right] \\
 &= \left(\frac{1}{2}\right) \left[\left(6 - 2\left(\frac{3}{2}\right)\right) + (6 - 2(2)) + \left(6 - 2\left(\frac{5}{2}\right)\right) + (6 - 2(3)) \right] \\
 &= \left(\frac{1}{2}\right) (3 + 2 + 1 + 0) = \left(\frac{1}{2}\right) (6) = \boxed{3}.
 \end{aligned}$$

- (b) The four rectangles whose heights are determined by the value of the function at the left endpoint of each subinterval are shown in the figure below. With $\Delta x = \frac{1}{2}$, so the sum of the areas of the four rectangles is

$$\begin{aligned}
 \Delta x \left[f(1) + f\left(\frac{3}{2}\right) + f(2) + f\left(\frac{5}{2}\right) \right] \\
 &= \left(\frac{1}{2}\right) \left[(6 - 2(1)) + \left(6 - 2\left(\frac{3}{2}\right)\right) + (6 - 2(2)) + \left(6 - 2\left(\frac{5}{2}\right)\right) \right] \\
 &= \left(\frac{1}{2}\right) (4 + 3 + 2 + 1) = \left(\frac{1}{2}\right) (10) = \boxed{5}.
 \end{aligned}$$

- (c) We have $3 < 4 < 5$, as expected. The function $f(x) = 6 - 2x$ is decreasing, so

the approximation using right endpoints in part (a) is an underestimate, and the approximation using left endpoints in part (b) is an overestimate.

7. From the figure, we see that $\Delta x = 1$ and that the subintervals are $[1, 2]$ and $[2, 3]$.

- (a) By constructing rectangles using the left endpoint of each subinterval, the area under the graph of f is approximately

$$\Delta x [f(1) + f(2)] = 1(1 + 2) = 3.$$

- (b) By constructing rectangles using the right endpoint of each subinterval, the area under the graph of f is approximately

$$\Delta x [f(2) + f(3)] = 1(2 + 4) = 6.$$

8. From the figure, we see that $\Delta x = 1$ and that the subintervals are $[1, 2]$, $[2, 3]$ and $[3, 4]$.

- (a) By constructing rectangles using the left endpoint of each subinterval, the area under the graph of f is approximately

$$\Delta x [f(1) + f(2) + f(3)] = 1 \left(\frac{7}{2} + \frac{5}{2} + 2 \right) = 8.$$

- (b) By constructing rectangles using the right endpoint of each subinterval, the area under the graph of f is approximately

$$\Delta x [f(2) + f(3) + f(4)] = 1 \left(\frac{5}{2} + 2 + \frac{1}{2} \right) = 5.$$

9. The length of the interval $[1, 4]$ is $4 - 1 = 3$, so with $n = 3$ subintervals, the length of each subinterval is

$$\Delta x = \frac{4 - 1}{3} = 1.$$

The coordinates of the endpoints of the subintervals are $x_0 = 1$, $x_1 = 1 + 1 = 2$, $x_2 = 2 + 1 = 3$, and $x_3 = 3 + 1 = 4$; the subintervals are

$$\boxed{[1, 2], [2, 3], \text{ and } [3, 4]}.$$

10. The length of the interval $[0, 9]$ is $9 - 0 = 9$, so with $n = 9$ subintervals, the length of each subinterval is

$$\Delta x = \frac{9 - 0}{9} = 1.$$

The coordinates of the endpoints of the subintervals are $x_0 = 0$, $x_1 = 0 + 1 = 1$, $x_2 = 1 + 1 = 2$, $x_3 = 2 + 1 = 3$, $x_4 = 3 + 1 = 4$, $x_5 = 4 + 1 = 5$, $x_6 = 5 + 1 = 6$, $x_7 = 6 + 1 = 7$, $x_8 = 7 + 1 = 8$, and $x_9 = 8 + 1 = 9$; the subintervals are

$$\boxed{[0, 1], [1, 2], [2, 3], [3, 4], [4, 5], [5, 6], [6, 7], [7, 8], \text{ and } [8, 9]}.$$

11. The length of the interval $[-1, 4]$ is $4 - (-1) = 5$, so with $n = 10$ subintervals, the length of each subinterval is

$$\Delta x = \frac{4 - (-1)}{10} = \frac{5}{10} = \frac{1}{2}.$$

The coordinates of the endpoints of the subintervals are

$$\left\{ -1, -\frac{1}{2}, 0, \frac{1}{2}, 1, \frac{3}{2}, 2, \frac{5}{2}, 3, \frac{7}{2}, 4 \right\};$$

the subintervals are

$$\left[-1, -\frac{1}{2} \right], \left[-\frac{1}{2}, 0 \right], \left[0, \frac{1}{2} \right], \left[\frac{1}{2}, 1 \right], \left[1, \frac{3}{2} \right], \left[\frac{3}{2}, 2 \right], \left[2, \frac{5}{2} \right], \left[\frac{5}{2}, 3 \right], \left[3, \frac{7}{2} \right], \text{ and } \left[\frac{7}{2}, 4 \right].$$

12. The length of the subinterval $[-4, 4]$ is $4 - (-4) = 8$, so with $n = 16$ subintervals, the length of each subinterval is

$$\Delta x = \frac{4 - (-4)}{16} = \frac{8}{16} = \frac{1}{2}.$$

The coordinates of the endpoints of the subintervals are

$$\left\{ -4, -\frac{7}{2}, -3, -\frac{5}{2}, -2, -\frac{3}{2}, -1, -\frac{1}{2}, 0, \frac{1}{2}, 1, \frac{3}{2}, 2, \frac{5}{2}, 3, \frac{7}{2}, 4 \right\};$$

the subintervals are

$$\left[-4, -\frac{7}{2} \right], \left[-\frac{7}{2}, -3 \right], \left[-3, -\frac{5}{2} \right], \left[-\frac{5}{2}, -2 \right], \left[-2, -\frac{3}{2} \right], \left[-\frac{3}{2}, -1 \right], \left[-1, -\frac{1}{2} \right], \left[-\frac{1}{2}, 0 \right], \\ \left[0, \frac{1}{2} \right], \left[\frac{1}{2}, 1 \right], \left[1, \frac{3}{2} \right], \left[\frac{3}{2}, 2 \right], \left[2, \frac{5}{2} \right], \left[\frac{5}{2}, 3 \right], \left[3, \frac{7}{2} \right], \text{ and } \left[\frac{7}{2}, 4 \right].$$

13. From the figure, we see that $\Delta x = 2$ and that the subintervals are $[0, 2]$, $[2, 4]$, $[4, 6]$ and $[6, 8]$.

- (a) On the subinterval $[0, 2]$, the absolute minimum value of the function is $f(0) = 1$; on the subinterval $[2, 4]$, the absolute minimum value of the function is $f(4) = 3$; on the subinterval $[4, 6]$, the absolute minimum value of the function is $f(4) = 3$; and on the subinterval $[6, 8]$, the absolute minimum value of the function is $f(8) = 0$. Thus,

$$s_4 = \Delta x [f(0) + f(4) + f(4) + f(8)] = 2(1 + 3 + 3 + 0) = 14.$$

- (b) On the subinterval $[0, 2]$, the absolute maximum value of the function is $f(2) = 5$; on the subinterval $[2, 4]$, the absolute maximum value of the function is $f(2) = 5$; on the subinterval $[4, 6]$, the absolute maximum value of the function is $f(6) = 7$; and on the subinterval $[6, 8]$, the absolute maximum value of the function is $f(6) = 7$. Thus,

$$S_4 = \Delta x [f(2) + f(2) + f(6) + f(6)] = 2(5 + 5 + 7 + 7) = 48.$$

14. From the figure, we see that $\Delta x = 2$ and that the subintervals are $[0, 2]$, $[2, 4]$, $[4, 6]$ and $[6, 8]$.

- (a) On the subinterval $[0, 2]$, the absolute minimum value of the function is $f(2) = 2$; on the subinterval $[2, 4]$, the absolute minimum value of the function is $f(2) = 2$; on the subinterval $[4, 6]$, the absolute minimum value of the function is $f(6) = 2$; and on the subinterval $[6, 8]$, the absolute minimum value of the function is $f(8) = 0$. Thus,

$$s_4 = \Delta x [f(2) + f(2) + f(6) + f(8)] = 2(2 + 2 + 2 + 0) = 12.$$

- (b) On the subinterval $[0, 2]$, the absolute maximum value of the function is $f(0) = 6$; on the subinterval $[2, 4]$, the absolute maximum value of the function is $f(4) = 4$; on the subinterval $[4, 6]$, the absolute maximum value of the function is $f(4) = 4$; and on the subinterval $[6, 8]$, the absolute maximum value of the function is $f(6) = 2$. Thus,

$$S_4 = \Delta x [f(0) + f(4) + f(4) + f(6)] = 2(6 + 4 + 4 + 2) = 32.$$

15. Let $f(x) = x$, and consider the area under the graph of f from 0 to 3.

(a) The graph of f from 0 to 3 is shown below. The area below the graph is shaded.

(b) Partition the interval $[0, 3]$ into n subintervals

$$[x_0, x_1], [x_1, x_2], \dots, [x_{i-1}, x_i], \dots, [x_{n-1}, x_n]$$

where

$$0 = x_0 < x_1 < x_2 < \dots < x_i < \dots < x_{n-1} < x_n = 3$$

and each subinterval is of length

$$\Delta x = \frac{3 - 0}{n} = \frac{3}{n}.$$

The coordinates of the endpoints of each subinterval are

$$x_0 = 0, x_1 = \frac{3}{n}, x_2 = 2\left(\frac{3}{n}\right), \dots, x_{i-1} = (i-1)\left(\frac{3}{n}\right),$$

$$x_i = i\left(\frac{3}{n}\right), \dots, x_n = n\left(\frac{3}{n}\right) = 3.$$

(c) To approximate the area under the graph of f using lower sums, we must find the absolute minimum value of f on each subinterval. Because f is an increasing function, the absolute minimum on each subinterval occurs at the left endpoint of the subinterval. Thus,

$$c_i = x_{i-1} = (i-1)\left(\frac{3}{n}\right),$$

and

$$s_n = \sum_{i=1}^n f(c_i) \Delta x = \sum_{i=1}^n c_i \Delta x = \sum_{i=1}^n (i-1) \left(\frac{3}{n}\right) \cdot \frac{3}{n} = \sum_{i=1}^n (i-1) \left(\frac{3}{n}\right)^2.$$

(d) To approximate the area under the graph of f using upper sums, we must find the absolute maximum value of f on each subinterval. Because f is an increasing function, the absolute maximum on each subinterval occurs at the right endpoint of the subinterval. Thus,

$$C_i = x_i = i\left(\frac{3}{n}\right),$$

and

$$S_n = \sum_{i=1}^n f(C_i) \Delta x = \sum_{i=1}^n C_i \Delta x = \sum_{i=1}^n i \left(\frac{3}{n} \right) \cdot \frac{3}{n} = \sum_{i=1}^n i \left(\frac{3}{n} \right)^2.$$

(e) Using summation properties and the result from part (c),

$$\begin{aligned} s_n &= \sum_{i=1}^n (i-1) \left(\frac{3}{n} \right)^2 = \frac{9}{n^2} \sum_{i=1}^n (i-1) = \frac{9}{n^2} \left(\sum_{i=1}^n i - \sum_{i=1}^n 1 \right) \\ &= \frac{9}{n^2} \left(\frac{n(n+1)}{2} - n \right) = 9 \left(\frac{n+1}{2n} - \frac{1}{n} \right) \\ &= \frac{9}{2} \left(1 - \frac{1}{n} \right); \end{aligned}$$

it follows that

$$\lim_{n \rightarrow \infty} s_n = \lim_{n \rightarrow \infty} \frac{9}{2} \left(1 - \frac{1}{n} \right) = \frac{9}{2} (1 - 0) = \frac{9}{2}.$$

Using summation properties and the result from part (d),

$$\begin{aligned} S_n &= \sum_{i=1}^n i \left(\frac{3}{n} \right)^2 = \frac{9}{n^2} \sum_{i=1}^n i \\ &= \frac{9}{n^2} \cdot \frac{n(n+1)}{2} = \frac{9}{2} \cdot \frac{n+1}{n} \\ &= \frac{9}{2} \left(1 + \frac{1}{n} \right); \end{aligned}$$

it follows that

$$\lim_{n \rightarrow \infty} S_n = \lim_{n \rightarrow \infty} \frac{9}{2} \left(1 + \frac{1}{n} \right) = \frac{9}{2} (1 + 0) = \frac{9}{2}.$$

Thus,

$$\lim_{n \rightarrow \infty} s_n = \lim_{n \rightarrow \infty} S_n = \frac{9}{2}.$$

16. Let $f(x) = 4x$, and consider the area under the graph of f from 0 to 5.

(a) The graph of f from 0 to 5 is shown below. The area below the graph is shaded.

- (b) Partition the interval $[0, 5]$ into n subintervals

$$[x_0, x_1], [x_1, x_2], \dots, [x_{i-1}, x_i], \dots, [x_{n-1}, x_n]$$

where

$$0 = x_0 < x_1 < x_2 < \dots < x_i < \dots < x_{n-1} < x_n = 5$$

and each subinterval is of length

$$\Delta x = \frac{5 - 0}{n} = \frac{5}{n}.$$

The coordinates of the endpoints of each subinterval are

$$\begin{aligned} x_0 = 0, x_1 = \frac{5}{n}, x_2 = 2\left(\frac{5}{n}\right), \dots, x_{i-1} = (i-1)\left(\frac{5}{n}\right), \\ x_i = i\left(\frac{5}{n}\right), \dots, x_n = n\left(\frac{5}{n}\right) = 5. \end{aligned}$$

- (c) To approximate the area under the graph of f using lower sums, we must find the absolute minimum value of f on each subinterval. Because f is an increasing function, the absolute minimum on each subinterval occurs at the left endpoint of the subinterval. Thus,

$$c_i = x_{i-1} = (i-1)\left(\frac{5}{n}\right),$$

and

$$s_n = \sum_{i=1}^n f(c_i) \Delta x = \sum_{i=1}^n 4c_i \Delta x = \sum_{i=1}^n 4(i-1)\left(\frac{5}{n}\right) \cdot \frac{5}{n} = \sum_{i=1}^n (i-1) \frac{100}{n^2}.$$

- (d) To approximate the area under the graph of f using upper sums, we must find the absolute maximum value of f on each subinterval. Because f is an increasing function, the absolute maximum on each subinterval occurs at the right endpoint of the subinterval. Thus,

$$C_i = x_i = i\left(\frac{5}{n}\right),$$

and

$$S_n = \sum_{i=1}^n f(C_i) \Delta x = \sum_{i=1}^n 4C_i \Delta x = \sum_{i=1}^n 4i\left(\frac{5}{n}\right) \cdot \frac{5}{n} = \sum_{i=1}^n i \frac{100}{n^2}.$$

- (e) Using summation properties and the result from part (c),

$$\begin{aligned} s_n &= \sum_{i=1}^n (i-1) \frac{100}{n^2} = \frac{100}{n^2} \sum_{i=1}^n (i-1) = \frac{100}{n^2} \left(\sum_{i=1}^n i - \sum_{i=1}^n 1 \right) \\ &= \frac{100}{n^2} \left(\frac{n(n+1)}{2} - n \right) = 100 \left(\frac{n+1}{2n} - \frac{1}{n} \right) \\ &= 50 \left(1 - \frac{1}{n} \right); \end{aligned}$$

it follows that

$$\lim_{n \rightarrow \infty} s_n = \lim_{n \rightarrow \infty} 50 \left(1 - \frac{1}{n} \right) = 50(1 - 0) = 50.$$

Using summation properties and the result from part (d),

$$\begin{aligned} S_n &= \sum_{i=1}^n i \frac{100}{n^2} = \frac{100}{n^2} \sum_{i=1}^n i \\ &= \frac{100}{n^2} \cdot \frac{n(n+1)}{2} = 50 \cdot \frac{n+1}{n} \\ &= 50 \left(1 + \frac{1}{n} \right); \end{aligned}$$

it follows that

$$\lim_{n \rightarrow \infty} S_n = \lim_{n \rightarrow \infty} 50 \left(1 + \frac{1}{n} \right) = 50(1 + 0) = 50.$$

Thus,

$$\lim_{n \rightarrow \infty} s_n = \lim_{n \rightarrow \infty} S_n = 50.$$

17. Let $f(x) = -x + 10$. Because f is decreasing on the interval $[0, 8]$, the absolute minimum on any subinterval will occur at the right endpoint of the subinterval, and the absolute maximum on any subinterval will occur at the left endpoint of the subinterval.

(a) With $n = 4$,

$$\Delta x = \frac{8-0}{4} = 2, \quad c_i = 0 + i\Delta x = 2i,$$

and

$$\begin{aligned} s_4 &= \sum_{i=1}^4 f(c_i) \Delta x \\ &= (2) [f(c_1) + f(c_2) + f(c_3) + f(c_4)] \\ &= (2) [f(2) + f(4) + f(6) + f(8)] \\ &= (2) (8 + 6 + 4 + 2) \\ &= \boxed{40}. \end{aligned}$$

With $n = 8$, $\Delta x = \frac{8-0}{8} = 1$, $c_i = 0 + i\Delta x = i$, and

$$\begin{aligned} s_8 &= \sum_{i=1}^8 f(c_i) \Delta x \\ &= (1) [f(c_1) + \cdots + f(c_8)] \\ &= (1) [f(1) + f(2) + \cdots + f(8)] \\ &= (1) (9 + 8 + 7 + 6 + 5 + 4 + 3 + 2) \\ &= \boxed{44}. \end{aligned}$$

(b) With $n = 4$,

$$\Delta x = \frac{8-0}{4} = 2, \quad C_i = 0 + (i-1)\Delta x = 2(i-1),$$

and

$$\begin{aligned} S_4 &= \sum_{i=1}^4 f(C_i) \Delta x \\ &= (2) [f(C_1) + f(C_2) + f(C_3) + f(C_4)] \\ &= (2) [f(0) + f(2) + f(4) + f(6)] \\ &= (2) (10 + 8 + 6 + 4) \\ &= \boxed{56}. \end{aligned}$$

With $n = 8$, $\Delta x = \frac{8-0}{8} = 1$, $C_i = 0 + (i-1)\Delta x = i-1$, and

$$\begin{aligned}
 S_8 &= \sum_{i=1}^8 f(C_i) \Delta x \\
 &= (1)[f(C_1) + \cdots + f(C_8)] \\
 &= (1)[f(0) + f(1) + \cdots + f(6) + f(7)] \\
 &= (1)(10 + 9 + 8 + 7 + 6 + 5 + 4 + 3) \\
 &= \boxed{52}.
 \end{aligned}$$

18. Let $f(x) = 2x + 5$. Because f is increasing on the interval $[2, 6]$, the absolute minimum on any subinterval will occur at the left endpoint of the subinterval, and the absolute maximum on any subinterval will occur at the right endpoint of the subinterval.

(a) With $n = 4$, $\Delta x = \frac{6-2}{4} = 1$,

$$c_i = 2 + (i-1)\Delta x = 2 + (i-1)(1) = 1 + i,$$

and

$$\begin{aligned}
 s_4 &= \sum_{i=1}^4 f(c_i) \Delta x \\
 &= (1)[f(c_1) + f(c_2) + f(c_3) + f(c_4)] \\
 &= (1)[f(2) + f(3) + f(4) + f(5)] \\
 &= (1)(9 + 11 + 13 + 15) \\
 &= \boxed{48}.
 \end{aligned}$$

With $n = 8$,

$$\Delta x = \frac{6-2}{8} = \frac{1}{2}, \quad c_i = 2 + (i-1)\Delta x = 2 + (i-1)\left(\frac{1}{2}\right) = \frac{3}{2} + \frac{1}{2}i,$$

and

$$\begin{aligned}
 s_8 &= \sum_{i=1}^8 f(c_i) \Delta x \\
 &= \left(\frac{1}{2}\right)[f(c_1) + \cdots + f(c_8)] \\
 &= \left(\frac{1}{2}\right)\left[f(2) + f\left(\frac{5}{2}\right) + \cdots + f(5) + f\left(\frac{11}{2}\right)\right] \\
 &= \left(\frac{1}{2}\right)(9 + 10 + 11 + 12 + 13 + 14 + 15 + 16) \\
 &= \boxed{50}.
 \end{aligned}$$

(b) With $n = 4$, $\Delta x = \frac{6-2}{4} = 1$, $C_i = 2 + i\Delta x = 2 + i$, and

$$\begin{aligned}
 S_4 &= \sum_{i=1}^4 f(C_i) \Delta x \\
 &= (1)[f(C_1) + f(C_2) + f(C_3) + f(C_4)] \\
 &= (1)[f(3) + f(4) + f(5) + f(6)] \\
 &= (1)(11 + 13 + 15 + 17) \\
 &= \boxed{56}.
 \end{aligned}$$

With $n = 8$,

$$\Delta x = \frac{6-2}{8} = \frac{1}{2}, \quad C_i = 2 + i\Delta x = 2 + \frac{1}{2}i,$$

and

$$\begin{aligned} S_8 &= \sum_{i=1}^8 f(C_i) \Delta x \\ &= \left(\frac{1}{2}\right) [f(C_1) + \cdots + f(C_8)] \\ &= \left(\frac{1}{2}\right) \left[f\left(\frac{5}{2}\right) + f(3) + \cdots + f\left(\frac{11}{2}\right) + f(6) \right] \\ &= \left(\frac{1}{2}\right) (10 + 11 + 12 + 13 + 14 + 15 + 16 + 17) \\ &= \boxed{54}. \end{aligned}$$

19. Let $f(x) = 16 - x^2$. Because f is decreasing on the interval $[0, 4]$, the absolute minimum on any subinterval will occur at the right endpoint of the subinterval, and the absolute maximum on any subinterval will occur at the left endpoint of the subinterval.

(a) With $n = 4$, $\Delta x = \frac{4-0}{4} = 1$, $c_i = 0 + i\Delta x = i$, and

$$\begin{aligned} s_4 &= \sum_{i=1}^4 f(c_i) \Delta x \\ &= (1) [f(c_1) + f(c_2) + f(c_3) + f(c_4)] \\ &= (1) [f(1) + f(2) + f(3) + f(4)] \\ &= (1) (15 + 12 + 7 + 0) \\ &= \boxed{34}. \end{aligned}$$

With $n = 8$,

$$\Delta x = \frac{4-0}{8} = \frac{1}{2}, \quad c_i = 0 + i\Delta x = \frac{1}{2}i,$$

and

$$\begin{aligned} s_8 &= \sum_{i=1}^8 f(c_i) \Delta x \\ &= \left(\frac{1}{2}\right) [f(c_1) + \cdots + f(c_8)] \\ &= \left(\frac{1}{2}\right) \left(f\left(\frac{1}{2}\right) + f(1) + \cdots + f\left(\frac{7}{2}\right) + f(4) \right) \\ &= \left(\frac{1}{2}\right) \left(\frac{63}{4} + 15 + \frac{55}{4} + 12 + \frac{39}{4} + 7 + \frac{15}{4} + 0 \right) \\ &= \boxed{\frac{77}{2}}. \end{aligned}$$

(b) With $n = 4$, $\Delta x = \frac{4-0}{4} = 1$, $C_i = 0 + (i-1)\Delta x = i-1$, and

$$\begin{aligned}
 S_4 &= \sum_{i=1}^4 f(C_i) \Delta x \\
 &= (1)[f(C_1) + f(C_2) + f(C_3) + f(C_4)] \\
 &= (1)[f(0) + f(1) + f(2) + f(3)] \\
 &= (1)(16 + 15 + 12 + 7) \\
 &= \boxed{50}.
 \end{aligned}$$

With $n = 8$,

$$\Delta x = \frac{4-0}{8} = \frac{1}{2}, \quad C_i = 0 + (i-1)\Delta x = \frac{i-1}{2},$$

and

$$\begin{aligned}
 S_8 &= \sum_{i=1}^8 f(C_i) \Delta x \\
 &= \left(\frac{1}{2}\right)[f(C_1) + \cdots + f(C_8)] \\
 &= \left(\frac{1}{2}\right)\left[f(0) + f\left(\frac{1}{2}\right) + \cdots + f(3) + f\left(\frac{7}{2}\right)\right] \\
 &= \left(\frac{1}{2}\right)\left(16 + \frac{63}{4} + 15 + \frac{55}{4} + 12 + \frac{39}{4} + 7 + \frac{15}{4}\right) \\
 &= \boxed{\frac{93}{2}}.
 \end{aligned}$$

20. Let $f(x) = x^3$. Because f is increasing on the interval $[0, 8]$, the absolute minimum on any subinterval will occur at the left endpoint of the subinterval, and the absolute maximum on any subinterval will occur at the right endpoint of the subinterval.

(a) With $n = 4$, $\Delta x = \frac{8-0}{4} = 2$, $c_i = 0 + (i-1)\Delta x = 2(i-1)$, and

$$\begin{aligned}
 s_4 &= \sum_{i=1}^4 f(c_i) \Delta x \\
 &= (2)[f(c_1) + f(c_2) + f(c_3) + f(c_4)] \\
 &= (2)[f(0) + f(2) + f(4) + f(6)] \\
 &= (2)(0 + 8 + 64 + 216) \\
 &= \boxed{576}.
 \end{aligned}$$

With $n = 8$, $\Delta x = \frac{8-0}{8} = 1$, $c_i = 0 + (i-1)\Delta x = i-1$, and

$$\begin{aligned}
 s_8 &= \sum_{i=1}^8 f(c_i) \Delta x \\
 &= (1)[f(c_1) + \cdots + f(c_8)] \\
 &= (1)[f(0) + f(1) + \cdots + f(6) + f(7)] \\
 &= (1)(0 + 1 + 8 + 27 + 64 + 125 + 216 + 343) \\
 &= \boxed{784}.
 \end{aligned}$$

(b) With $n = 4$, $\Delta x = \frac{8-0}{4} = 2$, $C_i = 0 + i\Delta x = 2i$, and

$$\begin{aligned}
 S_4 &= \sum_{i=1}^4 f(C_i) \Delta x \\
 &= (2) [f(C_1) + f(C_2) + f(C_3) + f(C_4)] \\
 &= (2) [f(2) + f(4) + f(6) + f(8)] \\
 &= (2) (8 + 64 + 216 + 512) \\
 &= \boxed{1600}.
 \end{aligned}$$

With $n = 8$, $\Delta x = \frac{8-0}{8} = 1$, $C_i = 0 + i\Delta x = i$, and

$$\begin{aligned}
 S_8 &= \sum_{i=1}^8 f(C_i) \Delta x \\
 &= (1) [f(C_1) + \cdots + f(C_8)] \\
 &= (1) [f(1) + f(2) + \cdots + f(7) + f(8)] \\
 &= (1) (1 + 8 + 27 + 64 + 125 + 216 + 343 + 512) \\
 &= \boxed{1296}.
 \end{aligned}$$

21. Let $f(x) = \cos x$.

(a) With $n = 4$,

$$\Delta x = \frac{\pi/2 - (-\pi/2)}{4} = \frac{\pi}{4}.$$

Because f is increasing on $[-\frac{\pi}{2}, 0]$, and decreasing on $[0, \frac{\pi}{2}]$, the absolute minimum on the subintervals determined by the partition points $\{-\frac{\pi}{2}, -\frac{\pi}{4}, 0, \frac{\pi}{4}, \frac{\pi}{2}\}$ occurs at the points $c_1 = -\frac{\pi}{2}$, $c_2 = -\frac{\pi}{4}$, $c_3 = \frac{\pi}{4}$, and $c_4 = \frac{\pi}{2}$. Thus,

$$\begin{aligned}
 s_4 &= \sum_{i=1}^4 f(c_i) \Delta x \\
 &= \left(\frac{\pi}{4}\right) [f(c_1) + f(c_2) + f(c_3) + f(c_4)] \\
 &= \left(\frac{\pi}{4}\right) \left[f\left(-\frac{\pi}{2}\right) + f\left(-\frac{\pi}{4}\right) + f\left(\frac{\pi}{4}\right) + f\left(\frac{\pi}{2}\right)\right] \\
 &= \left(\frac{\pi}{4}\right) \left(0 + \frac{\sqrt{2}}{2} + \frac{\sqrt{2}}{2} + 0\right) \\
 &= \boxed{\frac{\sqrt{2}}{4}\pi \approx 1.111}.
 \end{aligned}$$

With $n = 8$,

$$\Delta x = \frac{\pi/2 - (-\pi/2)}{8} = \frac{\pi}{8}.$$

The absolute minimum on the subintervals determined by the partition points

$$\left\{-\frac{\pi}{2}, -\frac{3\pi}{8}, -\frac{\pi}{4}, -\frac{\pi}{8}, 0, \frac{\pi}{8}, \frac{\pi}{4}, \frac{3\pi}{8}, \frac{\pi}{2}\right\}$$

occurs at the points $c_1 = -\frac{\pi}{2}$, $c_2 = -\frac{3\pi}{8}$, $c_3 = -\frac{\pi}{4}$, $c_4 = -\frac{\pi}{8}$, $c_5 = \frac{\pi}{8}$, $c_6 = \frac{\pi}{4}$, $c_7 = \frac{3\pi}{8}$, and $c_8 = \frac{\pi}{2}$. Thus,

$$\begin{aligned}
 s_8 &= \sum_{i=1}^8 f(c_i) \Delta x \\
 &= \left(\frac{\pi}{8}\right) [f(c_1) + \cdots + f(c_8)] \\
 &= \left(\frac{\pi}{8}\right) \left[f\left(-\frac{\pi}{2}\right) + f\left(-\frac{3\pi}{8}\right) + f\left(-\frac{\pi}{4}\right) + f\left(-\frac{\pi}{8}\right) \right. \\
 &\quad \left. + f\left(\frac{\pi}{8}\right) + f\left(\frac{\pi}{4}\right) + f\left(\frac{3\pi}{8}\right) + f\left(\frac{\pi}{2}\right) \right] \\
 &= \left(\frac{\pi}{8}\right) \left(0 + \frac{\sqrt{2-\sqrt{2}}}{2} + \frac{\sqrt{2}}{2} + \frac{\sqrt{\sqrt{2}+2}}{2} + \frac{\sqrt{\sqrt{2}+2}}{2} + \frac{\sqrt{2}}{2} + \frac{\sqrt{2-\sqrt{2}}}{2} + 0 \right) \\
 &= \boxed{\frac{\sqrt{2-\sqrt{2}} + \sqrt{\sqrt{2}+2} + \sqrt{2}}{8} \pi \approx 1.582}.
 \end{aligned}$$

(b) With $n = 4$,

$$\Delta x = \frac{\pi/2 - (-\pi/2)}{4} = \frac{\pi}{4}.$$

Because f is increasing on $[-\frac{\pi}{2}, 0]$, and decreasing on $[0, \frac{\pi}{2}]$, the absolute maximum on the subintervals determined by the partition points $\{-\frac{\pi}{2}, -\frac{\pi}{4}, 0, \frac{\pi}{4}, \frac{\pi}{2}\}$ occurs at the points $C_1 = -\frac{\pi}{4}$, $C_2 = 0$, $C_3 = 0$, and $C_4 = \frac{\pi}{4}$. Thus,

$$\begin{aligned}
 S_4 &= \sum_{i=1}^4 f(C_i) \Delta x \\
 &= \left(\frac{\pi}{4}\right) [f(C_1) + f(C_2) + f(C_3) + f(C_4)] \\
 &= \left(\frac{\pi}{4}\right) \left[f\left(-\frac{\pi}{4}\right) + f(0) + f(0) + f\left(\frac{\pi}{4}\right) \right] \\
 &= \left(\frac{\pi}{4}\right) \left(\frac{\sqrt{2}}{2} + 1 + 1 + \frac{\sqrt{2}}{2} \right) \\
 &= \boxed{\frac{\sqrt{2}+2}{4} \pi \approx 2.682}.
 \end{aligned}$$

With $n = 8$,

$$\Delta x = \frac{\pi/2 - (-\pi/2)}{8} = \frac{\pi}{8}.$$

The absolute maximum on the subintervals determined by the partition points

$$\left\{ -\frac{\pi}{2}, -\frac{3\pi}{8}, -\frac{\pi}{4}, -\frac{\pi}{8}, 0, \frac{\pi}{8}, \frac{\pi}{4}, \frac{3\pi}{8}, \frac{\pi}{2} \right\}$$

occurs at the points $C_1 = -\frac{3\pi}{8}$, $C_2 = -\frac{\pi}{4}$, $C_3 = -\frac{\pi}{8}$, $C_4 = 0$, $C_5 = 0$, $C_6 = \frac{\pi}{8}$,

$C_7 = \frac{\pi}{4}$, and $C_8 = \frac{3\pi}{8}$. Thus,

$$\begin{aligned}
 S_8 &= \sum_{i=1}^8 f(C_i) \Delta x \\
 &= \left(\frac{\pi}{8}\right) [f(C_1) + \cdots + f(C_8)] \\
 &= \left(\frac{\pi}{8}\right) \left[f\left(-\frac{3\pi}{8}\right) + f\left(-\frac{\pi}{4}\right) + f\left(-\frac{\pi}{8}\right) + f(0) \right. \\
 &\quad \left. + f(0) + f\left(\frac{\pi}{8}\right) + f\left(\frac{\pi}{4}\right) + f\left(\frac{3\pi}{8}\right) \right] \\
 &= \left(\frac{\pi}{8}\right) \left(\frac{\sqrt{2-\sqrt{2}}}{2} + \frac{\sqrt{2}}{2} + \frac{\sqrt{\sqrt{2}+2}}{2} + 1 + 1 + \frac{\sqrt{\sqrt{2}+2}}{2} + \frac{\sqrt{2}}{2} + \frac{\sqrt{2-\sqrt{2}}}{2} \right) \\
 &= \boxed{\frac{\sqrt{2-\sqrt{2}} + \sqrt{\sqrt{2}+2} + \sqrt{2} + 2}{8} \pi \approx 2.367}.
 \end{aligned}$$

22. Let $f(x) = \sin x$.

(a) With $n = 4$,

$$\Delta x = \frac{\pi - 0}{4} = \frac{\pi}{4}.$$

Because f is increasing on $[0, \frac{\pi}{2}]$, and decreasing on $[\frac{\pi}{2}, \pi]$, the absolute minimum on the subintervals determined by the partition points $\{0, \frac{\pi}{4}, \frac{\pi}{2}, \frac{3\pi}{4}, \pi\}$ occurs at the points $c_1 = 0$, $c_2 = \frac{\pi}{4}$, $c_3 = \frac{3\pi}{4}$, and $c_4 = \pi$. Thus,

$$\begin{aligned}
 s_4 &= \sum_{i=1}^4 f(c_i) \Delta x \\
 &= \left(\frac{\pi}{4}\right) [f(c_1) + f(c_2) + f(c_3) + f(c_4)] \\
 &= \left(\frac{\pi}{4}\right) \left[f(0) + f\left(\frac{\pi}{4}\right) + f\left(\frac{3\pi}{4}\right) + f(\pi) \right] \\
 &= \left(\frac{\pi}{4}\right) \left(0 + \frac{\sqrt{2}}{2} + \frac{\sqrt{2}}{2} + 0 \right) \\
 &= \boxed{\frac{\sqrt{2}}{4} \pi \approx 1.111}.
 \end{aligned}$$

With $n = 8$,

$$\Delta x = \frac{\pi - 0}{8} = \frac{\pi}{8}.$$

The absolute minimum on the subintervals determined by the partition points

$$\left\{ 0, \frac{\pi}{8}, \frac{\pi}{4}, \frac{3\pi}{8}, \frac{\pi}{2}, \frac{5\pi}{8}, \frac{3\pi}{4}, \frac{7\pi}{8}, \pi \right\}$$

occurs at the points $c_1 = 0$, $c_2 = \frac{\pi}{8}$, $c_3 = \frac{\pi}{4}$, $c_4 = \frac{3\pi}{8}$, $c_5 = \frac{5\pi}{8}$, $c_6 = \frac{3\pi}{4}$, $c_7 = \frac{7\pi}{8}$, and

$c_8 = \frac{\pi}{2}$. Thus,

$$\begin{aligned}
 s_8 &= \sum_{i=1}^8 f(c_i) \Delta x \\
 &= \left(\frac{\pi}{8}\right) [f(c_1) + \cdots + f(c_8)] \\
 &= \left(\frac{\pi}{8}\right) \left[f(0) + f\left(\frac{\pi}{8}\right) + f\left(\frac{\pi}{4}\right) + f\left(\frac{3\pi}{8}\right) + \right. \\
 &\quad \left. f\left(\frac{5\pi}{8}\right) + f\left(\frac{3\pi}{4}\right) + f\left(\frac{7\pi}{8}\right) + f\left(\frac{\pi}{2}\right) \right] \\
 &= \left(\frac{\pi}{8}\right) \left(0 + \frac{\sqrt{2-\sqrt{2}}}{2} + \frac{\sqrt{2}}{2} + \frac{\sqrt{\sqrt{2}+2}}{2} + \frac{\sqrt{\sqrt{2}+2}}{2} + \frac{\sqrt{2}}{2} + \frac{\sqrt{2-\sqrt{2}}}{2} + 0 \right) \\
 &= \boxed{\frac{\sqrt{2-\sqrt{2}} + \sqrt{\sqrt{2}+2} + \sqrt{2}}{8} \pi \approx 1.582}.
 \end{aligned}$$

(b) With $n = 4$,

$$\Delta x = \frac{\pi - 0}{4} = \frac{\pi}{4}.$$

Because f is increasing on $[0, \frac{\pi}{2}]$, and decreasing on $[\frac{\pi}{2}, \pi]$, the absolute maximum on the subintervals determined by the partition points $\{0, \frac{\pi}{4}, \frac{\pi}{2}, \frac{3\pi}{4}, \pi\}$ occurs at the points $C_1 = \frac{\pi}{4}$, $C_2 = \frac{\pi}{2}$, $C_3 = \frac{\pi}{2}$, and $C_4 = \frac{3\pi}{4}$. Thus,

$$\begin{aligned}
 S_4 &= \sum_{i=1}^4 f(C_i) \Delta x \\
 &= \left(\frac{\pi}{4}\right) [f(C_1) + f(C_2) + f(C_3) + f(C_4)] \\
 &= \left(\frac{\pi}{4}\right) \left[f\left(\frac{\pi}{4}\right) + f\left(\frac{\pi}{2}\right) + f\left(\frac{\pi}{2}\right) + f\left(\frac{3\pi}{4}\right) \right] \\
 &= \left(\frac{\pi}{4}\right) \left(\frac{\sqrt{2}}{2} + 1 + 1 + \frac{\sqrt{2}}{2} \right) \\
 &= \boxed{\frac{\sqrt{2}+2}{4} \pi \approx 2.682}.
 \end{aligned}$$

With $n = 8$,

$$\Delta x = \frac{\pi - 0}{8} = \frac{\pi}{8}.$$

The absolute maximum on the subintervals determined by the partition points

$$\left\{ 0, \frac{\pi}{8}, \frac{\pi}{4}, \frac{3\pi}{8}, \frac{\pi}{2}, \frac{5\pi}{8}, \frac{3\pi}{4}, \frac{7\pi}{8}, \frac{\pi}{2} \right\}$$

occurs at the points $C_1 = \frac{\pi}{8}$, $C_2 = \frac{\pi}{4}$, $C_3 = \frac{3\pi}{8}$, $C_4 = \frac{\pi}{2}$, $C_5 = \frac{\pi}{2}$, $C_6 = \frac{5\pi}{8}$, $C_7 = \frac{3\pi}{4}$,

and $C_8 = \frac{7\pi}{8}$. Thus,

$$\begin{aligned}
 S_8 &= \sum_{i=1}^8 f(C_i) \Delta x \\
 &= \left(\frac{\pi}{8}\right) [f(C_1) + \cdots + f(C_8)] \\
 &= \left(\frac{\pi}{8}\right) \left[f\left(\frac{\pi}{8}\right) + f\left(\frac{\pi}{4}\right) + f\left(\frac{3\pi}{8}\right) + f\left(\frac{\pi}{2}\right) + \right. \\
 &\quad \left. f\left(\frac{\pi}{2}\right) + f\left(\frac{5\pi}{8}\right) + f\left(\frac{3\pi}{4}\right) + f\left(\frac{7\pi}{8}\right) \right] \\
 &= \left(\frac{\pi}{8}\right) \left(\frac{\sqrt{2}-\sqrt{2}}{2} + \frac{\sqrt{2}}{2} + \frac{\sqrt{\sqrt{2}+2}}{2} + 1 + 1 + \frac{\sqrt{\sqrt{2}+2}}{2} + \frac{\sqrt{2}}{2} + \frac{\sqrt{2}-\sqrt{2}}{2} \right) \\
 &= \boxed{\frac{\sqrt{2}-\sqrt{2}+\sqrt{\sqrt{2}+2}+\sqrt{2}+2}{8}\pi \approx 2.367}.
 \end{aligned}$$

23. Let $f(x) = 3x$. Because f is an increasing function on the interval $[0, 10]$, the absolute minimum on any subinterval occurs at the left endpoint of the subinterval. Thus,

$$c_i = (i-1) \left(\frac{10}{n} \right)$$

and

$$s_n = \sum_{i=1}^n f(c_i) \Delta x = \sum_{i=1}^n 3c_i \frac{10}{n} = \sum_{i=1}^n \left(3(i-1) \frac{10}{n} \right) \frac{10}{n} = \sum_{i=1}^n \left(\frac{300}{n^2} i - \frac{300}{n^2} \right).$$

Using summation properties,

$$s_n = \frac{300}{n^2} \sum_{i=1}^n i - \frac{300}{n^2} \sum_{i=1}^n 1 = \frac{300}{n^2} \frac{n(n+1)}{2} - \frac{300}{n^2} n = \frac{150(n+1)}{n} - \frac{300}{n} = 150 \left(1 + \frac{1}{n} \right) - \frac{300}{n}.$$

Therefore,

$$\begin{aligned}
 A &= \lim_{n \rightarrow \infty} s_n = \lim_{n \rightarrow \infty} \left[150 \left(1 + \frac{1}{n} \right) - \frac{300}{n} \right] = 150 \lim_{n \rightarrow \infty} \left(1 + \frac{1}{n} \right) - 300 \lim_{n \rightarrow \infty} \frac{1}{n} \\
 &= 150(1) - 300(0) = \boxed{150}.
 \end{aligned}$$

24. Let $f(x) = 16 - x^2$. Because f is a decreasing function on the interval $[0, 4]$, the absolute maximum on any subinterval occurs at the left endpoint of the subinterval. Thus,

$$C_i = (i-1) \left(\frac{4}{n} \right)$$

and

$$\begin{aligned}
 S_n &= \sum_{i=1}^n f(C_i) \Delta x = \sum_{i=1}^n (16 - C_i^2) \frac{4}{n} = \sum_{i=1}^n \left(16 - \left(\frac{4(i-1)}{n} \right)^2 \right) \frac{4}{n} \\
 &= \sum_{i=1}^n \left(16 - \left(16 \frac{i^2}{n^2} - 32 \frac{i}{n^2} + \frac{16}{n^2} \right) \right) \frac{4}{n} = \sum_{i=1}^n \left(\frac{64}{n} - \frac{64}{n^3} + \frac{128i}{n^3} - \frac{64i^2}{n^3} \right).
 \end{aligned}$$

Using summation properties,

$$\begin{aligned}
 S_n &= \left(\frac{64}{n} - \frac{64}{n^3} \right) \sum_{i=1}^n 1 + \frac{128}{n^3} \sum_{i=1}^n i - \frac{64}{n^3} \sum_{i=1}^n i^2 \\
 &= \left(\frac{64}{n} - \frac{64}{n^3} \right) n + \frac{128}{n^3} \frac{n(n+1)}{2} - \frac{64}{n^3} \frac{n(n+1)(2n+1)}{6} \\
 &= 64 - \frac{64}{n^2} + 64 \left(\frac{1}{n^2} + \frac{1}{n} \right) - \frac{32}{3} \left(1 + \frac{1}{n} \right) \left(2 + \frac{1}{n} \right).
 \end{aligned}$$

Therefore,

$$\begin{aligned}
 A &= \lim_{n \rightarrow \infty} S_n = \lim_{n \rightarrow \infty} \left[64 - \frac{64}{n^2} + 64 \left(\frac{1}{n^2} + \frac{1}{n} \right) - \frac{32}{3} \left(1 + \frac{1}{n} \right) \left(2 + \frac{1}{n} \right) \right] \\
 &= 64 - 64 \lim_{n \rightarrow \infty} \frac{1}{n^2} + 64 \lim_{n \rightarrow \infty} \left(\frac{1}{n^2} + \frac{1}{n} \right) - \frac{32}{3} \lim_{n \rightarrow \infty} \left(1 + \frac{1}{n} \right) \left(2 + \frac{1}{n} \right) \\
 &= 64 - 64(0) + 64(0) - \frac{32}{3}(2) = \boxed{\frac{128}{3}}.
 \end{aligned}$$

25. Let $f(x) = 2x + 1$, and consider the area under the graph of f from $a = 0$ to $b = 4$. Partition the interval $[0, 4]$ into n subintervals

$$[x_0, x_1], [x_1, x_2], \dots, [x_{i-1}, x_i], \dots, [x_{n-1}, x_n]$$

where

$$0 = x_0 < x_1 < x_2 < \dots < x_i < \dots < x_{n-1} < x_n = 4$$

and each subinterval is of length

$$\Delta x = \frac{4 - 0}{n} = \frac{4}{n}.$$

The coordinates of the endpoints of each subinterval are

$$\begin{aligned}
 x_0 &= 0, x_1 = \frac{4}{n}, x_2 = 2 \left(\frac{4}{n} \right), \dots, x_{i-1} = (i-1) \left(\frac{4}{n} \right), \\
 x_i &= i \left(\frac{4}{n} \right), \dots, x_n = n \left(\frac{4}{n} \right) = 4.
 \end{aligned}$$

- (a) To approximate the area under the graph of f using lower sums, we must find the absolute minimum value of f on each subinterval. Because f is an increasing function, the absolute minimum on each subinterval occurs at the left endpoint of the subinterval. Thus,

$$c_i = x_{i-1} = (i-1) \left(\frac{4}{n} \right),$$

and

$$s_n = \sum_{i=1}^n f(c_i) \Delta x = \sum_{i=1}^n \left(2(i-1) \left(\frac{4}{n} \right) + 1 \right) \frac{4}{n} = \sum_{i=1}^n \left(\frac{32i}{n^2} - \frac{32}{n^2} + \frac{4}{n} \right).$$

Using summation properties,

$$\begin{aligned}
 s_n &= \frac{32}{n^2} \sum_{i=1}^n i - \frac{32}{n^2} \sum_{i=1}^n 1 + \frac{4}{n} \sum_{i=1}^n 1 \\
 &= \frac{32}{n^2} \frac{n(n+1)}{2} - \frac{32}{n^2} (n) + \frac{4}{n} (n) = 16 \left(1 + \frac{1}{n} \right) - \frac{32}{n} + 4.
 \end{aligned}$$

Therefore

$$\begin{aligned} A &= \lim_{n \rightarrow \infty} s_n = \lim_{n \rightarrow \infty} \left[16 \left(1 + \frac{1}{n} \right) - \frac{32}{n} + 4 \right] \\ &= 16 \lim_{n \rightarrow \infty} \left(1 + \frac{1}{n} \right) - 32 \lim_{n \rightarrow \infty} \frac{1}{n} + 4 = 16(1) - 32(0) + 4 = \boxed{20}. \end{aligned}$$

- (b) To approximate the area under the graph of f using upper sums, we must find the absolute maximum value of f on each subinterval. Because f is an increasing function, the absolute maximum on each subinterval occurs at the right endpoint of the subinterval. Thus,

$$C_i = x_i = i \left(\frac{4}{n} \right),$$

and

$$S_n = \sum_{i=1}^n f(C_i) \Delta x = \sum_{i=1}^n \left(2i \left(\frac{4}{n} \right) + 1 \right) \frac{4}{n} = \sum_{i=1}^n \left(\frac{32i}{n^2} + \frac{4}{n} \right).$$

Using summation properties,

$$S_n = \frac{32}{n^2} \sum_{i=1}^n i + \frac{4}{n} \sum_{i=1}^n 1 = \frac{32}{n^2} \frac{n(n+1)}{2} + \frac{4}{n}(n) = 16 \left(1 + \frac{1}{n} \right) + 4.$$

Therefore,

$$A = \lim_{n \rightarrow \infty} S_n = \lim_{n \rightarrow \infty} \left[16 \left(1 + \frac{1}{n} \right) + 4 \right] = 16 \lim_{n \rightarrow \infty} \left(1 + \frac{1}{n} \right) + 4 = 16(1) + 4 = \boxed{20}.$$

- (c) The work required in part (b) was easier than part (a). When working with the right endpoint of each subinterval, calculations are done on a simpler expression involving i instead of $i-1$.
26. Let $f(x) = 3x + 1$, and consider the area under the graph of f from $a = 0$ to $b = 4$. Partition the interval $[0, 4]$ into n subintervals

$$[x_0, x_1], [x_1, x_2], \dots, [x_{i-1}, x_i], \dots, [x_{n-1}, x_n]$$

where

$$0 = x_0 < x_1 < x_2 < \dots < x_i < \dots < x_{n-1} < x_n = 4$$

and each subinterval is of length

$$\Delta x = \frac{4-0}{n} = \frac{4}{n}.$$

The coordinates of the endpoints of each subinterval are

$$\begin{aligned} x_0 = 0, x_1 = \frac{4}{n}, x_2 = 2 \left(\frac{4}{n} \right), \dots, x_{i-1} = (i-1) \left(\frac{4}{n} \right), \\ x_i = i \left(\frac{4}{n} \right), \dots, x_n = n \left(\frac{4}{n} \right) = 4. \end{aligned}$$

- (a) To approximate the area under the graph of f using lower sums, we must find the absolute minimum value of f on each subinterval. Because f is an increasing function, the absolute minimum on each subinterval occurs at the left endpoint of the subinterval. Thus,

$$c_i = x_{i-1} = (i-1) \left(\frac{4}{n} \right),$$

and

$$s_n = \sum_{i=1}^n f(c_i) \Delta x = \sum_{i=1}^n \left(3(i-1) \left(\frac{4}{n} \right) + 1 \right) \frac{4}{n} = \sum_{i=1}^n \left(\frac{48i}{n^2} - \frac{48}{n^2} + \frac{4}{n} \right).$$

Using summation properties,

$$\begin{aligned} s_n &= \frac{48}{n^2} \sum_{i=1}^n i - \frac{48}{n^2} \sum_{i=1}^n 1 + \frac{4}{n} \sum_{i=1}^n 1 \\ &= \frac{48}{n^2} \frac{n(n+1)}{2} - \frac{48}{n^2}(n) + \frac{4}{n}(n) = 24 \left(1 + \frac{1}{n} \right) - \frac{48}{n} + 4. \end{aligned}$$

Therefore,

$$\begin{aligned} A &= \lim_{n \rightarrow \infty} s_n = \lim_{n \rightarrow \infty} \left[24 \left(1 + \frac{1}{n} \right) - \frac{48}{n} + 4 \right] = 24 \lim_{n \rightarrow \infty} \left(1 + \frac{1}{n} \right) - 48 \lim_{n \rightarrow \infty} \frac{1}{n} + 4 \\ &= 24(1) - 48(0) + 4 = \boxed{28}. \end{aligned}$$

- (b) To approximate the area under the graph of f using upper sums, we must find the absolute maximum value of f on each subinterval. Because f is an increasing function, the absolute maximum on each subinterval occurs at the right endpoint of the subinterval. Thus,

$$C_i = x_i = i \left(\frac{4}{n} \right),$$

and

$$S_n = \sum_{i=1}^n f(C_i) \Delta x = \sum_{i=1}^n \left(3i \left(\frac{4}{n} \right) + 1 \right) \frac{4}{n} = \sum_{i=1}^n \left(\frac{48i}{n^2} + \frac{4}{n} \right).$$

Using summation properties,

$$S_n = \frac{48}{n^2} \sum_{i=1}^n i + \frac{4}{n} \sum_{i=1}^n 1 = \frac{48}{n^2} \frac{n(n+1)}{2} + \frac{4}{n}(n) = 24 \left(1 + \frac{1}{n} \right) + 4.$$

Therefore,

$$A = \lim_{n \rightarrow \infty} S_n = \lim_{n \rightarrow \infty} \left[24 \left(1 + \frac{1}{n} \right) + 4 \right] = 24 \lim_{n \rightarrow \infty} \left(1 + \frac{1}{n} \right) + 4 = 24(1) + 4 = \boxed{28}.$$

- (c) The work required in part (b) was easier than part (a). When working with the right endpoint of each subinterval, calculations are done on a simpler expression involving i instead of $i-1$.

27. Let $f(x) = 12 - 3x$, and consider the area under the graph of f from $a = 0$ to $b = 4$. Partition the interval $[0, 4]$ into n subintervals

$$[x_0, x_1], [x_1, x_2], \dots, [x_{i-1}, x_i], \dots, [x_{n-1}, x_n]$$

where

$$0 = x_0 < x_1 < x_2 < \dots < x_i < \dots < x_{n-1} < x_n = 4$$

and each subinterval is of length

$$\Delta x = \frac{4 - 0}{n} = \frac{4}{n}.$$

The coordinates of the endpoints of each subinterval are

$$x_0 = 0, x_1 = \frac{4}{n}, x_2 = 2 \left(\frac{4}{n} \right), \dots, x_{i-1} = (i-1) \left(\frac{4}{n} \right),$$

$$x_i = i \left(\frac{4}{n} \right), \dots, x_n = n \left(\frac{4}{n} \right) = 4.$$

- (a) To approximate the area under the graph of f using lower sums, we must find the absolute minimum value of f on each subinterval. Because f is a decreasing function, the absolute minimum on each subinterval occurs at the right endpoint of the subinterval. Thus,

$$c_i = x_i = i \left(\frac{4}{n} \right),$$

and

$$s_n = \sum_{i=1}^n f(c_i) \Delta x = \sum_{i=1}^n \left(12 - 3 \left(\frac{4i}{n} \right) \right) \frac{4}{n} = \sum_{i=1}^n \left(\frac{48}{n} - \frac{48i}{n^2} \right).$$

Using summation properties,

$$s_n = \frac{48}{n} \sum_{i=1}^n 1 - \frac{48}{n^2} \sum_{i=1}^n i = \frac{48}{n} (n) - \frac{48}{n^2} \frac{n(n+1)}{2} = 48 - 24 \left(1 + \frac{1}{n} \right).$$

Therefore,

$$A = \lim_{n \rightarrow \infty} s_n = \lim_{n \rightarrow \infty} \left[48 - 24 \left(1 + \frac{1}{n} \right) \right] = 48 - 24 \lim_{n \rightarrow \infty} \left(1 + \frac{1}{n} \right) = 48 - 24(1) = \boxed{24}.$$

- (b) To approximate the area under the graph of f using upper sums, we must find the absolute maximum value of f on each subinterval. Because f is a decreasing function, the absolute maximum on each subinterval occurs at the left endpoint of the subinterval. Thus,

$$C_i = x_{i-1} = (i-1) \left(\frac{4}{n} \right),$$

and

$$S_n = \sum_{i=1}^n f(C_i) \Delta x = \sum_{i=1}^n \left(12 - 3 \frac{4(i-1)}{n} \right) \frac{4}{n} = \sum_{i=1}^n \left(\frac{48}{n} + \frac{48}{n^2} - \frac{48i}{n^2} \right).$$

Using summation properties,

$$S_n = \left(\frac{48}{n} + \frac{48}{n^2} \right) \sum_{i=1}^n 1 - \frac{48}{n^2} \sum_{i=1}^n i = \left(\frac{48}{n} + \frac{48}{n^2} \right) (n) - \frac{48}{n^2} \frac{n(n+1)}{2} = 48 + \frac{48}{n} - 24 \left(1 + \frac{1}{n} \right).$$

Therefore

$$\begin{aligned} A &= \lim_{n \rightarrow \infty} S_n = \lim_{n \rightarrow \infty} \left[48 + \frac{48}{n} - 24 \left(1 + \frac{1}{n} \right) \right] \\ &= 48 + 48 \lim_{n \rightarrow \infty} \left(\frac{1}{n} \right) - 24 \lim_{n \rightarrow \infty} \left(1 + \frac{1}{n} \right) = 48 + 48(0) - 24(1) = \boxed{24}. \end{aligned}$$

- (c) The work required in part (a) was easier than part (b). When working with the right endpoint of each subinterval, calculations are done on a simpler expression involving i instead of $i-1$.

28. Let $f(x) = 5 - x$, and consider the area under the graph of f from $a = 0$ to $b = 4$. Partition the interval $[0, 4]$ into n subintervals

$$[x_0, x_1], [x_1, x_2], \dots, [x_{i-1}, x_i], \dots, [x_{n-1}, x_n]$$

where

$$0 = x_0 < x_1 < x_2 < \dots < x_i < \dots < x_{n-1} < x_n = 4$$

and each subinterval is of length

$$\Delta x = \frac{4 - 0}{n} = \frac{4}{n}.$$

The coordinates of the endpoints of each subinterval are

$$x_0 = 0, x_1 = \frac{4}{n}, x_2 = 2\left(\frac{4}{n}\right), \dots, x_{i-1} = (i-1)\left(\frac{4}{n}\right),$$

$$x_i = i\left(\frac{4}{n}\right), \dots, x_n = n\left(\frac{4}{n}\right) = 4.$$

- (a) To approximate the area under the graph of f using lower sums, we must find the absolute minimum value of f on each subinterval. Because f is a decreasing function, the absolute minimum on each subinterval occurs at the right endpoint of the subinterval. Thus,

$$c_i = x_i = i\left(\frac{4}{n}\right),$$

and

$$s_n = \sum_{i=1}^n f(c_i) \Delta x = \sum_{i=1}^n \left(5 - \left(\frac{4i}{n}\right)\right) \frac{4}{n} = \sum_{i=1}^n \left(\frac{20}{n} - \frac{16i}{n^2}\right).$$

Using summation properties,

$$s_n = \frac{20}{n} \sum_{i=1}^n 1 - \frac{16}{n^2} \sum_{i=1}^n i = \frac{20}{n} (n) - \frac{16}{n^2} \frac{n(n+1)}{2} = 20 - 8 \left(1 + \frac{1}{n}\right).$$

Therefore,

$$A = \lim_{n \rightarrow \infty} s_n = \lim_{n \rightarrow \infty} \left[20 - 8 \left(1 + \frac{1}{n}\right)\right] = 20 - 8 \lim_{n \rightarrow \infty} \left(1 + \frac{1}{n}\right) = 20 - 8(1) = \boxed{12}.$$

- (b) To approximate the area under the graph of f using upper sums, we must find the absolute maximum value of f on each subinterval. Because f is a decreasing function, the absolute maximum on each subinterval occurs at the left endpoint of the subinterval. Thus,

$$C_i = x_{i-1} = (i-1)\left(\frac{4}{n}\right),$$

and

$$S_n = \sum_{i=1}^n f(C_i) \Delta x = \sum_{i=1}^n \left(5 - \frac{4(i-1)}{n}\right) \frac{4}{n} = \sum_{i=1}^n \left(\frac{20}{n} + \frac{16}{n^2} - \frac{16i}{n^2}\right).$$

Using summation properties,

$$\begin{aligned} S_n &= \left(\frac{20}{n} + \frac{16}{n^2}\right) \sum_{i=1}^n 1 - \frac{16}{n^2} \sum_{i=1}^n i = \left(\frac{20}{n} + \frac{16}{n^2}\right) (n) - \frac{16}{n^2} \frac{n(n+1)}{2} \\ &= 20 + \frac{16}{n} - 8 \left(1 + \frac{1}{n}\right). \end{aligned}$$

Therefore

$$\begin{aligned}
 A &= \lim_{n \rightarrow \infty} S_n = \lim_{n \rightarrow \infty} \left[20 + \frac{16}{n} - 8 \left(1 + \frac{1}{n} \right) \right] \\
 &= 20 + 16 \lim_{n \rightarrow \infty} \left(\frac{1}{n} \right) - 8 \lim_{n \rightarrow \infty} \left(1 + \frac{1}{n} \right) \\
 &= 20 + 16(0) - 8(1) = \boxed{12}.
 \end{aligned}$$

- (c) The work required in part (a) was easier than part (b). When working with the right endpoint of each subinterval, calculations are done on a simpler expression involving i instead of $i - 1$.

29. Let $f(x) = 4x^2$, and consider the area under the graph of f from $a = 0$ to $b = 2$. Partition the interval $[0, 2]$ into n subintervals

$$[x_0, x_1], [x_1, x_2], \dots, [x_{i-1}, x_i], \dots, [x_{n-1}, x_n]$$

where

$$0 = x_0 < x_1 < x_2 < \dots < x_i < \dots < x_{n-1} < x_n = 2$$

and each subinterval is of length

$$\Delta x = \frac{2 - 0}{n} = \frac{2}{n}.$$

The coordinates of the endpoints of each subinterval are

$$\begin{aligned}
 x_0 = 0, x_1 = \frac{2}{n}, x_2 = 2 \left(\frac{2}{n} \right), \dots, x_{i-1} = (i-1) \left(\frac{2}{n} \right), \\
 x_i = i \left(\frac{2}{n} \right), \dots, x_n = n \left(\frac{2}{n} \right) = 2.
 \end{aligned}$$

- (a) To approximate the area under the graph of f using lower sums, we must find the absolute minimum value of f on each subinterval. Because f is an increasing function, the absolute minimum on each subinterval occurs at the left endpoint of the subinterval. Thus,

$$c_i = x_{i-1} = (i-1) \left(\frac{2}{n} \right),$$

and

$$s_n = \sum_{i=1}^n f(c_i) \Delta x = \sum_{i=1}^n 4 \left[(i-1) \left(\frac{2}{n} \right) \right]^2 \frac{2}{n} = \sum_{i=1}^n \left(\frac{32}{n^3} i^2 - \frac{64}{n^3} i + \frac{32}{n^3} \right).$$

Using summation properties,

$$\begin{aligned}
 s_n &= \frac{32}{n^3} \sum_{i=1}^n i^2 - \frac{64}{n^3} \sum_{i=1}^n i + \frac{32}{n^3} \sum_{i=1}^n 1 \\
 &= \frac{32}{n^3} \frac{n(n+1)(2n+1)}{6} - \frac{64}{n^3} \frac{n(n+1)}{2} + \frac{32}{n^3} (n) \\
 &= \frac{16}{3} \left(1 + \frac{1}{n} \right) \left(2 + \frac{1}{n} \right) - 32 \left(\frac{1}{n} + \frac{1}{n^2} \right) + \frac{32}{n^2}.
 \end{aligned}$$

Therefore,

$$\begin{aligned}
 A &= \lim_{n \rightarrow \infty} s_n = \lim_{n \rightarrow \infty} \left[\frac{16}{3} \left(1 + \frac{1}{n} \right) \left(2 + \frac{1}{n} \right) - 32 \left(\frac{1}{n} + \frac{1}{n^2} \right) + \frac{32}{n^2} \right] \\
 &= \frac{16}{3} \lim_{n \rightarrow \infty} \left(1 + \frac{1}{n} \right) \left(2 + \frac{1}{n} \right) - 32 \lim_{n \rightarrow \infty} \left(\frac{1}{n} + \frac{1}{n^2} \right) + \lim_{n \rightarrow \infty} \frac{32}{n^2} \\
 &= \frac{16}{3} (2) - 32 (0) + (0) = \boxed{\frac{32}{3}}.
 \end{aligned}$$

- (b) To approximate the area under the graph of f using upper sums, we must find the absolute maximum value of f on each subinterval. Because f is an increasing function, the absolute maximum on each subinterval occurs at the right endpoint of the subinterval. Thus,

$$C_i = x_i = i \left(\frac{2}{n} \right),$$

and

$$S_n = \sum_{i=1}^n f(C_i) \Delta x = \sum_{i=1}^n 4 \left[i \left(\frac{2}{n} \right) \right]^2 \frac{2}{n} = \sum_{i=1}^n \frac{32}{n^3} i^2.$$

Using summation properties,

$$S_n = \frac{32}{n^3} \sum_{i=1}^n i^2 = \frac{32}{n^3} \frac{n(n+1)(2n+1)}{6} = \frac{16}{3} \left(1 + \frac{1}{n} \right) \left(2 + \frac{1}{n} \right).$$

Therefore,

$$\begin{aligned}
 A &= \lim_{n \rightarrow \infty} S_n = \lim_{n \rightarrow \infty} \left[\frac{16}{3} \left(1 + \frac{1}{n} \right) \left(2 + \frac{1}{n} \right) \right] \\
 &= \frac{16}{3} \lim_{n \rightarrow \infty} \left(1 + \frac{1}{n} \right) \left(2 + \frac{1}{n} \right) = \frac{16}{3} (2) = \boxed{\frac{32}{3}}.
 \end{aligned}$$

- (c) The work required in part (b) was easier than part (a). When working with the right endpoint of each subinterval, calculations are done on a simpler expression involving i instead of $i - 1$.

30. Let $f(x) = \frac{1}{2}x^2$, and consider the area under the graph of f from $a = 0$ to $b = 3$. Partition the interval $[0, 3]$ into n subintervals

$$[x_0, x_1], [x_1, x_2], \dots, [x_{i-1}, x_i], \dots, [x_{n-1}, x_n]$$

where

$$0 = x_0 < x_1 < x_2 < \dots < x_i < \dots < x_{n-1} < x_n = 3$$

and each subinterval is of length

$$\Delta x = \frac{3 - 0}{n} = \frac{3}{n}.$$

The coordinates of the endpoints of each subinterval are

$$\begin{aligned}
 x_0 &= 0, x_1 = \frac{3}{n}, x_2 = 2 \left(\frac{3}{n} \right), \dots, x_{i-1} = (i-1) \left(\frac{3}{n} \right), \\
 x_i &= i \left(\frac{3}{n} \right), \dots, x_n = n \left(\frac{3}{n} \right) = 3.
 \end{aligned}$$

- (a) To approximate the area under the graph of f using lower sums, we must find the absolute minimum value of f on each subinterval. Because f is an increasing function, the absolute minimum on each subinterval occurs at the left endpoint of the subinterval. Thus,

$$c_i = x_{i-1} = (i-1) \left(\frac{3}{n} \right),$$

and

$$s_n = \sum_{i=1}^n f(c_i) \Delta x = \sum_{i=1}^n \frac{1}{2} \left[(i-1) \left(\frac{3}{n} \right) \right]^2 \frac{3}{n} = \sum_{i=1}^n \left(\frac{27}{2n^3} i^2 - \frac{27}{n^3} i + \frac{27}{2n^3} \right).$$

Using summation properties,

$$\begin{aligned} s_n &= \frac{27}{2n^3} \sum_{i=1}^n i^2 - \frac{27}{n^3} \sum_{i=1}^n i + \frac{27}{2n^3} \sum_{i=1}^n 1 = \frac{27}{2n^3} \frac{n(n+1)(2n+1)}{6} - \frac{27}{n^3} \frac{n(n+1)}{2} + \frac{27}{2n^3} (n) \\ &= \frac{9}{4} \left(1 + \frac{1}{n} \right) \left(2 + \frac{1}{n} \right) - \frac{27}{2} \left(\frac{1}{n} + \frac{1}{n^2} \right) + \frac{27}{2n^2}. \end{aligned}$$

Therefore,

$$\begin{aligned} A &= \lim_{n \rightarrow \infty} s_n = \lim_{n \rightarrow \infty} \left[\frac{9}{4} \left(1 + \frac{1}{n} \right) \left(2 + \frac{1}{n} \right) - \frac{27}{2} \left(\frac{1}{n} + \frac{1}{n^2} \right) + \frac{27}{2n^2} \right] \\ &= \frac{9}{4} \lim_{n \rightarrow \infty} \left(1 + \frac{1}{n} \right) \left(2 + \frac{1}{n} \right) - \frac{27}{2} \lim_{n \rightarrow \infty} \left(\frac{1}{n} + \frac{1}{n^2} \right) + \frac{27}{2} \lim_{n \rightarrow \infty} \frac{1}{n^2} \\ &= \frac{9}{4} (2) - \frac{27}{2} (0) + \frac{27}{2} (0) = \boxed{\frac{9}{2}}. \end{aligned}$$

- (b) To approximate the area under the graph of f using upper sums, we must find the absolute maximum value of f on each subinterval. Because f is an increasing function, the absolute maximum on each subinterval occurs at the right endpoint of the subinterval. Thus,

$$C_i = x_i = i \left(\frac{3}{n} \right),$$

and

$$S_n = \sum_{i=1}^n f(C_i) \Delta x = \sum_{i=1}^n \frac{1}{2} \left[i \left(\frac{3}{n} \right) \right]^2 \frac{3}{n} = \sum_{i=1}^n \left(\frac{27i}{2n^3} i^2 \right).$$

Using summation properties,

$$S_n = \frac{27}{2n^3} \sum_{i=1}^n i^2 = \frac{27}{2n^3} \frac{n(n+1)(2n+1)}{6} = \frac{9}{4} \left(1 + \frac{1}{n} \right) \left(2 + \frac{1}{n} \right).$$

Therefore,

$$\begin{aligned} A &= \lim_{n \rightarrow \infty} S_n = \lim_{n \rightarrow \infty} \left[\frac{9}{4} \left(1 + \frac{1}{n} \right) \left(2 + \frac{1}{n} \right) \right] \\ &= \frac{9}{4} \lim_{n \rightarrow \infty} \left(1 + \frac{1}{n} \right) \left(2 + \frac{1}{n} \right) = \frac{9}{4} (2) = \boxed{\frac{9}{2}}. \end{aligned}$$

- (c) The work required in part (b) was easier than part (a). When working with the right endpoint of each subinterval, calculations are done on a simpler expression involving i instead of $i-1$.

31. Let $f(x) = 4 - x^2$, and consider the area under the graph of f from $a = 0$ to $b = 2$. Partition the interval $[0, 2]$ into n subintervals

$$[x_0, x_1], [x_1, x_2], \dots, [x_{i-1}, x_i], \dots, [x_{n-1}, x_n]$$

where

$$0 = x_0 < x_1 < x_2 < \dots < x_i < \dots < x_{n-1} < x_n = 2$$

and each subinterval is of length

$$\Delta x = \frac{2 - 0}{n} = \frac{2}{n}.$$

The coordinates of the endpoints of each subinterval are

$$\begin{aligned} x_0 = 0, x_1 = \frac{2}{n}, x_2 = 2 \left(\frac{2}{n} \right), \dots, x_{i-1} = (i-1) \left(\frac{2}{n} \right), \\ x_i = i \left(\frac{2}{n} \right), \dots, x_n = n \left(\frac{2}{n} \right) = 2. \end{aligned}$$

- (a) To approximate the area under the graph of f using lower sums, we must find the absolute minimum value of f on each subinterval. Because f is a decreasing function, the absolute minimum on each subinterval occurs at the right endpoint of the subinterval. Thus,

$$c_i = x_i = i \left(\frac{2}{n} \right),$$

and

$$s_n = \sum_{i=1}^n f(c_i) \Delta x = \sum_{i=1}^n \left(4 - \left(\frac{2i}{n} \right)^2 \right) \frac{2}{n} = \sum_{i=1}^n \left(\frac{8}{n} - \frac{8}{n^3} i^2 \right).$$

Using summation properties,

$$s_n = \frac{8}{n} \sum_{i=1}^n 1 - \frac{8}{n^3} \sum_{i=1}^n i^2 = \frac{8}{n} (n) - \frac{8}{n^3} \frac{n(n+1)(2n+1)}{6} = 8 - \frac{4}{3} \left(1 + \frac{1}{n} \right) \left(2 + \frac{1}{n} \right).$$

Therefore,

$$\begin{aligned} A &= \lim_{n \rightarrow \infty} s_n = \lim_{n \rightarrow \infty} \left[8 - \frac{4}{3} \left(1 + \frac{1}{n} \right) \left(2 + \frac{1}{n} \right) \right] \\ &= 8 - \frac{4}{3} \lim_{n \rightarrow \infty} \left(1 + \frac{1}{n} \right) \left(2 + \frac{1}{n} \right) = 8 - \frac{4}{3} (1)(2) = \boxed{\frac{16}{3}}. \end{aligned}$$

- (b) To approximate the area under the graph of f using upper sums, we must find the absolute maximum value of f on each subinterval. Because f is a decreasing function, the absolute maximum on each subinterval occurs at the left endpoint of the subinterval. Thus,

$$C_i = x_{i-1} = (i-1) \left(\frac{2}{n} \right),$$

and

$$S_n = \sum_{i=1}^n f(C_i) \Delta x = \sum_{i=1}^n \left(4 - \left(\frac{2(i-1)}{n} \right)^2 \right) \frac{2}{n} = \sum_{i=1}^n \left(\frac{8}{n} - \frac{8}{n^3} + \frac{16}{n^3} i - \frac{8}{n^3} i^2 \right).$$

Using summation properties,

$$\begin{aligned}
 S_n &= \left(\frac{8}{n} - \frac{8}{n^3}\right) \sum_{i=1}^n 1 + \frac{16}{n^3} \sum_{i=1}^n i - \frac{8}{n^3} \sum_{i=1}^n i^2 \\
 &= \left(\frac{8}{n} - \frac{8}{n^3}\right)(n) + \frac{16}{n^3} \frac{n(n+1)}{2} - \frac{8}{n^3} \frac{n(n+1)(2n+1)}{6} \\
 &= 8 - \frac{8}{n^2} + 8\left(\frac{1}{n} + \frac{1}{n^2}\right) - \frac{4}{3}\left(1 + \frac{1}{n}\right)\left(2 + \frac{1}{n}\right).
 \end{aligned}$$

Therefore,

$$\begin{aligned}
 A &= \lim_{n \rightarrow \infty} S_n = \lim_{n \rightarrow \infty} \left[8 - \frac{8}{n^2} + 8\left(\frac{1}{n} + \frac{1}{n^2}\right) - \frac{4}{3}\left(1 + \frac{1}{n}\right)\left(2 + \frac{1}{n}\right) \right] \\
 &= 8 - 8 \lim_{n \rightarrow \infty} \left(\frac{1}{n^2}\right) + 8 \lim_{n \rightarrow \infty} \left(\frac{1}{n} + \frac{1}{n^2}\right) - \frac{4}{3} \lim_{n \rightarrow \infty} \left(1 + \frac{1}{n}\right)\left(2 + \frac{1}{n}\right) \\
 &= 8 - 8(0) + 8(0) - \frac{4}{3}(2) = \boxed{\frac{16}{3}}.
 \end{aligned}$$

- (c) The work required in part (a) was easier than part (b). When working with the right endpoint of each subinterval, calculations are done on a simpler expression involving i instead of $i - 1$.
32. Let $f(x) = 12 - x^2$, and consider the area under the graph of f from $a = 0$ to $b = 3$. Partition the interval $[0, 3]$ into n subintervals

$$[x_0, x_1], [x_1, x_2], \dots, [x_{i-1}, x_i], \dots, [x_{n-1}, x_n]$$

where

$$0 = x_0 < x_1 < x_2 < \dots < x_i < \dots < x_{n-1} < x_n = 3$$

and each subinterval is of length

$$\Delta x = \frac{3 - 0}{n} = \frac{3}{n}.$$

The coordinates of the endpoints of each subinterval are

$$\begin{aligned}
 x_0 = 0, x_1 = \frac{3}{n}, x_2 = 2\left(\frac{3}{n}\right), \dots, x_{i-1} = (i-1)\left(\frac{3}{n}\right), \\
 x_i = i\left(\frac{3}{n}\right), \dots, x_n = n\left(\frac{3}{n}\right) = 3.
 \end{aligned}$$

- (a) To approximate the area under the graph of f using lower sums, we must find the absolute minimum value of f on each subinterval. Because f is a decreasing function, the absolute minimum on each subinterval occurs at the right endpoint of the subinterval. Thus,

$$c_i = x_i = i\left(\frac{3}{n}\right),$$

and

$$s_n = \sum_{i=1}^n f(c_i) \Delta x = \sum_{i=1}^n \left(12 - \left(\frac{3i}{n}\right)^2\right) \frac{3}{n} = \sum_{i=1}^n \left(\frac{36}{n} - \frac{27}{n^3} i^2\right).$$

Using summation properties,

$$s_n = \frac{36}{n} \sum_{i=1}^n 1 - \frac{27}{n^3} \sum_{i=1}^n i^2 = \frac{36}{n} (n) - \frac{27}{n^3} \frac{n(n+1)(2n+1)}{6} = 36 - \frac{9}{2} \left(1 + \frac{1}{n}\right) \left(2 + \frac{1}{n}\right).$$

Therefore,

$$\begin{aligned} A &= \lim_{n \rightarrow \infty} s_n = \lim_{n \rightarrow \infty} \left[36 - \frac{9}{2} \left(1 + \frac{1}{n}\right) \left(2 + \frac{1}{n}\right) \right] \\ &= 36 - \frac{9}{2} \lim_{n \rightarrow \infty} \left(1 + \frac{1}{n}\right) \left(2 + \frac{1}{n}\right) = 36 - \frac{9}{2} (1)(2) = \boxed{27}. \end{aligned}$$

- (b) To approximate the area under the graph of f using upper sums, we must find the absolute maximum value of f on each subinterval. Because f is a decreasing function, the absolute maximum on each subinterval occurs at the left endpoint of the subinterval. Thus,

$$C_i = x_{i-1} = (i-1) \left(\frac{3}{n}\right),$$

and

$$S_n = \sum_{i=1}^n f(C_i) \Delta x = \sum_{i=1}^n \left(12 - \left(\frac{3(i-1)}{n} \right)^2 \right) \frac{3}{n} = \sum_{i=1}^n \left(\frac{36}{n} - \frac{27}{n^3} + \frac{54}{n^3} i - \frac{27}{n^3} i^2 \right).$$

Using summation properties,

$$\begin{aligned} S_n &= \left(\frac{36}{n} - \frac{27}{n^3} \right) \sum_{i=1}^n 1 + \frac{54}{n^3} \sum_{i=1}^n i - \frac{27}{n^3} \sum_{i=1}^n i^2 \\ &= \left(\frac{36}{n} - \frac{27}{n^3} \right) (n) + \frac{54}{n^3} \frac{n(n+1)}{2} - \frac{27}{n^3} \frac{n(n+1)(2n+1)}{6} \\ &= 36 - \frac{27}{n^2} + 27 \left(\frac{1}{n} + \frac{1}{n^2} \right) - \frac{9}{2} \left(1 + \frac{1}{n} \right) \left(2 + \frac{1}{n} \right). \end{aligned}$$

Therefore,

$$\begin{aligned} A &= \lim_{n \rightarrow \infty} S_n = \lim_{n \rightarrow \infty} \left[36 - \frac{27}{n^2} + 27 \left(\frac{1}{n} + \frac{1}{n^2} \right) - \frac{9}{2} \left(1 + \frac{1}{n} \right) \left(2 + \frac{1}{n} \right) \right] \\ &= 36 - 27 \lim_{n \rightarrow \infty} \left(\frac{1}{n^2} \right) + 27 \lim_{n \rightarrow \infty} \left(\frac{1}{n} + \frac{1}{n^2} \right) - \frac{9}{2} \lim_{n \rightarrow \infty} \left(1 + \frac{1}{n} \right) \left(2 + \frac{1}{n} \right) \\ &= 36 + 27(0) - \frac{9}{2} (2) = \boxed{27}. \end{aligned}$$

- (c) The work required in part (a) was easier than part (b). When working with the right endpoint of each subinterval, calculations are done on a simpler expression involving i instead of $i-1$.

Applications and Extensions

33. Let $f(x) = x+3$, and consider the area under the graph of f from $a = 1$ to $b = 3$. Partition the interval $[1, 3]$ into n subintervals

$$[x_0, x_1], [x_1, x_2], \dots, [x_{i-1}, x_i], \dots, [x_{n-1}, x_n]$$

where

$$1 = x_0 < x_1 < x_2 < \cdots < x_i < \cdots < x_{n-1} < x_n = 3$$

and each subinterval is of length

$$\Delta x = \frac{3-1}{n} = \frac{2}{n}.$$

The coordinates of the endpoints of each subinterval are

$$\begin{aligned} x_0 = 1, x_1 = 1 + \frac{2}{n}, x_2 = 1 + 2\left(\frac{2}{n}\right), \dots, x_{i-1} = 1 + (i-1)\left(\frac{2}{n}\right), \\ x_i = 1 + i\left(\frac{2}{n}\right), \dots, x_n = 1 + n\left(\frac{2}{n}\right) = 3. \end{aligned}$$

Because f is an increasing function on the interval $[1, 3]$, the function value at the right endpoint of each subinterval is the absolute maximum value on that subinterval. Thus,

$$C_i = x_i = 1 + \frac{2i}{n},$$

and

$$\begin{aligned} S_n &= \sum_{i=1}^n f(C_i) \Delta x = \sum_{i=1}^n f\left(1 + \frac{2i}{n}\right) \left(\frac{2}{n}\right) = \sum_{i=1}^n \left[\left(1 + \frac{2i}{n}\right) + 3\right] \left(\frac{2}{n}\right) = \sum_{i=1}^n \left(\frac{8}{n} + \frac{4i}{n^2}\right) \\ &= \frac{8}{n} \sum_{i=1}^n 1 + \frac{4}{n^2} \sum_{i=1}^n i = \frac{8}{n}(n) + \frac{4}{n^2} \frac{n(n+1)}{2} = 8 + 2\left(1 + \frac{1}{n}\right). \end{aligned}$$

Finally,

$$A = \lim_{n \rightarrow \infty} S_n = \lim_{n \rightarrow \infty} \left[8 + 2\left(1 + \frac{1}{n}\right)\right] = \boxed{10}.$$

34. Let $f(x) = 3 - x$, and consider the area under the graph of f from $a = 1$ to $b = 3$. Partition the interval $[1, 3]$ into n subintervals

$$[x_0, x_1], [x_1, x_2], \dots, [x_{i-1}, x_i], \dots, [x_{n-1}, x_n]$$

where

$$1 = x_0 < x_1 < x_2 < \cdots < x_i < \cdots < x_{n-1} < x_n = 3$$

and each subinterval is of length

$$\Delta x = \frac{3-1}{n} = \frac{2}{n}.$$

The coordinates of the endpoints of each subinterval are

$$\begin{aligned} x_0 = 1, x_1 = 1 + \frac{2}{n}, x_2 = 1 + 2\left(\frac{2}{n}\right), \dots, x_{i-1} = 1 + (i-1)\left(\frac{2}{n}\right), \\ x_i = 1 + i\left(\frac{2}{n}\right), \dots, x_n = 1 + n\left(\frac{2}{n}\right) = 3. \end{aligned}$$

Because f is a decreasing function on the interval $[1, 3]$, the function value at the right endpoint of each subinterval is the absolute minimum value on that subinterval. Thus,

$$c_i = x_i = 1 + \frac{2i}{n},$$

and

$$\begin{aligned} s_n &= \sum_{i=1}^n f(c_i) \Delta x = \sum_{i=1}^n f\left(1 + \frac{2i}{n}\right) \left(\frac{2}{n}\right) = \sum_{i=1}^n \left[3 - \left(1 + \frac{2i}{n}\right)\right] \left(\frac{2}{n}\right) = \sum_{i=1}^n \left(\frac{4}{n} - \frac{4i}{n^2}\right) \\ &= \frac{4}{n} \sum_{i=1}^n 1 - \frac{4}{n^2} \sum_{i=1}^n i = \frac{4}{n} (n) - \frac{4}{n^2} \frac{n(n+1)}{2} = 4 - 2 \left(1 + \frac{1}{n}\right). \end{aligned}$$

Finally,

$$A = \lim_{n \rightarrow \infty} s_n = \lim_{n \rightarrow \infty} \left[4 - 2 \left(1 + \frac{1}{n}\right)\right] = \boxed{2}.$$

35. Let $f(x) = 2x + 5$, and consider the area under the graph of f from $a = -1$ to $b = 2$. Partition the interval $[-1, 2]$ into n subintervals

$$[x_0, x_1], [x_1, x_2], \dots, [x_{i-1}, x_i], \dots, [x_{n-1}, x_n]$$

where

$$-1 = x_0 < x_1 < x_2 < \dots < x_i < \dots < x_{n-1} < x_n = 2$$

and each subinterval is of length

$$\Delta x = \frac{2 - (-1)}{n} = \frac{3}{n}.$$

The coordinates of the endpoints of each subinterval are

$$\begin{aligned} x_0 &= -1, x_1 = -1 + \frac{3}{n}, x_2 = -1 + 2 \left(\frac{3}{n}\right), \dots, x_{i-1} = -1 + (i-1) \left(\frac{3}{n}\right), \\ x_i &= -1 + i \left(\frac{3}{n}\right), \dots, x_n = -1 + n \left(\frac{3}{n}\right) = 2. \end{aligned}$$

Because f is an increasing function on the interval $[-1, 2]$, the function value at the right endpoint of each subinterval is the absolute maximum value on that subinterval. Thus,

$$C_i = x_i = -1 + \frac{3i}{n},$$

and

$$\begin{aligned} S_n &= \sum_{i=1}^n f(C_i) \Delta x = \sum_{i=1}^n f\left(-1 + \frac{3i}{n}\right) \left(\frac{3}{n}\right) = \sum_{i=1}^n \left[2 \left(-1 + \frac{3i}{n}\right) + 5\right] \left(\frac{3}{n}\right) \\ &= \sum_{i=1}^n \left(\frac{9}{n} + \frac{18i}{n^2}\right) = \frac{9}{n} \sum_{i=1}^n 1 + \frac{18}{n^2} \sum_{i=1}^n i = \frac{9}{n} (n) + \frac{18}{n^2} \frac{n(n+1)}{2} = 9 + 9 \left(1 + \frac{1}{n}\right). \end{aligned}$$

Finally,

$$A = \lim_{n \rightarrow \infty} S_n = \lim_{n \rightarrow \infty} \left[9 + 9 \left(1 + \frac{1}{n}\right)\right] = \boxed{18}.$$

36. Let $f(x) = 2 - 3x$, and consider the area under the graph of f from $a = -2$ to $b = 0$. Partition the interval $[-2, 0]$ into n subintervals

$$[x_0, x_1], [x_1, x_2], \dots, [x_{i-1}, x_i], \dots, [x_{n-1}, x_n]$$

where

$$-2 = x_0 < x_1 < x_2 < \dots < x_i < \dots < x_{n-1} < x_n = 0$$

and each subinterval is of length

$$\Delta x = \frac{0 - (-2)}{n} = \frac{2}{n}.$$

The coordinates of the endpoints of each subinterval are

$$\begin{aligned} x_0 &= -2, x_1 = -2 + \frac{2}{n}, x_2 = -2 + 2\left(\frac{2}{n}\right), \dots, x_{i-1} = -2 + (i-1)\left(\frac{2}{n}\right), \\ x_i &= -2 + i\left(\frac{2}{n}\right), \dots, x_n = -2 + n\left(\frac{2}{n}\right) = 0. \end{aligned}$$

Because f is a decreasing function on the interval $[-2, 0]$, the function value at the right endpoint of each subinterval is the absolute minimum value on that subinterval. Thus,

$$c_i = x_i = -2 + \frac{2i}{n},$$

and

$$\begin{aligned} s_n &= \sum_{i=1}^n f(c_i) \Delta x = \sum_{i=1}^n f\left(-2 + \frac{2i}{n}\right) \left(\frac{2}{n}\right) = \sum_{i=1}^n \left[2 - 3\left(-2 + \frac{2i}{n}\right)\right] \left(\frac{2}{n}\right) \\ &= \sum_{i=1}^n \left(\frac{16}{n} - \frac{12i}{n^2}\right) = \frac{16}{n} \sum_{i=1}^n 1 - \frac{12}{n^2} \sum_{i=1}^n i = \frac{16}{n} (n) - \frac{12}{n^2} \frac{n(n+1)}{2} = 16 - 6\left(1 + \frac{1}{n}\right). \end{aligned}$$

Finally,

$$A = \lim_{n \rightarrow \infty} s_n = \lim_{n \rightarrow \infty} \left[16 - 6\left(1 + \frac{1}{n}\right)\right] = \boxed{10}.$$

37. Let $f(x) = 2x^2 + 1$, and consider the area under the graph of f from $a = 1$ to $b = 3$. Partition the interval $[1, 3]$ into n subintervals

$$[x_0, x_1], [x_1, x_2], \dots, [x_{i-1}, x_i], \dots, [x_{n-1}, x_n]$$

where

$$1 = x_0 < x_1 < x_2 < \dots < x_i < \dots < x_{n-1} < x_n = 3$$

and each subinterval is of length

$$\Delta x = \frac{3 - 1}{n} = \frac{2}{n}.$$

The coordinates of the endpoints of each subinterval are

$$\begin{aligned} x_0 &= 1, x_1 = 1 + \frac{2}{n}, x_2 = 1 + 2\left(\frac{2}{n}\right), \dots, x_{i-1} = 1 + (i-1)\left(\frac{2}{n}\right), \\ x_i &= 1 + i\left(\frac{2}{n}\right), \dots, x_n = 1 + n\left(\frac{2}{n}\right) = 3. \end{aligned}$$

Because f is an increasing function on the interval $[1, 3]$, the function value at the right endpoint of each subinterval is the absolute maximum value on that subinterval. Thus,

$$C_i = x_i = 1 + \frac{2i}{n},$$

and

$$\begin{aligned}
S_n &= \sum_{i=1}^n f(C_i) \Delta x = \sum_{i=1}^n f\left(1 + \frac{2i}{n}\right) \left(\frac{2}{n}\right) = \sum_{i=1}^n \left[2 \left(1 + \frac{2i}{n}\right)^2 + 1\right] \left(\frac{2}{n}\right) \\
&= \sum_{i=1}^n \left(\frac{6}{n} + \frac{16}{n^2}i + \frac{16}{n^3}i^2\right) = \frac{6}{n} \sum_{i=1}^n 1 + \frac{16}{n^2} \sum_{i=1}^n i + \frac{16}{n^3} \sum_{i=1}^n i^2 \\
&= \frac{6}{n}(n) + \frac{16}{n^2} \frac{n(n+1)}{2} + \frac{16}{n^3} \frac{n(n+1)(2n+1)}{6} \\
&= 6 + 8 \left(1 + \frac{1}{n}\right) + \frac{8}{3} \left(1 + \frac{1}{n}\right) \left(2 + \frac{1}{n}\right).
\end{aligned}$$

Finally,

$$A = \lim_{n \rightarrow \infty} S_n = \lim_{n \rightarrow \infty} \left[6 + 8 \left(1 + \frac{1}{n}\right) + \frac{8}{3} \left(1 + \frac{1}{n}\right) \left(2 + \frac{1}{n}\right)\right] = \boxed{\frac{58}{3}}.$$

38. Let $f(x) = 4 - x^2$, and consider the area under the graph of f from $a = 1$ to $b = 2$. Partition the interval $[1, 2]$ into n subintervals

$$[x_0, x_1], [x_1, x_2], \dots, [x_{i-1}, x_i], \dots, [x_{n-1}, x_n]$$

where

$$1 = x_0 < x_1 < x_2 < \dots < x_i < \dots < x_{n-1} < x_n = 2$$

and each subinterval is of length

$$\Delta x = \frac{2-1}{n} = \frac{1}{n}.$$

The coordinates of the endpoints of each subinterval are

$$\begin{aligned}
x_0 &= 1, x_1 = 1 + \frac{1}{n}, x_2 = 1 + 2 \left(\frac{1}{n}\right), \dots, x_{i-1} = 1 + (i-1) \left(\frac{1}{n}\right), \\
x_i &= 1 + i \left(\frac{1}{n}\right), \dots, x_n = 1 + n \left(\frac{1}{n}\right) = 2.
\end{aligned}$$

Because f is a decreasing function on the interval $[1, 2]$, the function value at the right endpoint of each subinterval is the absolute minimum value on that subinterval. Thus,

$$c_i = x_i = 1 + \frac{i}{n},$$

and

$$\begin{aligned}
s_n &= \sum_{i=1}^n f(c_i) \Delta x = \sum_{i=1}^n f\left(1 + \frac{i}{n}\right) \left(\frac{1}{n}\right) = \sum_{i=1}^n \left[4 - \left(1 + \frac{i}{n}\right)^2\right] \left(\frac{1}{n}\right) \\
&= \sum_{i=1}^n \left(\frac{3}{n} - \frac{2}{n^2}i - \frac{1}{n^3}i^2\right) = \frac{3}{n} \sum_{i=1}^n 1 - \frac{2}{n^2} \sum_{i=1}^n i - \frac{1}{n^3} \sum_{i=1}^n i^2 \\
&= \frac{3}{n}(n) - \frac{2}{n^2} \frac{n(n+1)}{2} - \frac{1}{n^3} \frac{n(n+1)(2n+1)}{6} \\
&= 3 - \left(1 + \frac{1}{n}\right) - \frac{1}{6} \left(1 + \frac{1}{n}\right) \left(2 + \frac{1}{n}\right).
\end{aligned}$$

Finally,

$$A = \lim_{n \rightarrow \infty} s_n = \lim_{n \rightarrow \infty} \left[3 - \left(1 + \frac{1}{n}\right) - \frac{1}{6} \left(1 + \frac{1}{n}\right) \left(2 + \frac{1}{n}\right)\right] = \boxed{\frac{5}{3}}.$$

39. Let $f(x) = xe^x$, and consider the area under the graph of f from $a = 0$ to $b = 8$. With $n = 20$,

$$\Delta x = \frac{8-0}{20} = \frac{2}{5} \quad \text{and} \quad x_i = 0 + i\Delta x = \frac{2i}{5}.$$

Because f is increasing on the interval $[0, 8]$, the absolute maximum on any subinterval occurs at the right endpoint of the subinterval; that is,

$$C_i = x_i = \frac{2i}{5}.$$

Therefore,

$$\begin{aligned} A &\approx S_{20} = \sum_{i=1}^{20} f(C_i) \Delta x = \sum_{i=1}^{20} f\left(\frac{2i}{5}\right) \left(\frac{2}{5}\right) = \frac{2}{5} \sum_{i=1}^{20} \left(\frac{2i}{5} e^{\frac{2i}{5}}\right) \\ &= \frac{4}{25} \sum_{i=1}^{20} i e^{\frac{2i}{5}} \approx \boxed{25990}. \end{aligned}$$

40. Let $f(x) = \ln x$, and consider the area under the graph of f from $a = 1$ to $b = 3$. With $n = 20$,

$$\Delta x = \frac{3-1}{20} = \frac{1}{10} \quad \text{and} \quad x_i = 1 + i\Delta x = 1 + \frac{i}{10}.$$

Because f is increasing on the interval $[1, 3]$, the absolute maximum on any subinterval occurs at the right endpoint of the subinterval; that is,

$$C_i = x_i = 1 + \frac{i}{10}.$$

Therefore,

$$A \approx S_{20} = \sum_{i=1}^{20} f(C_i) \Delta x = \sum_{i=1}^{20} f\left(1 + \frac{i}{10}\right) \left(\frac{1}{10}\right) = \frac{1}{10} \sum_{i=1}^{20} \ln\left(1 + \frac{i}{10}\right) \approx \boxed{1.350}.$$

41. Let $f(x) = \frac{1}{x}$, and consider the area under the graph of f from $a = 1$ to $b = 5$. With $n = 20$,

$$\Delta x = \frac{5-1}{20} = \frac{1}{5} \quad \text{and} \quad x_i = 1 + i\Delta x = 1 + \frac{i}{5}.$$

Because f is decreasing on the interval $[1, 5]$, the absolute maximum on any subinterval occurs at the left endpoint of the subinterval; that is,

$$C_i = x_{i-1} = 1 + \frac{i-1}{5}.$$

Therefore,

$$A \approx S_{20} = \sum_{i=1}^{20} f(C_i) \Delta x = \sum_{i=1}^{20} f\left(1 + \frac{i-1}{5}\right) \left(\frac{1}{5}\right) = \frac{1}{5} \sum_{i=1}^{20} \frac{1}{1 + \frac{i-1}{5}} \approx \boxed{1.693}.$$

42. Let $f(x) = \frac{1}{x^2}$, and consider the area under the graph of f from $a = 2$ to $b = 6$. With $n = 20$,

$$\Delta x = \frac{6-2}{20} = \frac{1}{5} \quad \text{and} \quad x_i = 2 + i\Delta x = 2 + \frac{i}{5}.$$

Because f is decreasing on the interval $[2, 6]$, the absolute maximum on any subinterval occurs at the left endpoint of the subinterval; that is,

$$C_i = x_{i-1} = 2 + \frac{i-1}{5}.$$

Therefore,

$$A \approx S_{20} = \sum_{i=1}^{20} f(C_i) \Delta x = \sum_{i=1}^{20} f\left(2 + \frac{i-1}{5}\right) \left(\frac{1}{5}\right) = \frac{1}{5} \sum_{i=1}^{20} \frac{1}{\left(2 + \frac{i-1}{5}\right)^2} \approx \boxed{0.356}.$$

43. Let $f(x) = \frac{4}{x}$, and consider the area under the graph of f from 1 to 4.

(a) The graph of f from 1 to 4 is shown below. The area below the graph is shaded.

(b) Partition the interval $[1, 4]$ into n subintervals

$$[x_0, x_1], [x_1, x_2], \dots, [x_{i-1}, x_i], \dots, [x_{n-1}, x_n]$$

where

$$1 = x_0 < x_1 < x_2 < \dots < x_i < \dots < x_{n-1} < x_n = 4$$

and each subinterval is of length

$$\Delta x = \frac{4-1}{n} = \frac{3}{n}.$$

The coordinates of the endpoints of each subinterval are

$$x_0 = 1, x_1 = 1 + \frac{3}{n}, x_2 = 1 + 2\left(\frac{3}{n}\right), \dots, x_{i-1} = 1 + (i-1)\left(\frac{3}{n}\right),$$

$$x_i = 1 + i\left(\frac{3}{n}\right), \dots, x_n = 1 + n\left(\frac{3}{n}\right) = 4.$$

(c) To approximate the area under the graph of f using lower sums, we must find the absolute minimum value of f on each subinterval. Because f is a decreasing function, the absolute minimum on each subinterval occurs at the right endpoint of the subinterval. Thus,

$$c_i = x_i = 1 + \left(\frac{3i}{n}\right),$$

and

$$s_n = \sum_{i=1}^n f(c_i) \Delta x = \sum_{i=1}^n f\left(1 + \frac{3i}{n}\right) \Delta x = \sum_{i=1}^n \frac{4}{1 + \frac{3i}{n}} \cdot \frac{3}{n}.$$

- (d) To approximate the area under the graph of f using upper sums, we must find the absolute maximum value of f on each subinterval. Because f is a decreasing function, the absolute maximum on each subinterval occurs at the left endpoint of the subinterval. Thus,

$$C_i = x_{i-1} = 1 + \left(\frac{3(i-1)}{n}\right),$$

and

$$S_n = \sum_{i=1}^n f(C_i) \Delta x = \sum_{i=1}^n f\left(1 + \frac{3(i-1)}{n}\right) \Delta x = \sum_{i=1}^n \frac{4}{1 + \frac{3(i-1)}{n}} \cdot \frac{3}{n}.$$

- (e) Using the computer algebra system *Mathematica* to evaluate the sums from parts (c) and (d), we find

n	5	10	50	100
s_n	4.754	5.123	5.456	5.500
S_n	6.554	6.023	5.636	5.590

- (f) Because $s_n \leq A \leq S_n$ for all n , it follows that

$$5.500 \approx s_{100} \leq A \leq S_{100} \approx 5.590.$$

Challenge Problems

44. Let $f(x) = x$, and consider the area under the graph of f from $a \geq 0$ to b . With n subintervals each of length

$$\Delta x = \frac{b-a}{n},$$

it follows that

$$x_i = a + i\Delta x = a + i\frac{b-a}{n}.$$

To approximate the area under the graph of f using lower sums, we must find the absolute minimum value of f on each subinterval. Because f is an increasing function, the absolute minimum on each subinterval occurs at the left endpoint of the subinterval. Thus,

$$c_i = x_{i-1} = a + (i-1)\left(\frac{b-a}{n}\right),$$

and

$$\begin{aligned} s_n &= \sum_{i=1}^n f(c_i) \Delta x = \sum_{i=1}^n f\left(a + (i-1)\frac{b-a}{n}\right) \left(\frac{b-a}{n}\right) \\ &= \sum_{i=1}^n \left(a + (i-1)\frac{b-a}{n}\right) \left(\frac{b-a}{n}\right) = a\left(\frac{b-a}{n}\right) \sum_{i=1}^n 1 + \left(\frac{b-a}{n}\right)^2 \sum_{i=1}^n (i-1) \end{aligned}$$

By shifting the index of summation,

$$\sum_{i=1}^n (i-1) = \sum_{j=0}^{n-1} j = \sum_{j=1}^{n-1} j = \frac{(n-1)n}{2}.$$

Therefore,

$$\begin{aligned}
 s_n &= a \left(\frac{b-a}{n} \right) (n) + \left(\frac{b-a}{n} \right)^2 \frac{(n-1)n}{2} \\
 &= a(b-a) + \frac{(b-a)^2}{2} \left(1 - \frac{1}{n} \right) = a(b-a) + \frac{(b-a)^2}{2} - \frac{(b-a)^2}{2n} \\
 &= (b-a) \left(a + \frac{b-a}{2} \right) - \frac{(b-a)^2}{2n} = (b-a) \left(\frac{b+a}{2} \right) - \frac{(b-a)^2}{2n} \\
 &= \frac{b^2 - a^2}{2} - \frac{(b-a)^2}{2n}.
 \end{aligned}$$

To approximate the area under the graph of f using upper sums, we must find the absolute maximum value of f on each subinterval. Because f is an increasing function, the absolute maximum on each subinterval occurs at the right endpoint of the subinterval. Thus,

$$C_i = x_i = a + i \left(\frac{b-a}{n} \right),$$

and

$$\begin{aligned}
 S_n &= \sum_{i=1}^n f(C_i) \Delta x = \sum_{i=1}^n f \left(a + i \frac{b-a}{n} \right) \left(\frac{b-a}{n} \right) = \sum_{i=1}^n \left(a + i \frac{b-a}{n} \right) \left(\frac{b-a}{n} \right) \\
 &= a \left(\frac{b-a}{n} \right) \sum_{i=1}^n 1 + \left(\frac{b-a}{n} \right)^2 \sum_{i=1}^n i = a \left(\frac{b-a}{n} \right) (n) + \left(\frac{b-a}{n} \right)^2 \frac{n(n+1)}{2} \\
 &= a(b-a) + \frac{(b-a)^2}{2} \left(1 + \frac{1}{n} \right) = a(b-a) + \frac{(b-a)^2}{2} + \frac{(b-a)^2}{2n} \\
 &= (b-a) \left(a + \frac{b-a}{2} \right) + \frac{(b-a)^2}{2n} = (b-a) \left(\frac{b+a}{2} \right) + \frac{(b-a)^2}{2n} \\
 &= \frac{b^2 - a^2}{2} + \frac{(b-a)^2}{2n}.
 \end{aligned}$$

Because $b > a$, $(b-a)^2 > 0$ and

$$s_n = \frac{b^2 - a^2}{2} - \frac{(b-a)^2}{2n} < \frac{b^2 - a^2}{2} < \frac{b^2 - a^2}{2} + \frac{(b-a)^2}{2n} = S_n.$$

45. Let $f(x) = x^2$, and consider the area under the graph of f from $a \geq 0$ to b . With n subintervals each of length

$$\Delta x = \frac{b-a}{n},$$

it follows that

$$x_i = a + i\Delta x = a + i \frac{b-a}{n}.$$

To approximate the area under the graph of f using lower sums, we must find the absolute minimum value of f on each subinterval. Because $a \geq 0$, f is an increasing function on the interval $[a, b]$, and the absolute minimum on each subinterval occurs at the left endpoint of the subinterval. Thus,

$$c_i = x_{i-1} = a + (i-1) \left(\frac{b-a}{n} \right),$$

and

$$\begin{aligned} s_n &= \sum_{i=1}^n f(c_i) \Delta x = \sum_{i=1}^n f\left(a + (i-1) \frac{b-a}{n}\right) \left(\frac{b-a}{n}\right) = \sum_{i=1}^n \left(a + (i-1) \frac{b-a}{n}\right)^2 \left(\frac{b-a}{n}\right) \\ &= a^2 \left(\frac{b-a}{n}\right) \sum_{i=1}^n 1 + 2a \left(\frac{b-a}{n}\right)^2 \sum_{i=1}^n (i-1) + \left(\frac{b-a}{n}\right)^3 \sum_{i=1}^n (i-1)^2. \end{aligned}$$

By shifting the index of summation,

$$\sum_{i=1}^n (i-1) = \sum_{j=0}^{n-1} j = \sum_{j=1}^{n-1} j = \frac{(n-1)n}{2}$$

and

$$\sum_{i=1}^n (i-1)^2 = \sum_{j=0}^{n-1} j^2 = \sum_{j=1}^{n-1} j^2 = \frac{(n-1)n(2n-1)}{6}.$$

Therefore,

$$\begin{aligned} s_n &= a^2 \left(\frac{b-a}{n}\right) (n) + 2a \left(\frac{b-a}{n}\right)^2 \frac{n(n-1)}{2} + \left(\frac{b-a}{n}\right)^3 \frac{n(n-1)(2n-1)}{6} \\ &= a^2 (b-a) + a (b-a)^2 \left(1 - \frac{1}{n}\right) + \frac{(b-a)^3}{6} \left(1 - \frac{1}{n}\right) \left(2 - \frac{1}{n}\right) \\ &= a^2 (b-a) + a (b-a)^2 + \frac{(b-a)^3}{3} - \frac{a (b-a)^2}{n} - \frac{(b-a)^3}{2n} + \frac{(b-a)^3}{6n^2} \\ &= \frac{b-a}{3} \left(3a^2 + 3a(b-a) + (b-a)^2\right) - \frac{(b-a)^2}{2n} (2a + b - a) + \frac{(b-a)^3}{6n^2} \\ &= \frac{b-a}{3} (a^2 + ab + b^2) - \frac{(b-a)^2}{2n} (a + b) + \frac{(b-a)^3}{6n^2} \\ &= \frac{b^3 - a^3}{3} - \frac{(b-a)^2}{2n} (a + b) + \frac{(b-a)^3}{6n^2}. \end{aligned}$$

To approximate the area under the graph of f using upper sums, we must find the absolute maximum value of f on each subinterval. Because $a \geq 0$, f is an increasing function on the interval $[a, b]$, and the absolute maximum on each subinterval occurs at the right endpoint of the subinterval. Thus,

$$C_i = x_i = a + i \left(\frac{b-a}{n}\right),$$

and

$$\begin{aligned}
S_n &= \sum_{i=1}^n f(C_i) \Delta x = \sum_{i=1}^n f\left(a + i \frac{b-a}{n}\right) \left(\frac{b-a}{n}\right) = \sum_{i=1}^n \left(a + i \frac{b-a}{n}\right)^2 \left(\frac{b-a}{n}\right) \\
&= \sum_{i=1}^n a^2 \left(\frac{b-a}{n}\right) + 2a \left(\frac{b-a}{n}\right)^2 \sum_{i=1}^n i + \left(\frac{b-a}{n}\right)^3 \sum_{i=1}^n i^2 \\
&= a^2 \left(\frac{b-a}{n}\right) (n) + 2a \left(\frac{b-a}{n}\right)^2 \frac{n(n+1)}{2} + \left(\frac{b-a}{n}\right)^3 \frac{n(n+1)(2n+1)}{6} \\
&= a^2(b-a) + a(b-a)^2 \left(1 + \frac{1}{n}\right) + \frac{(b-a)^3}{6} \left(1 + \frac{1}{n}\right) \left(2 + \frac{1}{n}\right) \\
&= a^2(b-a) + a(b-a)^2 + \frac{(b-a)^3}{3} + \frac{a(b-a)^2}{n} + \frac{(b-a)^3}{2n} + \frac{(b-a)^3}{6n^2} \\
&= \frac{b-a}{3} \left(3a^2 + 3a(b-a) + (b-a)^2\right) + \frac{(b-a)^2}{2n} (2a + b - a) + \frac{(b-a)^3}{6n^2} \\
&= \frac{b-a}{3} (a^2 + ab + b^2) + \frac{(b-a)^2}{2n} (a+b) + \frac{(b-a)^3}{6n^2} \\
&= \frac{b^3 - a^3}{3} + \frac{(b-a)^2}{2n} (a+b) + \frac{(b-a)^3}{6n^2}.
\end{aligned}$$

Because $a \geq 0$ and $b > a$,

$$\begin{aligned}
-\frac{(b-a)^2}{2n} (a+b) + \frac{(b-a)^3}{6n^2} &= -\frac{(b-a)^2}{2n} \left[(a+b) - \frac{b-a}{3n} \right] \\
&= -\frac{(b-a)^2}{2n} \left[a \left(1 + \frac{1}{3n}\right) + b \left(1 - \frac{1}{3n}\right) \right] < 0,
\end{aligned}$$

so

$$s_n = \frac{b^3 - a^3}{3} - \frac{(b-a)^2}{2n} (a+b) + \frac{(b-a)^3}{6n^2} < \frac{b^3 - a^3}{3} < \frac{b^3 - a^3}{3} + \frac{(b-a)^2}{2n} (a+b) + \frac{(b-a)^3}{6n^2} = S_n.$$

46. Let $f(x) = \frac{H}{B}x$ on the interval $[0, B]$. The region under the graph of f is then a right triangle with base B and height H . With n subintervals each of length

$$\Delta x = \frac{B-0}{n} = \frac{B}{n},$$

it follows that

$$x_i = a + i\Delta x = \frac{Bi}{n}.$$

To approximate the area under the graph of f using lower sums, we must find the absolute minimum value of f on each subinterval. Because f is an increasing function, the absolute minimum on each subinterval occurs at the left endpoint of the subinterval. Thus,

$$c_i = x_{i-1} = \frac{B(i-1)}{n},$$

$$\begin{aligned}
s_n &= \sum_{i=1}^n f(c_i) \Delta x = \sum_{i=1}^n f\left(\frac{B(i-1)}{n}\right) \left(\frac{B}{n}\right) = \sum_{i=1}^n \left(\frac{H}{B} \frac{B(i-1)}{n}\right) \left(\frac{B}{n}\right) \\
&= \frac{HB}{n^2} \sum_{i=1}^n (i-1) = \frac{HB}{n^2} \sum_{i=1}^n i - \frac{HB}{n^2} (n) = \frac{HB}{n^2} \frac{n(n+1)}{2} - \frac{HB}{n} \\
&= \frac{1}{2} HB \left(1 + \frac{1}{n}\right) - \frac{HB}{n},
\end{aligned}$$

and

$$A = \lim_{n \rightarrow \infty} s_n = \lim_{n \rightarrow \infty} \left[\frac{1}{2}HB \left(1 + \frac{1}{n} \right) - \frac{HB}{n} \right] = \boxed{\frac{1}{2}HB}.$$

To approximate the area under the graph of f using upper sums, we must find the absolute maximum value of f on each subinterval. Because f is an increasing function, the absolute maximum on each subinterval occurs at the right endpoint of the subinterval. Thus,

$$C_i = x_i = \frac{Bi}{n},$$

$$\begin{aligned} S_n &= \sum_{i=1}^n f(C_i) \Delta x = \sum_{i=1}^n f\left(\frac{Bi}{n}\right) \left(\frac{B}{n}\right) = \sum_{i=1}^n \left(\frac{H}{B} \frac{Bi}{n}\right) \left(\frac{B}{n}\right) \\ &= \frac{HB}{n^2} \sum_{i=1}^n i = \frac{HB}{n^2} \sum_{i=1}^n i = \frac{HB}{n^2} \frac{n(n+1)}{2} = \frac{1}{2}HB \left(1 + \frac{1}{n} \right), \end{aligned}$$

and

$$A = \lim_{n \rightarrow \infty} S_n = \lim_{n \rightarrow \infty} \left[\frac{1}{2}HB \left(1 + \frac{1}{n} \right) \right] = \boxed{\frac{1}{2}HB}.$$

47. Let $f(x) = H_1 + \frac{H_2 - H_1}{B}x$ on the interval $[0, B]$. The region under the graph of f is then a trapezoid of heights H_1 and H_2 and base B . With n subintervals each of length

$$\Delta x = \frac{B - 0}{n} = \frac{B}{n},$$

it follows that

$$x_i = a + i\Delta x = \frac{Bi}{n}.$$

To approximate the area under the graph of f using lower sums, we must find the absolute minimum value of f on each subinterval. Because f is an increasing function, the absolute minimum on each subinterval occurs at the left endpoint of the subinterval. Thus,

$$c_i = x_{i-1} = \frac{B(i-1)}{n},$$

$$\begin{aligned} s_n &= \sum_{i=1}^n f(c_i) \Delta x = \sum_{i=1}^n f\left(\frac{B(i-1)}{n}\right) \left(\frac{B}{n}\right) = \sum_{i=1}^n \left(H_1 + \frac{H_2 - H_1}{B} \frac{B(i-1)}{n} \right) \left(\frac{B}{n}\right) \\ &= \frac{H_1 B}{n} \sum_{i=1}^n 1 + \frac{(H_2 - H_1)B}{n^2} \sum_{i=1}^n (i-1) \\ &= \frac{H_1 B}{n} (n) + \frac{(H_2 - H_1)B}{n^2} \sum_{i=1}^n i - \frac{(H_2 - H_1)B}{n^2} (n) \\ &= H_1 B + \frac{(H_2 - H_1)B}{n^2} \frac{n(n+1)}{2} - \frac{(H_2 - H_1)B}{n} \\ &= H_1 B + \frac{1}{2}(H_2 - H_1)B \left(1 + \frac{1}{n} \right) - \frac{(H_2 - H_1)B}{n}, \end{aligned}$$

and

$$A = \lim_{n \rightarrow \infty} s_n = \lim_{n \rightarrow \infty} \left[H_1 B + \frac{1}{2}(H_2 - H_1)B \left(1 + \frac{1}{n} \right) - \frac{(H_2 - H_1)B}{n} \right] = \boxed{\frac{1}{2}(H_2 + H_1)B}.$$

To approximate the area under the graph of f using upper sums, we must find the absolute maximum value of f on each subinterval. Because f is an increasing function, the absolute maximum on each subinterval occurs at the right endpoint of the subinterval. Thus,

$$C_i = x_i = \frac{Bi}{n},$$

$$\begin{aligned} S_n &= \sum_{i=1}^n f(C_i) \Delta x = \sum_{i=1}^n f\left(\frac{Bi}{n}\right) \left(\frac{B}{n}\right) = \sum_{i=1}^n \left(H_1 + \frac{H_2 - H_1}{B} \frac{Bi}{n}\right) \left(\frac{B}{n}\right) \\ &= \frac{H_1 B}{n} \sum_{i=1}^n 1 + \frac{(H_2 - H_1) B}{n^2} \sum_{i=1}^n i \\ &= \frac{H_1 B}{n} (n) + \frac{(H_2 - H_1) B}{n^2} \frac{n(n+1)}{2} \\ &= H_1 B + \frac{1}{2} (H_2 - H_1) B \left(1 + \frac{1}{n}\right), \end{aligned}$$

and

$$A = \lim_{n \rightarrow \infty} S_n = \lim_{n \rightarrow \infty} \left[H_1 B + \frac{1}{2} (H_2 - H_1) B \left(1 + \frac{1}{n}\right) \right] = \boxed{\frac{1}{2} (H_2 + H_1) B}.$$

Chapter 6: Applications of the Integral

6.1: Area Between Graphs

Concepts and Vocabulary

1. The two graphs meet at $x = 0$ and at $x = 1$, and in the interval $[0, 1]$, we have $\sqrt{x} \geq x^2$, so the integral is $\int_0^1 (\sqrt{x} - x^2) dx$. See the figure below:

2. Partitioning the y -axis, the two graphs meet at $y = -1$ and again at $y = 1$; when $-1 \leq y \leq 1$, we have $y^2 \leq 1$, so the integral is $\int_{-1}^1 (1 - y^2) dy$.

Skill Building

3. The region is shown below:

Partitioning along the x -axis, we have $x \leq 2x$, so the area is

$$\int_0^1 (2x - x) dx = \int_0^1 x dx = \left[\frac{1}{2}x^2 \right]_0^1 = \frac{1}{2} - 0 = \boxed{\frac{1}{2}}.$$

4. The region is shown below:

Partitioning along the x -axis, we have $x \leq 3x$, so the area is

$$\int_0^3 (3x - x) dx = \int_0^3 2x dx = [x^2]_0^3 = 9 - 0 = \boxed{9}.$$

5. The region is shown below:

The two curves intersect when $x^2 = x$, so when $x = 0$ and $x = 1$. Partitioning along the x -axis, we have $x^2 \leq x$, so the area is

$$\int_0^1 (x - x^2) dx = \left[\frac{1}{2}x^2 - \frac{1}{3}x^3 \right]_0^1 = \left(\frac{1}{2} - \frac{1}{3} \right) - (0 - 0) = \boxed{\frac{1}{6}}.$$

6. The region is shown below:

The two curves intersect when $x^2 = 4x$, so when $x = 0$ and $x = 4$. Partitioning along the x -axis, we have $x^2 \leq 4x$, so the area is

$$\int_0^4 (4x - x^2) dx = \left[2x^2 - \frac{1}{3}x^3 \right]_0^4 = \left(32 - \frac{64}{3} \right) - (0 - 0) = \boxed{\frac{32}{3}}.$$

7. The region is shown below:

Partitioning along the x -axis, we have $e^{-x} \leq e^x$, so the area is

$$\int_0^{\ln 2} (e^x - e^{-x}) dx = [e^x + e^{-x}]_0^{\ln 2} = (e^{\ln 2} + e^{-\ln 2}) - (e^0 + e^0) = \left(2 + \frac{1}{2} \right) - (1 + 1) = \boxed{\frac{1}{2}}.$$

8. The region is shown below:

Partitioning along the x -axis, we have $-x + 1 \leq e^x$, so the area is

$$\begin{aligned} \int_0^1 (e^x - (-x + 1)) dx &= \int_0^1 (e^x + x - 1) dx = \left[e^x + \frac{1}{2}x^2 - x \right]_0^1 \\ &= \left(e^1 + \frac{1}{2} - 1 \right) - (e^0 + 0 - 0) = \boxed{e - \frac{3}{2}}. \end{aligned}$$

9. The region is shown below:

The two curves intersect when $x^2 = x^4$, so when $x = -1$, $x = 0$, and $x = 1$. Partitioning along the x -axis, we have $x^4 \leq x^2$, so the area is

$$\int_{-1}^1 (x^2 - x^4) dx = \left[\frac{1}{3}x^3 - \frac{1}{5}x^5 \right]_{-1}^1 = \left(\frac{1}{3} - \frac{1}{5} \right) - \left(-\frac{1}{3} + \frac{1}{5} \right) = \boxed{\frac{4}{15}}.$$

10. The region is shown below:

The two curves intersect when $x = x^3$, so when $x = -1$, $x = 0$, and $x = 1$. Since the region between $x = -1$ and $x = 0$ is below the x -axis, we compute the area from $x = 0$ to $x = 1$ and double it so that we count that area as positive. Partitioning along the x -axis, we have $x^3 \leq x$, so the area is

$$2 \int_0^1 (x - x^3) dx = 2 \left[\frac{1}{2}x^2 - \frac{1}{4}x^4 \right]_0^1 = 2 \left(\left(\frac{1}{2} - \frac{1}{4} \right) - (0 - 0) \right) = \boxed{\frac{1}{2}}.$$

11. The region is shown below:

Partitioning along the x -axis, we have $\frac{1}{2} \leq \cos x$, so the area is

$$\int_0^{\pi/3} \left(\cos x - \frac{1}{2} \right) dx = \left[\sin x - \frac{1}{2}x \right]_0^{\pi/3} = \left(\sin \frac{\pi}{3} - \frac{1}{2} \cdot \frac{\pi}{3} \right) - (\sin 0 - 0) = \boxed{\frac{\sqrt{3}}{2} - \frac{\pi}{6}}.$$

12. The region is shown below:

The two curves intersect when $\sin x = \frac{1}{2}$, so at $(\frac{\pi}{6}, \frac{1}{2})$ and $(\frac{5\pi}{6}, \frac{1}{2})$. Partitioning along the x -axis, we have $\frac{1}{2} \leq \sin x$, so the area is

$$\begin{aligned} \int_{\pi/6}^{5\pi/6} \left(\sin x - \frac{1}{2} \right) dx &= \left[-\cos x - \frac{1}{2}x \right]_{\pi/6}^{5\pi/6} = \left(-\cos \frac{5\pi}{6} - \frac{1}{2} \cdot \frac{5\pi}{6} \right) - \left(-\cos \frac{\pi}{6} - \frac{1}{2} \cdot \frac{\pi}{6} \right) \\ &= \left(\frac{\sqrt{3}}{2} - \frac{5\pi}{12} \right) - \left(-\frac{\sqrt{3}}{2} - \frac{\pi}{12} \right) = \boxed{\sqrt{3} - \frac{\pi}{3}}. \end{aligned}$$

13. The region is shown below:

The two curves intersect when $2 - y = y^2$, so when $y^2 + y - 2 = (y + 2)(y - 1) = 0$; this happens at the points $(1, 1)$ and $(4, -2)$. Partitioning along the y -axis, we have $y^2 \leq 2 - y$, so the area is

$$\int_{-2}^1 (2 - y - y^2) dy = \left[2y - \frac{1}{2}y^2 - \frac{1}{3}y^3 \right]_{-2}^1 = \left(2 - \frac{1}{2} - \frac{1}{3} \right) - \left(-4 - 2 + \frac{8}{3} \right) = \boxed{\frac{9}{2}}.$$

14. The region is shown below:

The two curves intersect when $y + 2 = y^2$, so when $y^2 - y - 2 = (y - 2)(y + 1) = 0$; this happens at the points $(4, 2)$ and $(1, -1)$. Partitioning along the y -axis, we have $y^2 \leq y + 2$, so the area is

$$\int_{-1}^2 (y + 2 - y^2) dy = \left[\frac{1}{2}y^2 + 2y - \frac{1}{3}y^3 \right]_{-1}^2 = \left(2 + 4 - \frac{8}{3} \right) - \left(\frac{1}{2} - 2 + \frac{1}{3} \right) = \boxed{\frac{9}{2}}.$$

15. The region is shown below:

The two curves intersect where $9 - y^2 = 5$, so when $y = -2$ and $y = 2$. Partitioning along the y -axis, we have $5 \leq 9 - y^2$, so the area is

$$\int_{-2}^2 (9 - y^2 - 5) dy = \int_{-2}^2 (4 - y^2) dy = \left[4y - \frac{1}{3}y^3 \right]_{-2}^2 = \left(8 - \frac{8}{3} \right) - \left(-8 + \frac{8}{3} \right) = \boxed{\frac{32}{3}}.$$

16. The region is shown below:

The two curves intersect where $16 - y^2 = 7$, so when $y = -3$ and $y = 3$. Partitioning along the y -axis, we have $7 \leq 16 - y^2$, so the area is

$$\int_{-3}^3 (16 - y^2 - 7) dy = \int_{-3}^3 (9 - y^2) dy = \left[9y - \frac{1}{3}y^3 \right]_{-3}^3 = (27 - 9) - (-27 + 9) = \boxed{36}.$$

17. The region is shown below:

Solve the second equation for x to get $x = y + 6$. The two curves intersect where $y^2 + 4 = y + 6$, so when $y^2 - y - 2 = (y - 2)(y + 1) = 0$. Therefore the intersection points are $(8, 2)$ and $(5, -1)$. Partitioning along the y -axis, we see that $y^2 + 4 \leq y + 6$, so the area is

$$\begin{aligned} \int_{-1}^2 (y + 6 - (y^2 + 4)) dy &= \int_{-1}^2 (-y^2 + y + 2) dy = \left[-\frac{1}{3}y^3 + \frac{1}{2}y^2 + 2y \right]_{-1}^2 \\ &= \left(-\frac{8}{3} + 2 + 4 \right) - \left(\frac{1}{3} + \frac{1}{2} - 2 \right) = \boxed{\frac{9}{2}}. \end{aligned}$$

18. The region is shown below:

Solve the second equation for x to get $x = 8 - y$. The two curves intersect where $y^2 + 6 = 8 - y$, so when $y^2 + y - 2 = (y + 2)(y - 1) = 0$. Therefore the intersection points are $(7, 1)$ and $(10, -2)$. Partitioning along the y -axis, we see that $y^2 + 6 \leq 8 - y$, so the area is

$$\begin{aligned} \int_{-2}^1 (8 - y - (y^2 + 6)) \, dy &= \int_{-2}^1 (-y^2 - y + 2) \, dy = \left[-\frac{1}{3}y^3 - \frac{1}{2}y^2 + 2y \right]_{-2}^1 \\ &= \left(-\frac{1}{3} - \frac{1}{2} + 2 \right) - \left(\frac{8}{3} - 2 - 4 \right) = \boxed{\frac{9}{2}}. \end{aligned}$$

19. The region is shown below:

Solving $y = \ln x$ for x gives $x = e^y$. Then partitioning along the y -axis, we see that $1 \leq e^y$, so the area is

$$\int_0^2 (e^y - 1) \, dy = [e^y - y]_0^2 = (e^2 - 2) - (e^0 - 0) = \boxed{e^2 - 3}.$$

20. The region is shown below:

Solving $y = \ln x$ for x gives $x = e^y$. Then partitioning along the y -axis, we see that $e^y \leq e$, so the area is

$$\int_0^1 (e - e^y) dy = [ey - e^y]_0^1 = (e - e) - (0 - 1) = \boxed{1}.$$

21. This region is bounded above by $y = \cos x$ and below by $y = -\sin x$, and it extends from $x = -\frac{\pi}{4}$ to $x = \frac{3\pi}{4}$. So we integrate by subdividing along the x axis, and we get

$$\begin{aligned} \int_{-\pi/4}^{3\pi/4} (\cos x - (-\sin x)) dx &= \int_{-\pi/4}^{3\pi/4} (\cos x + \sin x) dx = [\sin x - \cos x]_{-\pi/4}^{3\pi/4} \\ &= \left(\frac{\sqrt{2}}{2} - \left(-\frac{\sqrt{2}}{2} \right) \right) - \left(-\frac{\sqrt{2}}{2} - \frac{\sqrt{2}}{2} \right) = \boxed{2\sqrt{2}}. \end{aligned}$$

22. This region consists of two areas, one below the x axis and one above. For $x < 0$, we have $\sqrt[3]{x} < x^3$, while for $x > 0$ we have $\sqrt[3]{x} > x^3$. So the total area is

$$\begin{aligned} \int_{-1}^0 (x^3 - \sqrt[3]{x}) dx + \int_0^1 (\sqrt[3]{x} - x^3) dx &= \left[\frac{1}{4}x^4 - \frac{3}{4}x^{4/3} \right]_{-1}^0 + \left[\frac{3}{4}x^{4/3} - \frac{1}{4}x^4 \right]_0^1 \\ &= \left((0 - 0) - \left(\frac{1}{4} - \frac{3}{4} \right) \right) + \left(\left(\frac{3}{4} - \frac{1}{4} \right) - (0 - 0) \right) \\ &= \boxed{1}. \end{aligned}$$

23. If we try to partition along the x -axis, we will require two integrals, one for $-5 \leq x \leq 3$ and the other for $3 \leq x \leq 4$, since the upper bound of the area changes equations at $x = 3$. So we partition along the y -axis. The equation of the parabola is $x = -y^2 + 4$; solving the linear equation for x gives $x = 2y + 1$. Since $-y^2 + 4 \geq 2y + 1$ throughout the region of integration, the area is

$$\begin{aligned} \int_{-3}^1 (-y^2 + 4 - (2y + 1)) dy &= \int_{-3}^1 (-y^2 - 2y + 3) dy = \left[-\frac{1}{3}y^3 - y^2 + 3y \right]_{-3}^1 \\ &= \left(-\frac{1}{3} - 1 + 3 \right) - (9 - 9 - 9) = \boxed{\frac{32}{3}}. \end{aligned}$$

24. Integrate by subdividing along the x -axis. The upper bound is $-x + 3$, while the lower bound is $\frac{4}{x+2}$. So the area is

$$\begin{aligned} \int_{-1}^2 \left(-x + 3 - \frac{4}{x+2} \right) dx &= \left[-\frac{1}{2}x^2 + 3x - 4 \ln|x+2| \right]_{-1}^2 \\ &= (-2 + 6 - 4 \ln 4) - \left(-\frac{1}{2} - 3 - 4 \ln 1 \right) = \boxed{\frac{15}{2} - 4 \ln 4}. \end{aligned}$$

25. The region is shown below:

The two curves intersect when $\sqrt{x} = x^3$, which is at the points $(0, 0)$ and $(1, 1)$. So:

(a) Partitioning the x -axis, the area is

$$\int_0^1 (\sqrt{x} - x^3) dx = \left[\frac{2}{3}x^{3/2} - \frac{1}{4}x^4 \right]_0^1 = \left(\frac{2}{3} - \frac{1}{4} \right) - (0 - 0) = \boxed{\frac{5}{12}}.$$

(b) Partitioning the y -axis, we must first solve the two equations for x . This gives $x = y^2$ and $x = \sqrt[3]{y}$. Then the area between the curves is

$$\int_0^1 (\sqrt[3]{y} - y^2) dy = \left[\frac{3}{4}y^{4/3} - \frac{1}{3}y^3 \right]_0^1 = \left(\frac{3}{4} - \frac{1}{3} \right) - (0 - 0) = \boxed{\frac{5}{12}}.$$

26. The region is shown below:

The two curves intersect when $\sqrt{x} = x^2$, which is at the points $(0, 0)$ and $(1, 1)$. So:

(a) Partitioning the x -axis, the area is

$$\int_0^1 (\sqrt{x} - x^2) dx = \left[\frac{2}{3}x^{3/2} - \frac{1}{3}x^3 \right]_0^1 = \left(\frac{2}{3} - \frac{1}{3} \right) - (0 - 0) = \boxed{\frac{1}{3}}.$$

(b) Partitioning the y -axis, we must first solve the two equations for x . This gives $x = y^2$ and $x = \sqrt{y}$. Then the area between the curves is

$$\int_0^1 (\sqrt{y} - y^2) dy = \left[\frac{2}{3}y^{3/2} - \frac{1}{3}y^3 \right]_0^1 = \left(\frac{2}{3} - \frac{1}{3} \right) - (0 - 0) = \boxed{\frac{1}{3}}.$$

27. The region is shown below:

The curves $y = x^2 + 1$ and $y = x + 1$ intersect when $x^2 + 1 = x + 1$, so when $x^2 = x$. As a result, the intersection points are $(0, 1)$ and $(1, 2)$. So:

(a) Partitioning the x -axis, the area is

$$\int_0^1 ((x + 1) - (x^2 + 1)) dx = \int_0^1 (x - x^2) dx = \left[\frac{1}{2}x^2 - \frac{1}{3}x^3 \right]_0^1 = \left(\frac{1}{2} - \frac{1}{3} \right) - (0 - 0) = \boxed{\frac{1}{6}}.$$

(b) Partitioning the y -axis, we must first solve the two equations for x . This gives $x = \sqrt{y - 1}$ and $x = y - 1$. Then the area between the curves is

$$\begin{aligned} \int_1^2 (\sqrt{y - 1} - (y - 1)) dy &= \int_1^2 (1 - y + \sqrt{y - 1}) dy = \left[y - \frac{1}{2}y^2 + \frac{2}{3}(y - 1)^{3/2} \right]_1^2 \\ &= \left(2 - 2 + \frac{2}{3} \right) - \left(1 - \frac{1}{2} + 0 \right) = \boxed{\frac{1}{6}}. \end{aligned}$$

28. The region is shown below:

The curves $y = x^2 + 1$ and $y = 4x + 1$ intersect when $x^2 + 1 = 4x + 1$, so when $x^2 = 4x$, or at the points $(0, 1)$ and $(4, 17)$. So:

(a) Partitioning the x -axis, the area is

$$\int_0^4 ((4x + 1) - (x^2 + 1)) dx = \int_0^4 (4x - x^2) dx = \left[2x^2 - \frac{1}{3}x^3 \right]_0^4 = \left(32 - \frac{64}{3} \right) - (0 - 0) = \boxed{\frac{32}{3}}.$$

- (b) Partitioning the y -axis, we must first solve the two equations for x . This gives $x = \sqrt{y-1}$ and $x = \frac{y-1}{4}$. Then the area between the curves is

$$\begin{aligned} \int_1^{17} \left(\sqrt{y-1} - \frac{y-1}{4} \right) dy &= \int_1^{17} \left(\sqrt{y-1} - \frac{1}{4}y + \frac{1}{4} \right) dy \\ &= \left[\frac{2}{3}(y-1)^{3/2} - \frac{1}{8}y^2 + \frac{1}{4}y \right]_1^{17} = \left(\frac{128}{3} - \frac{289}{8} + \frac{17}{4} \right) - \left(0 - \frac{1}{8} + \frac{1}{4} \right) = \boxed{\frac{32}{3}}. \end{aligned}$$

29. The region is shown below:

These curves intersect where $9-x = 9-3x$, so at $(0, 3)$. So:

- (a) From $x = 0$ to $x = 3$, the upper bound is $\sqrt{9-x}$ and the lower bound is $\sqrt{9-3x}$, but from $x = 3$ to $x = 9$ the lower bound is 0. Therefore the area is

$$\begin{aligned} \int_0^3 (\sqrt{9-x} - \sqrt{9-3x}) dx + \int_3^9 \sqrt{9-x} dx \\ &= \left[-\frac{2}{3}(9-x)^{3/2} + \frac{2}{9}(9-3x)^{3/2} \right]_0^3 + \left[-\frac{2}{3}(9-x)^{3/2} \right]_3^9 \\ &= \left((-4\sqrt{6} + 0) - (-18 + 6) \right) + \left(0 - (-4\sqrt{6}) \right) = \boxed{12}. \end{aligned}$$

- (b) Solving both equations for x gives $x = 9-y^2$ and $x = 3-\frac{1}{3}y^2$, and the first curve forms the upper bound for integration when subdividing along the y -axis. Then the area is

$$\begin{aligned} \int_0^3 \left((9-y^2) - \left(3 - \frac{1}{3}y^2 \right) \right) dy &= \int_0^3 \left(6 - \frac{2}{3}y^2 \right) dy \\ &= \left[6y - \frac{2}{9}y^3 \right]_0^3 \\ &= (18 - 6) - (0 - 0) = \boxed{12}. \end{aligned}$$

30. The region is shown below:

These curves intersect where $16 - 2x = 16 - 4x$, so at $(0, 4)$.

- (a) From $x = 0$ to $x = 4$, the upper bound is $\sqrt{16 - 2x}$ and the lower bound is $\sqrt{16 - 4x}$, but from $x = 4$ to $x = 8$ the lower bound is 0. Therefore the area is

$$\begin{aligned} \int_0^4 (\sqrt{16 - 2x} - \sqrt{16 - 4x}) dx + \int_4^8 \sqrt{16 - 2x} dx \\ = \left[-\frac{1}{3}(16 - 2x)^{3/2} + \frac{1}{6}(16 - 4x)^{3/2} \right]_0^4 + \left[-\frac{1}{3}(16 - 2x)^{3/2} \right]_4^8 \\ = \left(\left(-\frac{16}{3}\sqrt{2} + 0 \right) - \left(-\frac{64}{3} + \frac{32}{3} \right) \right) + 0 - \left(-\frac{16}{3}\sqrt{2} \right) \\ = \boxed{\frac{32}{3}}. \end{aligned}$$

- (b) Solving both equations for x gives $x = 8 - \frac{1}{2}y^2$ and $x = 4 - \frac{1}{4}y^2$, and the first curve forms the upper bound for integration when subdividing along the y -axis. Then the area is

$$\begin{aligned} \int_0^4 \left(\left(8 - \frac{1}{2}y^2 \right) - \left(4 - \frac{1}{4}y^2 \right) \right) dy &= \int_0^4 \left(4 - \frac{1}{4}y^2 \right) dy \\ &= \left[4y - \frac{1}{12}y^3 \right]_0^4 \\ &= 16 - \frac{16}{3} + (0 - 0) = \boxed{\frac{32}{3}}. \end{aligned}$$

31. The region is shown below:

These curves intersect when $\sqrt{x - 2} = \sqrt{2x - 6}$, so at $x = 4$, which is the point $(4, \sqrt{2})$. Therefore:

- (a) From $x = 2$ to $x = 3$, the lower bound is zero and the upper bound is $\sqrt{x - 2}$; from $x = 3$ to $x = 4$ the lower bound is $\sqrt{2x - 6}$. Therefore the area is

$$\begin{aligned} \int_2^3 \sqrt{x - 2} dx + \int_3^4 (\sqrt{x - 2} - \sqrt{2x - 6}) dy &= \left[\frac{2}{3}(x - 2)^{3/2} \right]_2^3 + \left[\frac{2}{3}(x - 2)^{3/2} - \frac{1}{3}(2x - 6)^{3/2} \right]_3^4 \\ &= \left(\frac{2}{3} - 0 \right) + \left(\left(\frac{4}{3}\sqrt{2} - \frac{2}{3}\sqrt{2} \right) - \left(\frac{2}{3} - 0 \right) \right) \\ &= \boxed{\frac{2}{3}\sqrt{2}}. \end{aligned}$$

- (b) Solving both equations for x gives $x = 3 + \frac{1}{2}y^2$ and $x = 2 + y^2$; the first curve is the upper bound for integration when subdividing along the y -axis. Then the area is

$$\begin{aligned} \int_0^{\sqrt{2}} \left(\left(3 + \frac{1}{2}y^2 \right) - (2 + y^2) \right) dy &= \int_0^{\sqrt{2}} \left(1 - \frac{1}{2}y^2 \right) dy \\ &= \left[y - \frac{1}{6}y^3 \right]_0^{\sqrt{2}} \\ &= \left(\sqrt{2} - \frac{\sqrt{2}}{3} \right) - (0 - 0) \\ &= \boxed{\frac{2}{3}\sqrt{2}}. \end{aligned}$$

32. The region is shown below:

These curves intersect when $2x - 5 = 4x - 17$, so when $x = 6$, at the point $(6, \sqrt{7})$. Therefore:

- (a) From $x = \frac{5}{2}$ to $x = \frac{17}{4}$, the upper bound is $\sqrt{2x-5}$ and the lower bound is 0. From $x = \frac{17}{4}$ to $x = 6$ the lower bound is $\sqrt{4x-17}$. So the area is

$$\begin{aligned} \int_{5/2}^{17/4} \sqrt{2x-5} dx + \int_{17/4}^6 (\sqrt{2x-5} - \sqrt{4x-17}) dx \\ &= \left[\frac{1}{3}(2x-5)^{3/2} \right]_{5/2}^{17/4} + \left[\frac{1}{3}(2x-5)^{3/2} - \frac{1}{6}(4x-17)^{3/2} \right]_{17/4}^6 \\ &= \frac{7}{12}\sqrt{14} + \left(\frac{7}{6}\sqrt{7} - \frac{7}{12}\sqrt{14} \right) \\ &= \boxed{\frac{7}{6}\sqrt{7}}. \end{aligned}$$

- (b) Solving both equations for x gives $x = \frac{y^2+5}{2}$ and $x = \frac{y^2+17}{4}$; the second equation forms the upper bound for the integrand. So the area is

$$\begin{aligned} \int_0^{\sqrt{7}} \left(\frac{y^2+17}{4} - \frac{y^2+5}{2} \right) dy &= \int_0^{\sqrt{7}} \left(\frac{7}{4} - \frac{y^2}{4} \right) dy \\ &= \left[\frac{7}{4}y - \frac{y^3}{12} \right]_0^{\sqrt{7}} \\ &= \left(\frac{7}{4}\sqrt{7} - \frac{7}{12}\sqrt{7} \right) - (0 - 0) \\ &= \boxed{\frac{7}{6}\sqrt{7}}. \end{aligned}$$

33. The region is shown below:

The two graphs intersect when $4 - x^2 = x^2$, so when $x = \pm\sqrt{2}$. Therefore the area between the curves is

$$\int_{-\sqrt{2}}^{\sqrt{2}} (4 - x^2 - x^2) dx = \int_{-\sqrt{2}}^{\sqrt{2}} (4 - 2x^2) dx = \left[4x - \frac{2}{3}x^3 \right]_{-\sqrt{2}}^{\sqrt{2}} = \boxed{\frac{16}{3}\sqrt{2}}.$$

34. The region is shown below:

The graphs intersect when $9 - x^2 = x^2$, so when $x = \pm\frac{3\sqrt{2}}{2}$. Therefore the area between the curves is

$$\int_{-3\sqrt{2}/2}^{3\sqrt{2}/2} (9 - x^2 - x^2) dx = \int_{-3\sqrt{2}/2}^{3\sqrt{2}/2} (9 - 2x^2) dx = \left[9x - \frac{2}{3}x^3 \right]_{-3\sqrt{2}/2}^{3\sqrt{2}/2} = \boxed{18\sqrt{2}}.$$

35. The region is shown below:

For these curves, we partition along the y -axis. The graphs intersect when $y^2 - 4 = 4 - y^2$, which is when $y = -2$ and $y = 2$. So the area between the curves is

$$\int_{-2}^2 ((4 - y^2) - (y^2 - 4)) dy = \int_{-2}^2 (8 - 2y^2) dy = \left[8y - \frac{2}{3}y^3 \right]_{-2}^2 = \boxed{\frac{64}{3}}.$$

36. The region is shown below:

For these curves, we partition along the y -axis. The graphs intersect when $y^2 = 16 - y^2$, so for $y = \pm\sqrt{8} = \pm 2\sqrt{2}$. Therefore the area between the curves is

$$\int_{-2\sqrt{2}}^{2\sqrt{2}} (16 - y^2 - y^2) dy = \int_{-2\sqrt{2}}^{2\sqrt{2}} (16 - 2y^2) dy = \left[16y - \frac{2}{3}y^3 \right]_{-2\sqrt{2}}^{2\sqrt{2}} = \boxed{\frac{128}{3}\sqrt{2}}.$$

37. The region is shown below:

Note that $\ln x^2 = 2 \ln x$. This area can be computed more easily by subdividing along the y -axis. Solving $y = 2 \ln x$ for x gives $x = e^{y/2}$. The line $x = e$ meets this curve at $y = 2$, so the region extends from $y = 0$ to $y = 2$ and is bounded on the left by $e^{y/2}$ and on the right by e . Therefore the area of the region is

$$\int_0^2 (e - e^{y/2}) dy = [ey - 2e^{y/2}]_0^2 = (2e - 2e) - (0 - 2) = \boxed{2}.$$

38. The region is shown below:

We partition along the y -axis so that we do not have to split the computation into two integrals. $y = 1 - x$ becomes $x = 1 - y$, and $y = \ln x$ becomes $x = e^y$. The region extends from $y = 0$ to $y = 1$, so the area of the region is

$$\int_0^1 (e^y - (1 - y)) dy = \int_0^1 (y - 1 + e^y) dy = \left[\frac{1}{2}y^2 - y + e^y \right]_0^1 = \boxed{e - \frac{3}{2}}.$$

39. The region is shown below:

The area of the region is

$$\int_0^{\pi/3} \left(\cos x - \left(1 - \frac{3}{\pi} x \right) \right) dx = \int_0^{\pi/3} \left(\frac{3}{\pi} x - 1 + \cos x \right) dx = \left[\frac{3}{2\pi} x^2 - x + \sin x \right]_0^{\pi/3} = \boxed{\frac{\sqrt{3}}{2} - \frac{\pi}{6}}.$$

40. The region is shown below:

The region extends from $x = 0$ to $x = \frac{\pi}{2}$, so the area is

$$\int_0^{\pi/2} (1 - \sin x) dx = [x + \cos x]_0^{\pi/2} = \boxed{\frac{\pi}{2} - 1}.$$

41. The region is shown below:

The area of the region is

$$\int_0^1 (e^{2x} - 1) dx = \left[\frac{1}{2} e^{2x} - x \right]_0^1 = \boxed{\frac{1}{2} e^2 - \frac{3}{2}}.$$

42. The region is shown below:

The area of the region is

$$\int_0^2 (e^{3x} - e^x) dx = \left[\frac{1}{3}e^{3x} - e^x \right]_0^2 = \boxed{\frac{1}{3}e^6 - e^2 + \frac{2}{3}}.$$

43. The region is shown below:

We partition along the y -axis. Solving these equations for x gives $x = \frac{y^2}{4}$ and $x = 1 + \frac{3}{4}y$. The curves intersect where $y^2 - 3y - 4 = 0$ (since $y^2 = 4x$); this factors as $(y - 4)(y + 1)$, so the y -coordinates of the intersection points are -1 and 4 . Therefore the area of the region is

$$\int_{-1}^4 \left(1 + \frac{3}{4}y - \frac{y^2}{4} \right) dy = \left[y + \frac{3}{8}y^2 - \frac{1}{12}y^3 \right]_{-1}^4 = \boxed{\frac{125}{24}}.$$

44. The region is shown below:

Partition along the y -axis. The two curves have equations $x = \frac{1}{4}(y^2 - 1)$ and $x = y + 1$; these intersect where $y + 1 = \frac{1}{4}(y^2 - 1)$, so when $y^2 - 4y - 5 = 0$. This happens for $y = 5$ and $y = -1$. Therefore the

area of the region is

$$\int_{-1}^5 \left(y + 1 - \frac{1}{4}(y^2 - 1) \right) dy = \int_{-1}^5 \left(-\frac{1}{4}y^2 + y + \frac{5}{4} \right) dy = \left[-\frac{1}{12}y^3 + \frac{1}{2}y^2 + \frac{5}{4}y \right]_{-1}^5 = \boxed{9}.$$

45. The region is shown below:

The graphs intersect at $x = 0$ and again at $x = \frac{\pi}{2}$, where $\sin \frac{\pi}{2} = 1$ and $\frac{2}{\pi}x = \frac{2}{\pi} \cdot \frac{\pi}{2} = 1$. So the area of the region is

$$\int_0^{\pi/2} \left(\sin x - \frac{2}{\pi}x \right) dx = \left[-\cos x - \frac{1}{\pi}x^2 \right]_0^{\pi/2} = \boxed{-\frac{\pi}{4} + 1}.$$

46. The region is shown below:

The intersection point of these graphs has no simple exact form, but is approximately equal to 0.759. So the area of the region is approximately

$$\int_0^{0.759} \left(\cos x - \frac{3}{\pi}x \right) dx = \left[\sin x - \frac{3}{2\pi}x^2 \right]_0^{0.759} \approx \boxed{0.413}.$$

Applications and Extensions

47. The slope of BC is $\frac{4-1}{-2-1} = -1$, so the point of tangency of AD with the parabola is a point where the slope of the tangent to the parabola is -1 . With $y = x^2$, we have $y' = 2x$, so the slope is -1 at $x = -\frac{1}{2}$. Therefore the point of tangency is $(-\frac{1}{2}, \frac{1}{4})$, so the line AD has equation

$$y - \frac{1}{4} = -1 \left(x - \left(-\frac{1}{2} \right) \right), \text{ or } y = -x - \frac{1}{4}.$$

Line BC has equation

$$y - 1 = -1(x - 1), \text{ or } y = -x + 2.$$

So the area of the parallelogram is

$$\int_{-2}^1 \left((-x+2) - \left(-x - \frac{1}{4} \right) \right) dx = \int_{-2}^1 \left(\frac{9}{4} \right) dx = \frac{27}{4}.$$

The shaded area, on the other hand, has area

$$\int_{-2}^1 ((-x+2) - x^2) dx = \int_{-2}^1 (-x^2 - x + 2) dx = \left[-\frac{1}{3}x^3 - \frac{1}{2}x^2 + 2x \right]_{-2}^1 = \frac{9}{2}.$$

Finally, $\frac{27}{4} \cdot \frac{2}{3} = \frac{9}{2}$, and Archimedes' result follows.

48. Subdividing along the x -axis, we get for the area of the region

$$\int_0^{1/2} (8x - x) dx + \int_{1/2}^1 \left(\frac{1}{x^2} - x \right) dx = \left[\frac{7}{2}x^2 \right]_0^{1/2} + \left[-\frac{1}{x} - \frac{1}{2}x^2 \right]_{1/2}^1 = \frac{7}{8} + \frac{5}{8} = \frac{3}{2}.$$

A triangle with base 1 and height h has area $\frac{1}{2} \cdot 1 \cdot h = \frac{h}{2}$; since we want $\frac{h}{2} = \frac{3}{2}$, we have $\boxed{h = 3}$.

49. The two cost curves, with $A(x)$ the upper curve, are shown below:

(a) The area between the curves is

$$\begin{aligned} \int_0^{10} (8020.6596 \cdot 1.0855^x - 4944.6424 \cdot 1.0711^x) dx \\ = \left[\frac{8020.6596}{\ln 1.0855} 1.0855^x - \frac{4944.6424}{\ln 1.0711} 1.0711^x \right]_0^{10} \approx \$53,213. \end{aligned}$$

(b) The total average additional amount of money spent by a family of four in the U.S. for health care exceeded by about \$53,213 the amount spent by a family of four in Canada. Answers may vary.

50. The region is shown below:

The region extends from $x = 0$ to $x = \frac{\pi}{8}$, so the area is

$$\int_0^{\pi/8} (\cos 2x - \sin 2x) dx = \left[\frac{1}{2} \sin 2x + \frac{1}{2} \cos 2x \right]_0^{\pi/8} = \boxed{\frac{\sqrt{2}}{2} - \frac{1}{2}}.$$

51. The region is shown below:

Since it is easier to integrate $\sin y$ than it is to integrate $\sin^{-1} x$, we choose to partition along the y -axis. The two equations are then $x = \sin y$ and $x = y$. The graph of $x = \sin y$ intersects the line $x = \frac{1}{2}$ at $y = \frac{\pi}{6}$, while the graph of $x = y$ intersects that line at $y = \frac{1}{2}$. So for $0 \leq y \leq \frac{1}{2}$, the region is bounded to the right by $x = y$ and to the left by $x = \sin y$, while for $\frac{1}{2} \leq y \leq \frac{\pi}{6}$, it is bounded to the right by $x = \frac{1}{2}$ and to the left by $x = \sin y$. As a result, the total area is

$$\begin{aligned} \int_0^{1/2} (y - \sin y) dy + \int_{1/2}^{\pi/6} \left(\frac{1}{2} - \sin y \right) dy &= \left[\frac{1}{2} y^2 + \cos y \right]_0^{1/2} + \left[\frac{1}{2} y + \cos y \right]_{1/2}^{\pi/6} \\ &= \left(-\frac{7}{8} + \cos \frac{1}{2} \right) + \left(\frac{\pi}{12} + \frac{\sqrt{3}}{2} - \frac{1}{4} - \cos \frac{1}{2} \right) \\ &= \boxed{-\frac{9}{8} + \frac{\sqrt{3}}{2} + \frac{\pi}{12}}. \end{aligned}$$

52. (a) The two curves are shown below:

(b) The curves intersect when $x^2 = \sin x$. Now, $x = 0$ is such a value of x ; using technology we find the other value to be $x \approx 0.877$. The corresponding y values are $y = 0$ and $y = 0.877^2 \approx 0.769$, so the intersection points are $\boxed{(0, 0) \text{ and } (0.877, 0.769)}$.

(c) The area is

$$\int_0^{0.877} (\sin x - x^2) dx = \left[-\cos x - \frac{1}{3} x^3 \right]_0^{0.877} = \boxed{\approx 0.136}.$$

(d) Solving the two equations for x gives $x = \sqrt{y}$ and $x = \sin^{-1} y$. So the area between the curves is

$$\int_0^{0.769} (\sqrt{y} - \sin^{-1} y) dy \approx 0.136.$$

53. (a) The three curves are shown below:

(b) The graphs of $\sin^{-1} x$ and $y = 0$ intersect at the point $(0, 0)$, and $x + y = 1$ and $y = 0$ intersect at the point $(1, 0)$. The third point of intersection is where $y = \sin^{-1} x = 1 - x$; solving $\sin^{-1} x = 1 - x$ using technology gives $x \approx 0.489$, so that $y = 1 - 0.489 = 0.511$, and the intersection point is $\approx (0.489, 0.511)$.

(c) Partitioning along the y -axis allows us to use just one integral, bounded above by $x = 1 - y$ and below by $x = \sin y$, so its area is

$$\int_0^{0.511} (1 - y - \sin y) dy = \left[y - \frac{1}{2}y^2 + \cos y \right]_0^{0.511} \approx 0.253.$$

54. (a) The three curves are shown below:

- (b) The graphs of $\cos^{-1} x$ and $y = 0$ intersect on the x -axis, at $(1, 0)$, and $y = x^3 + 1$ and $y = 0$ intersect on the x -axis, at $(-1, 0)$. The third point of intersection is determined by solving $\cos^{-1} x = x^3 + 1$; using technology we get $x \approx 0.457$, so that $y \approx 0.457^3 + 1 \approx 1.095$, and the third point of intersection is $(\approx 0.457, 1.095)$.
- (c) Partitioning along the y -axis allows us to use just one integral, bounded above by $x = \cos y$ and below by $x = \sqrt[3]{y-1}$, so its area is

$$\int_0^{1.095} (\cos y - \sqrt[3]{y-1}) dy = \left[\sin y - \frac{3}{4}(y-1)^{4/3} \right]_0^{1.095} \approx 1.606.$$

55. (a) The three curves are shown below:

- (b) $2x + y = 3$ and $y = 1$ intersect at $x = 1$, which is the point $(1, 1)$. $y = 1$ intersects $y = \frac{1}{x^2+1}$ when $\frac{1}{x^2+1} = 1$, so when $x = 0$; this point is $(0, 1)$. Finally, $2x + y = 3$ intersects $y = \frac{1}{x^2+1}$ when $3 - 2x = \frac{1}{x^2+1}$. Clearing fractions and simplifying gives $2x^3 - 3x^2 + 2x - 2 = 0$. The only real root of this cubic is, using technology, $x \approx 1.317$. At that value, $y = 3 - 2 \cdot 1.317 \approx 0.366$, so the third point of intersection is $(\approx 1.317, 0.366)$.
- (c) Partitioning along the y -axis allows us to use just one integral, bounded above by $x = \frac{1}{2}(3 - y)$ and below by $x = \sqrt{\frac{1}{y} - 1}$, so its area is

$$\int_{0.366}^1 \left(\frac{1}{2}(3 - y) - \sqrt{\frac{1}{y} - 1} \right) dy \approx 0.295.$$

56. (a) The three curves are shown below:

(b) $x = 0$ and $y = \frac{5}{1+x^2}$ intersect at $(0, 5)$, while $x = 0$ and $x = \sqrt{y+2}$ intersect at $(0, -2)$. To find the third intersection point, we must solve the system $y = \frac{5}{1+x^2}$, $x = \sqrt{y+2}$; using technology, we get $(x, y) \approx (1.787, 1.193)$.

(c) Partition along the x -axis; then the second equation becomes $y = x^2 - 2$ and the area of the region is

$$\int_0^{1.787} \left(\frac{5}{1+x^2} - (x^2 - 2) \right) dx \approx 6.975.$$

57. (a) The three curves are shown below:

(b) $y = 1 - x^2$ and $y = 0$ intersect at $(-1, 0)$ and at $(1, 0)$; the point we are concerned with here is $(1, 0)$. The graph shows that $y = \sin^{-1} x$ and $y = 0$ intersect at $(0, 0)$. The third point of intersection is found by solving $1 - x^2 = \sin^{-1} x$; using technology we get $x \approx 0.599$, so that $y = 1 - 0.599^2 \approx 0.641$ and the third intersection point is $\approx (0.599, 0.641)$.

(c) Partitioning along the y -axis allows us to use a single integral, bounded above by $x = \sqrt{1 - y}$ and below by $x = \sin y$; the area of the region is then

$$\int_0^{0.641} (\sqrt{1 - y} - \sin y) dy \approx 0.325.$$

Challenge Problems

58. The region is shown below:

Since $(-y)^2 = y^2$ and $(-x)^2 - (-x)^4 = x^2 - x^4$, the graph is symmetric about both the x and y -axes. So we can compute its area by computing the portion of the area in the first quadrant and multiplying by 4. In the first quadrant, the equation of the curve is $y = \sqrt{x^2 - x^4} = x\sqrt{1 - x^2}$. Note also that if $x > 1$, then $x^2 - x^4 < 0$, so there are no points of the curve to the right of $x = 1$; therefore, the integral to compute the area will go from $x = 0$ to $x = 1$. Using the substitution $u = 1 - x^2$, $du = -2x dx$, then $x = 0$ corresponds to $u = 1$ and $x = 1$ to $u = 0$, so the total area is

$$4 \int_0^1 x \sqrt{1 - x^2} dx = -4 \cdot \frac{1}{2} \int_1^0 u^{1/2} du = -2 \left[\frac{2}{3} u^{3/2} \right]_1^0 = \boxed{\frac{4}{3}}.$$

59. The region (for $k = 1$) is shown below:

- (a) Partitioning along the x -axis, the upper edge of the region is $y = k$ and the lower edge is $y = \tan x$. The bounds of integration range from $x = 0$ to $x = \tan^{-1} k$, so the area is

$$A = \int_0^{\tan^{-1} k} (k - \tan x) dx = [kx + \ln \cos x]_0^{\tan^{-1} k} = k \tan^{-1} k + \ln \cos \tan^{-1} k.$$

Now, since x is positive, $\tan^{-1} k$ is in the first quadrant, so $\cos \tan^{-1} k = \frac{1}{\sqrt{1+k^2}}$, as can be seen by drawing a right triangle in the first quadrant whose tangent function is equal to k . Therefore

we get for the area

$$A = k \tan^{-1} k + \ln \frac{1}{\sqrt{1+k^2}} = \boxed{k \tan^{-1} k - \frac{1}{2} \ln(1+k^2)}.$$

(b) When $k = 1$,

$$A = 1 \cdot \tan^{-1} 1 - \frac{1}{2} \ln(1+1^2) = \boxed{\frac{\pi}{4} - \frac{1}{2} \ln 2}.$$

(c) Using the Chain Rule,

$$\begin{aligned} \frac{dA}{dt} &= \frac{dA}{dk} \cdot \frac{dk}{dt} \\ &= \left(\tan^{-1} k + \frac{k}{1+k^2} - \frac{1}{2(1+k^2)} \cdot 2k \right) \cdot \frac{dk}{dt} \\ &= \left(\tan^{-1} k + \frac{k}{1+k^2} - \frac{k}{1+k^2} \right) \cdot \frac{dk}{dt} \\ &= \tan^{-1} k \cdot \frac{dk}{dt}. \end{aligned}$$

When $\frac{dk}{dt} = \frac{1}{10}$ and $k = 1$, we get

$$\frac{dA}{dt} = \tan^{-1} 1 \cdot \frac{1}{10} = \boxed{\frac{\pi}{40} \text{ square units per second.}}$$

60. (a) If you reflect the first-quadrant shaded region across the x -axis, you get another region that is the same size as the first; the union of these two regions is a region whose area is A^* in the problem statement. The point where the line $y = -x$ meets the hyperbola in the fourth quadrant is the corner of this region; its coordinates are $(\cosh t, -\sinh t)$. So we get a triangle with vertices $(0, 0)$, $(\cosh t, \sinh t)$, and $(\cosh t, -\sinh t)$. This triangle has base (the vertical) $2 \sinh t$ and height $\cosh t$, so that its area is $\frac{1}{2} \cdot 2 \sinh t \cdot \cosh t = \sinh t \cosh t$. Since $\cosh^2 t - \sinh^2 t = 1$, we can rewrite this as $\cosh t \sqrt{\cosh^2 t - 1}$; since $x = \cosh t$, this becomes $x \sqrt{x^2 - 1}$. To compute the area of A^* , we must subtract from the area of the triangle the area under the hyperbola between $x = 1$ and $x = \cosh t$. We can compute this area by computing the area under the hyperbola in the first quadrant and doubling it, so (using u as a dummy variable), we get

$$2 \int_1^x \sinh u \, du = 2 \int_1^x \sqrt{\cosh^2 u - 1} \, du = 2 \int_1^x \sqrt{u^2 - 1} \, du.$$

Therefore

$$A^* = x \sqrt{x^2 - 1} - 2 \int_1^x \sqrt{u^2 - 1} \, du.$$

(b) Using the Fundamental Theorem of Calculus, we have

$$\begin{aligned} \frac{dA^*}{dx} &= \sqrt{x^2 - 1} + x \cdot \frac{1}{2}(x^2 - 1)^{-1/2} \cdot 2x - 2\sqrt{x^2 - 1} \\ &= -\sqrt{x^2 - 1} + \frac{x^2}{\sqrt{x^2 - 1}} \\ &= \frac{1}{\sqrt{x^2 - 1}}. \end{aligned}$$

(c) Since $\frac{d}{dx} \cosh^{-1} x = \frac{1}{\sqrt{x^2 - 1}}$, we see from part (b) that $A^* = \cosh^{-1} x + C$ for some constant C .

When $x = 1$, the area is empty, so that $A^* = 0$. Therefore we get $0 = \cosh^{-1} 1 + C = 0 + C$, so that $C = 0$. Substituting gives $A^* = \cosh^{-1} x$.

(d) Finally, since $x = \cosh t$ and $t \geq 0$, we get $t = \cosh^{-1} x = A^*$.

6.2: Volume of a Solid of Revolution: Disks and Washers

Concepts and Vocabulary

1. From the boxed formula in subsection 3 preceding Example 4, the formula is $V = \pi \int_a^b f(x)^2 dx$.
2. False. The cross section is indeed the region contained between two concentric circles. The radii of those circles are $f(u_i)$ and $g(u_i)$, so the area between them is the difference of their areas, or $\pi f(u_i)^2 - \pi g(u_i)^2 = \pi[f(u_i)^2 - g(u_i)^2]$, not $\pi[f(u_i) - g(u_i)]^2$.
3. False. From Problem 1, or the boxed formula in subsection 3 preceding Example 4, the volume is $V = \pi \int_a^b [f(x)^2 - g(x)^2] dx$.
4. False. First of all, the two curves intersect at $x = 0$ and $x = 2$, so the integral must go from 0 to 2. See the diagram:

Second, for a given value of x , the outer radius is $6 - x^2$ and the inner radius is $6 - 2x$, so the formula is

$$V = \pi \int_0^2 [(6 - x^2)^2 - (6 - 2x)^2] dx.$$

Skill Building

5. Using the disk method, the radius of each disk is $2\sqrt{x}$, so the volume is

$$V = \pi \int_1^4 (2\sqrt{x})^2 dx = 4\pi \int_1^4 x dx = 4\pi \left[\frac{1}{2}x^2 \right]_1^4 = \boxed{30\pi}.$$

6. Since we are revolving around the y -axis with the disk method, first solve the equation for x to get $x = y^{1/4}$. Then the radius of each disk is $y^{1/4}$, so the volume is

$$V = \pi \int_0^1 (y^{1/4})^2 dy = \pi \int_0^1 y^{1/2} dy = \pi \left[\frac{2}{3}y^{3/2} \right]_0^1 = \boxed{\frac{2}{3}\pi}.$$

7. Since we are revolving around the y -axis with the disk method, first solve the equation for x to get $x = \frac{1}{y}$. Then the radius of each disk is $\frac{1}{y}$, so the volume is

$$V = \pi \int_1^4 \left(\frac{1}{y} \right)^2 dy = \pi \int_1^4 \frac{1}{y^2} dy = \pi \left[-\frac{1}{y} \right]_1^4 = \pi \left(1 - \frac{1}{4} \right) = \boxed{\frac{3}{4}\pi}.$$

8. Since we are revolving around the y -axis with the disk method, first solve the equation for x to get $x = y^{3/2}$. Then the radius of each disk is $y^{3/2}$, so the volume is

$$V = \pi \int_1^4 (y^{3/2})^2 dy = \pi \int_1^4 y^3 dy = \pi \left[\frac{1}{4}y^4 \right]_1^4 = \boxed{\frac{255}{4}\pi}.$$

9. Using the washer method along the x -axis, each outer radius is $\sec x$ and the inner radius is 1, so that the volume is

$$V = \pi \int_{-1}^1 (\sec^2 x - 1^2) dx = \pi \int_{-1}^1 (\sec^2 x - 1) dx = \pi [\tan x - x]_{-1}^1 = \boxed{2\pi(\tan 1 - 1)}.$$

10. Since we are revolving around the y -axis, we solve $y = x^2$ for x , giving $x = \sqrt{y}$ (since $x \geq 0$). Then using the washer method, the volume is

$$V = \pi \int_0^4 (2^2 - (\sqrt{y})^2) dy = \pi \int_0^4 (4 - y) dy = \pi \left[4y - \frac{1}{2}y^2 \right]_0^4 = \boxed{8\pi}.$$

11. The region is shown below:

The radius of each disk is $2x^2$, so the volume is

$$V = \pi \int_0^1 (2x^2)^2 dx = \pi \int_0^1 4x^4 dx = \pi \left[\frac{4}{5}x^5 \right]_0^1 = \boxed{\frac{4}{5}\pi}.$$

12. The region is shown below:

The radius of each disk is $\sqrt{x}$, so the volume is

$$V = \pi \int_4^9 (\sqrt{x})^2 dx = \pi \int_4^9 x dx = \pi \left[\frac{1}{2}x^2 \right]_4^9 = \boxed{\frac{65}{2}\pi}.$$

13. The region is shown below:

The radius of each disk is e^{-x} , so the volume is

$$V = \pi \int_0^2 (e^{-x})^2 dx = \pi \int_0^2 e^{-2x} dx = \pi \left[-\frac{1}{2} e^{-2x} \right]_0^2 = \boxed{\frac{1}{2} \pi \left(1 - \frac{1}{e^4} \right)}.$$

14. The region is shown below:

The radius of each disk is e^x , so the volume is

$$V = \pi \int_{-1}^1 (e^x)^2 dx = \pi \int_{-1}^1 e^{2x} dx = \pi \left[\frac{1}{2} e^{2x} \right]_{-1}^1 = \boxed{\frac{1}{2} \pi \left(e^2 - \frac{1}{e^2} \right)}.$$

15. The region is shown below:

Solving for x gives $x = \sqrt{y}$ (since $x \geq 0$), so the radius of each disk is $\sqrt{y}$ and the volume is

$$V = \pi \int_1^4 (\sqrt{y})^2 dy = \pi \int_1^4 y dy = \pi \left[\frac{1}{2} y^2 \right]_1^4 = \boxed{\frac{15}{2} \pi}.$$

16. The region is shown below:

Solving for x gives $x = \frac{y^2}{4}$, so the radius of each disk is $\frac{y^2}{4}$ and the volume is

$$V = \pi \int_0^4 \left(\frac{y^2}{4} \right)^2 dy = \pi \int_0^4 \frac{1}{16} y^4 dy = \pi \left[\frac{1}{80} y^5 \right]_0^4 = \boxed{\frac{64}{5} \pi}.$$

17. The region is shown below:

The outer radius of each washer is 4 and the inner radius is x^2 , so the volume of the solid is

$$V = \pi \int_0^2 (4^2 - (x^2)^2) dx = \pi \int_0^2 (16 - x^4) dx = \pi \left[16x - \frac{1}{5} x^5 \right]_0^2 = \boxed{\frac{128}{5} \pi}.$$

18. The region is shown below:

The outer radius of each washer is 2 and the inner radius is $2x^2$, so the volume of the solid is

$$V = \pi \int_0^1 \left(2^2 - (2x^2)^2 \right) dx = \pi \int_0^1 (4 - 4x^4) dx = \pi \left[4x - \frac{4}{5}x^5 \right]_0^1 = \boxed{\frac{16}{5}\pi}.$$

19. The region is shown below:

The outer radius of each washer is 4 and the inner radius is $2\sqrt{x}$, so the volume of the solid is

$$V = \pi \int_0^4 \left(4^2 - (2\sqrt{x})^2 \right) dx = \pi \int_0^4 (16 - 4x) dx = \pi [16x - 2x^2]_0^4 = \boxed{32\pi}.$$

20. The region is shown below:

Solving $y = x^{2/3}$ for x gives $x = y^{3/2}$, so the outer radius of each washer when revolved around the y -axis is 8 and the inner radius is $y^{3/2}$. Therefore the volume is

$$V = \pi \int_0^4 \left(8^2 - (y^{3/2})^2 \right) dy = \pi \int_0^4 (64 - y^3) dy = \pi \left[64y - \frac{1}{4}y^4 \right]_0^4 = \boxed{192\pi}.$$

21. The region is shown below:

Solving $y = x^3$ for x gives $x = y^{1/3}$, so the outer radius of each washer when revolved around the y -axis is 2 and the inner radius is $y^{1/3}$. Therefore the volume is

$$V = \pi \int_0^8 \left(2^2 - \left(y^{1/3} \right)^2 \right) dy = \pi \int_0^8 \left(4 - y^{2/3} \right) dy = \pi \left[4y - \frac{3}{5} y^{5/3} \right]_0^8 = \boxed{\frac{64}{5} \pi}.$$

22. The region is shown below:

Solving $y = 2x^4$ for x gives $x = \left(\frac{y}{2}\right)^{1/4}$ (since $x \geq 0$), so the outer radius of each washer when revolved around the y -axis is 1 and the inner radius is $\left(\frac{y}{2}\right)^{1/4}$. Therefore the volume is

$$V = \pi \int_0^2 \left(1^2 - \left(\left(\frac{y}{2} \right)^{1/4} \right)^2 \right) dy = \pi \int_0^2 \left(1 - \frac{1}{\sqrt{2}} y^{1/2} \right) dy = \pi \left[y - \frac{\sqrt{2}}{3} y^{3/2} \right]_0^2 = \boxed{\frac{2}{3} \pi}.$$

23. The region is shown below:

Using the disk method, the radius of each disk around the x -axis is $\frac{1}{x}$, so the volume is

$$V = \pi \int_1^2 \left(\frac{1}{x} \right)^2 dx = \pi \int_1^2 \frac{1}{x^2} dx = \pi \left[-\frac{1}{x} \right]_1^2 = \boxed{\frac{\pi}{2}}.$$

24. This is the same region from Problem 23; it is pictured there. To rotate around the y -axis, we use the washer method. Solving $y = \frac{1}{x}$ for x gives $x = \frac{1}{y}$. Now, $x = \frac{1}{y}$ and $x = 2$ intersect when $y = \frac{1}{2}$. So from $y = 0$ to $y = \frac{1}{2}$, the outer radius is 2 while the inner radius is 1. From $y = \frac{1}{2}$ to $y = 1$ the outer

radius is $\frac{1}{y}$ and the inner radius is 1. Therefore the volume is

$$\begin{aligned}
 V &= \pi \int_0^{1/2} (2^2 - 1^2) dy + \pi \int_{1/2}^1 \left(\left(\frac{1}{y} \right)^2 - 1^2 \right) dy \\
 &= \pi \int_0^{1/2} 3 dy + \pi \int_{1/2}^1 \left(\frac{1}{y^2} - 1 \right) dy \\
 &= \pi [3y]_0^{1/2} + \pi \left[-\frac{1}{y} - y \right]_{1/2}^1 \\
 &= \boxed{2\pi}.
 \end{aligned}$$

25. The region is shown below:

Using the disk method to revolve about the y -axis, first solve $y = \sqrt{x}$ for x to get $x = y^2$. Then the radius of each disk is y^2 , so the volume is

$$V = \pi \int_0^9 (y^2)^2 dy = \pi \int_0^9 y^4 dy = \pi \left[\frac{1}{5} y^5 \right]_0^9 = \boxed{\frac{59049}{5} \pi}.$$

26. This is the same region from Problem 25; it is pictured there. To rotate around the x -axis, we use the disk method. The outer radius of each disk is 9, while the inner radius is $\sqrt{x}$. Therefore the volume is

$$V = \pi \int_0^{81} (9^2 - (\sqrt{x})^2) dx = \pi \int_0^{81} (81 - x) dx = \pi \left[81x - \frac{1}{2} x^2 \right]_0^{81} = \boxed{\frac{6561}{2} \pi}.$$

27. The region is shown below:

When revolving about the x -axis, we use the disk method. Note that the region lies both above and below the x -axis, so from $x = 0$ to $x = 2$, the radius will be $-(x-2)^3$, while from $x = 2$ to $x = 3$ it will

be $(x-2)^3$. However, since we square the radius, the minus sign will disappear in the computation — that is, $((x-2)^3)^2 = (-(x-2)^3)^2$. Therefore the volume is

$$V = \pi \int_0^3 ((x-2)^3)^2 dx = \pi \int_0^3 (x-2)^6 dx = \pi \left[\frac{1}{7}(x-2)^7 \right]_0^3 = \boxed{\frac{129}{7}\pi}.$$

28. This is the same region from Problem 27; it is pictured there. To rotate around the y -axis, first solve $y = (x-2)^3$ for x to get $x = 2 + y^{1/3}$. We use the disk method from $y = -8$ to $y = 0$, where the radius is $2 + y^{1/3}$. From $y = 0$ to $y = 1$ we use the washer method; the outer radius is 3 while the inner radius is $2 + y^{1/3}$. Therefore the volume is

$$\begin{aligned} V &= \pi \int_{-8}^0 (2 + y^{1/3})^2 dy + \pi \int_0^1 (3^2 - (2 + y^{1/3})^2) dy \\ &= \pi \int_{-8}^0 (y^{2/3} + 4y^{1/3} + 4) dy + \pi \int_0^1 (5 - 4y^{1/3} - y^{2/3}) dy \\ &= \pi \left[\frac{3}{5}y^{5/3} + 3y^{4/3} + 4y \right]_{-8}^0 + \pi \left[5y - 3y^{4/3} - \frac{3}{5}y^{5/3} \right]_0^1 \\ &= \boxed{\frac{23}{5}\pi}. \end{aligned}$$

29. The region is shown below:

When revolving about the y -axis, we first solve $y = (x+1)^2$ for x to get $x = \sqrt{y} - 1$. Using the disk method, the radius of each disk is $\sqrt{y} - 1$, so the volume is

$$V = \pi \int_1^{16} (\sqrt{y} - 1)^2 dy = \pi \int_1^{16} (y - 2y^{1/2} + 1) dy = \pi \left[\frac{1}{2}y^2 - \frac{4}{3}y^{3/2} + y \right]_1^{16} = \boxed{\frac{117}{2}\pi}.$$

30. The region is shown below:

To revolve around the x -axis, we use the washer method; each outer radius is 16 while the inner radius is $(x+1)^2$. Therefore the volume is

$$V = \pi \int_{-5}^0 \left(16^2 - ((x+1)^2)^2 \right) dx = \pi \int_{-5}^0 (256 - (x+1)^4) dx = \pi \left[256x - \frac{1}{5}(x+1)^5 \right]_{-5}^0 = \boxed{1075\pi}.$$

31. The region is shown below:

We use the disk method to revolve about the y -axis; the radius is $1 - y^4$. Therefore the volume is

$$V = \pi \int_{-1}^1 (1 - y^4)^2 dy = \pi \int_{-1}^1 (y^8 - 2y^4 + 1) dy = \pi \left[\frac{1}{9}y^9 - \frac{2}{5}y^5 + y \right]_{-1}^1 = \boxed{\frac{64}{45}\pi}.$$

32. The region is shown below:

We use the disk method to revolve about the x -axis; the radius is $1 - x^4$ (since $x^4 - 1 < 0$). Therefore the volume is

$$V = \pi \int_{-1}^1 (1 - x^4)^2 dx = \pi \int_{-1}^1 (1 - 2x^4 + x^8) dx = \pi \left[x - \frac{2}{5}x^5 + \frac{1}{9}x^9 \right]_{-1}^1 = \boxed{\frac{64}{45}\pi}.$$

(Note that this is the same region as in Problem 31, rotated 90° , so we would expect to get the same answer.)

33. The region is shown below:

We use the washer method to revolve about the x -axis. Each outer radius is $4x$, and each inner radius is x^3 , so the volume is

$$V = \pi \int_0^2 \left((4x)^2 - (x^3)^2 \right) dx = \pi \int_0^2 (16x^2 - x^6) dx = \pi \left[\frac{16}{3}x^3 - \frac{1}{7}x^7 \right]_0^2 = \boxed{\frac{512}{21}\pi}.$$

34. The region is shown below:

We use the washer method to revolve about the x -axis. Each outer radius is $2x + 1$, and each inner radius is x , so the volume is

$$V = \pi \int_0^3 \left((2x + 1)^2 - x^2 \right) dx = \pi \int_0^3 (3x^2 + 4x + 1) dx = \pi \left[x^3 + 2x^2 + x \right]_0^3 = \boxed{48\pi}.$$

35. The region is shown below:

We use the washer method to revolve about the x -axis. Each outer radius is e^x , and each inner radius is $1 - x$, so the volume is

$$\begin{aligned}
 V &= \pi \int_0^1 \left((e^x)^2 - (1 - x)^2 \right) dx \\
 &= \pi \int_0^1 (e^{2x} - 1 + 2x - x^2) dx \\
 &= \pi \left[\frac{1}{2} e^{2x} - x + x^2 - \frac{1}{3} x^3 \right]_0^1 \\
 &= \boxed{\left(\frac{1}{2} e^2 - \frac{5}{6} \right) \pi}.
 \end{aligned}$$

36. The region is shown below:

We use the washer method to revolve about the x -axis. Each outer radius is $\cos x$ and each inner radius is $\sin x$, so the volume is

$$\begin{aligned}
 V &= \pi \int_0^{\pi/4} \left((\cos x)^2 - (\sin x)^2 \right) dx \\
 &= \pi \int_0^{\pi/4} (\cos^2 x - \sin^2 x) dx \\
 &= \pi \int_0^{\pi/4} \cos 2x dx \\
 &= \pi \left[\frac{1}{2} \sin 2x \right]_0^{\pi/4} \\
 &= \boxed{\frac{\pi}{2}}.
 \end{aligned}$$

37. The region is shown below:

We use the disk method to revolve about the x -axis. Each radius is $\csc x$, so the volume is

$$V = \pi \int_{\pi/2}^{3\pi/4} (\csc x)^2 dx = \pi \int_{\pi/2}^{3\pi/4} \csc^2 x dx = \pi [-\cot x]_{\pi/2}^{3\pi/4} = \boxed{\pi}.$$

38. The region is shown below:

We use the disk method to revolve about the x -axis. Each radius is $\sec x$, so the volume is

$$V = \pi \int_0^{\pi/3} (\sec x)^2 dx = \pi \int_0^{\pi/3} \sec^2 x dx = \pi [\tan x]_0^{\pi/3} = \boxed{\pi\sqrt{3}}.$$

39. The region is shown below, with the line of revolution shown as a dashed line:

To revolve about $y = -1$, we use the washer method. Each outer radius is $e^x - (-1) = e^x + 1$, and each inner radius is $0 - (-1) = 1$. Therefore the volume is

$$V = \pi \int_0^2 \left((e^x + 1)^2 - 1^2 \right) dx = \pi \int_0^2 (e^{2x} + 2e^x) dx = \pi \left[\frac{1}{2}e^{2x} + 2e^x \right]_0^2 = \boxed{\pi \left(\frac{1}{2}e^4 + 2e^2 - \frac{5}{2} \right)}.$$

40. The region is shown below, with the line of revolution shown as a dashed line:

To revolve about $y = 4$, we use the washer method. Each outer radius is $4 - 0 = 4$, and each inner radius is $4 - \frac{1}{x}$. Therefore the volume is

$$V = \pi \int_1^4 \left(4^2 - \left(4 - \frac{1}{x} \right)^2 \right) dx = \pi \int_1^4 \left(\frac{8}{x} - \frac{1}{x^2} \right) dx = \pi \left[8 \ln x + \frac{1}{x} \right]_1^4 = \boxed{\left(16 \ln 2 - \frac{3}{4} \right) \pi}.$$

41. The region is shown below, with the line of revolution shown as a dashed line:

To revolve about $x = 1$, we first solve $y = x^2$ for x to get $x = \sqrt{y}$. Using the disk method, each radius is $1 - \sqrt{y}$. Therefore the volume is

$$V = \pi \int_0^1 (1 - \sqrt{y})^2 dy = \pi \int_0^1 \left(1 - 2y^{1/2} + y \right) dy = \pi \left[y - \frac{4}{3}y^{3/2} + \frac{1}{2}y^2 \right]_0^1 = \boxed{\frac{\pi}{6}}.$$

42. The region is shown below, with the line of revolution shown as a dashed line:

To revolve about $x = -1$, we first solve $y = x^3$ for x to get $x = y^{1/3}$. Using the washer method, the outer radius is $y^{1/3} - (-1) = y^{1/3} + 1$, while the inner radius is $0 - (-1) = 1$. Therefore the volume is

$$V = \pi \int_0^1 \left((y^{1/3} + 1)^2 - 1^2 \right) dy = \pi \int_0^1 (y^{2/3} + 2y^{1/3}) dy = \pi \left[\frac{3}{5}y^{5/3} + \frac{3}{2}y^{4/3} \right]_0^1 = \boxed{\frac{21}{10}\pi}.$$

43. The region is shown below, with the line of revolution shown as a dashed line:

To revolve about $x = -4$, we first solve $y = \sqrt{x}$ for x to get $x = y^2$. Using the washer method, the outer radius is $4 - (-4) = 8$ and the inner radius is $y^2 - (-4) = y^2 + 4$. Therefore the volume is

$$V = \pi \int_0^2 (8^2 - (y^2 + 4)^2) dy = \pi \int_0^2 (48 - 8y^2 - y^4) dy = \pi \left[48y - \frac{8}{3}y^3 - \frac{1}{5}y^5 \right]_0^2 = \boxed{\frac{1024}{15}\pi}.$$

44. The region is shown below, with the line of revolution shown as a dashed line:

To revolve about $x = 4$, we first solve $y = \frac{1}{\sqrt{x}}$ for x to get $x = \frac{1}{y^2}$. For $0 \leq y \leq \frac{1}{2}$, we can use the disk method with radius $4 - 1 = 3$. For $\frac{1}{2} \leq y \leq 1$, we use the washer method, with outer radius $4 - 1 = 3$ and inner radius $4 - \frac{1}{y^2}$. Therefore the volume is

$$\begin{aligned} V &= \pi \int_0^{1/2} 3^2 dy + \pi \int_{1/2}^1 \left(3^2 - \left(4 - \frac{1}{y^2} \right)^2 \right) dy \\ &= \pi \int_0^{1/2} 9 dy + \pi \int_{1/2}^1 \left(-7 + \frac{8}{y^2} - \frac{1}{y^4} \right) dy \\ &= \pi [9y]_0^{1/2} + \pi \left[-7y - \frac{8}{y} + \frac{1}{3y^3} \right]_{1/2}^1 \\ &= \boxed{\frac{20}{3}\pi}. \end{aligned}$$

45. The region is shown below, with the line of revolution shown as a dashed line:

To revolve about $y = 4$, we use the washer method. The outer radius is $4 - 0 = 4$, while the inner radius is $4 - \frac{1}{x^2}$. Therefore the volume is

$$V = \pi \int_1^4 \left(4^2 - \left(4 - \frac{1}{x^2} \right)^2 \right) dx = \pi \int_1^4 \left(\frac{8}{x^2} - \frac{1}{x^4} \right) dx = \pi \left[-\frac{8}{x} + \frac{1}{3x^3} \right]_1^4 = \boxed{\frac{363}{64}\pi}.$$

46. The region is shown below, with the line of revolution shown as a dashed line:

To revolve about $y = -4$, we use the washer method. The outer radius is $\sqrt{x} - (-4) = \sqrt{x} + 4$, while the inner radius is $0 - (-4) = 4$. Therefore the volume is

$$V = \pi \int_0^4 \left((\sqrt{x} + 4)^2 - 4^2 \right) dx = \pi \int_0^4 (8\sqrt{x} + x) dx = \pi \left[\frac{16}{3}x^{3/2} + \frac{1}{2}x^2 \right]_0^4 = \boxed{\frac{152}{3}\pi}.$$

Applications and Extensions

47. The graph of $y = kx - x^2$ intersects the x -axis at $x = 0$ and again at $x = k$. A graph of $kx - x^2$, with the region in question shaded, is below:

- (a) When the region is revolved around the x -axis, we use the disk method; the radius is $kx - x^2$, so the volume is

$$V_x = \pi \int_0^k (kx - x^2)^2 dx = \pi \int_0^k (k^2x^2 - 2kx^3 + x^4) dx = \pi \left[\frac{1}{3}k^2x^3 - \frac{1}{2}kx^4 + \frac{1}{5}x^5 \right]_0^k = \boxed{\frac{1}{30}\pi k^5}.$$

- (b) When the region is revolved around the y -axis, we use the washer method. First solve $y = kx - x^2$ for x , giving

$$x = \frac{1}{2}(k \pm \sqrt{k^2 - 4y}).$$

These two roots correspond to the portions of the curve to the left and to the right, respectively, of $x = \frac{k}{2}$. Therefore the inner radius is given by the first root and the outer radius by the second root, so the volume is

$$\begin{aligned} V_y &= \pi \int_0^{k^2/4} \left(\left(\frac{1}{2}(k + \sqrt{k^2 - 4y}) \right)^2 - \left(\frac{1}{2}(k - \sqrt{k^2 - 4y}) \right)^2 \right) dy \\ &= \frac{\pi}{4} \int_0^{k^2/4} \left(k^2 + 2k\sqrt{k^2 - 4y} + k^2 - 4y - (k^2 - 2k\sqrt{k^2 - 4y} + k^2 - 4y) \right) dy \\ &= \frac{\pi}{4} \int_0^{k^2/4} 4k(k^2 - 4y)^{1/2} dy \\ &= \frac{\pi}{4} \left[-\frac{2}{3}k(k^2 - 4y)^{3/2} \right]_0^{k^2/4} \\ &= \boxed{\frac{1}{6}\pi k^4}. \end{aligned}$$

- (c) The two volumes are equal when $\frac{1}{30}\pi k^5 = \frac{1}{6}\pi k^4$. Since $k > 0$, dividing through by πk^4 gives $\frac{1}{30}k = \frac{1}{6}$, so that $\boxed{k = 5}$.
48. (a) The graphs of $y = 2x + b$ and $y^2 = 4x$ intersect when $(2x + b)^2 = 4x$. Expanding this equation gives $4x^2 + (4b - 4)x + b^2 = 0$; this quadratic equation has roots

$$x = \frac{4 - 4b \pm \sqrt{(4b - 4)^2 - 16b^2}}{8} = \frac{1}{2}(1 - b \pm \sqrt{1 - 2b}).$$

So there are two distinct points of intersection when the roots of this quadratic equation are real and distinct, which occurs when $1 - 2b > 0$, or when $b < \frac{1}{2}$.

(b) When $b = -4$, the region is shown below:

To find the area of this region, we partition along the y -axis. Solving these two equations for x gives $x = \frac{y^2}{4}$ and $x = \frac{y+4}{2} = \frac{1}{2}y + 2$, so the area of the region is

$$\int_{-2}^4 \left(\frac{1}{2}y + 2 - \frac{y^2}{4} \right) dy = \left[\frac{1}{4}y^2 + 2y - \frac{1}{12}y^3 \right]_{-2}^4 = \boxed{9}.$$

(c) When $b = 0$, the region is shown below:

Revolving this region about the x -axis, we use the washer method; the outer radius is $\sqrt{4x}$ and the inner radius is $2x$, so that the volume is

$$V = \pi \int_0^1 \left((\sqrt{4x})^2 - (2x)^2 \right) dx = \pi \int_0^1 (4x - 4x^2) dx = \pi \left[2x^2 - \frac{4}{3}x^3 \right]_0^1 = \boxed{\frac{2}{3}\pi}.$$

49. The region is shown below, with the line of revolution shown as a dashed line:

Revolving about the line $y = 1$, we use the washer method. The outer radius is $1 - 0 = 1$, and the inner radius is $1 - \cos x$, so the volume is

$$\begin{aligned}
 V &= \pi \int_0^{\pi/2} (1^2 - (1 - \cos x)^2) dx = \pi \int_0^{\pi/2} (2 \cos x - \cos^2 x) dx \\
 &= \pi \int_0^{\pi/2} \left(2 \cos x - \left(\frac{1 + \cos 2x}{2} \right) \right) dx \\
 &= \pi \int_0^{\pi/2} \left(2 \cos x - \frac{1}{2} - \frac{1}{2} \cos 2x \right) dx \\
 &= \pi \left[2 \sin x - \frac{1}{2}x - \frac{1}{4} \sin 2x \right]_0^{\pi/2} \\
 &= \pi \left(2 - \frac{\pi}{4} \right) = \boxed{2\pi - \frac{\pi^2}{4}}.
 \end{aligned}$$

50. A plot of this region is identical to the plot for Problem 49, except that the line of rotation is $y = -1$ instead of $y = 1$. Again we use the washer method; this time the outer radius is $\cos x - (-1) = 1 + \cos x$ and the inner radius is $0 - (-1) = 1$. Therefore the volume is

$$\begin{aligned}
 V &= \pi \int_0^{\pi/2} ((1 + \cos x)^2 - 1^2) dx = \pi \int_0^{\pi/2} (2 \cos x + \cos^2 x) dx \\
 &= \pi \int_0^{\pi/2} \left(2 \cos x + \frac{1 + \cos 2x}{2} \right) dx \\
 &= \pi \int_0^{\pi/2} \left(2 \cos x + \frac{1}{2} + \frac{1}{2} \cos 2x \right) dx \\
 &= \pi \left[2 \sin x + \frac{1}{2}x + \frac{1}{4} \sin 2x \right]_0^{\pi/2} \\
 &= \pi \left(2 + \frac{\pi}{4} \right) = \boxed{2\pi + \frac{\pi^2}{4}}.
 \end{aligned}$$

Challenge Problems

51. $P(x)$ together with the line $y = e^{-b^2}$ is below:

- (a) No matter what k is, $P(0) = 0$, so that $(0, 0)$ is always on the graph. Evaluating at b , we also have $P(b) = kb^2 = e^{-b^2}$, so that $k = \frac{1}{b^2}e^{-b^2}$. Therefore $P(x) = \frac{1}{b^2}e^{-b^2}x^2$.
- (b) The line $y = e^{-b^2}$ intersects the curve at $x = b$. Also, for $0 \leq x \leq b$, we have $\frac{x^2}{b^2} \leq 1$ and so $P(x) = \frac{x^2}{b^2}e^{-b^2} \leq e^{-b^2}$, so that the region is bounded above by $y = e^{-b^2}$ and below by $P(x)$. The

left edge of the region is at $x = 0$ and the right edge is at $x = b$. Using the shell method, we get for the volume

$$\begin{aligned} V &= 2\pi \int_0^b x \left(e^{-b^2} - \frac{1}{b^2} e^{-b^2} x^2 \right) dx = 2\pi e^{-b^2} \int_0^b \left(x - \frac{1}{b^2} x^3 \right) dx \\ &= 2\pi e^{-b^2} \left[\frac{1}{2} x^2 - \frac{1}{4b^2} x^4 \right]_0^b = \boxed{\frac{1}{2} \pi \frac{b^2}{e^{b^2}}}. \end{aligned}$$

- (c) Regarding the volume V as a function of b , it reaches its maximum either at a critical point or at $b = 0$, which is the left end of its interval. However, we need not consider $b = 0$ since we are assuming $b > 0$. Now,

$$V'(b) = \pi b e^{-b^2} + \frac{1}{2} \pi b^2 e^{-b^2} \cdot (-2b) = \pi e^{-b^2} (b - b^3),$$

so the only critical points are when $b - b^3 = 0$, so for $b = 0$ or $b = \pm 1$. Since we are assuming $b > 0$, the only relevant critical point is $b = 1$. Then

$$V(1) = \frac{1}{2} \pi \cdot 1^2 e^{-1^2} = \frac{1}{2} \pi e^{-1/2} \approx 0.578.$$

Since $\lim_{b \rightarrow \infty} V(b) = 0$ as the exponential term dominates, it follows that $\boxed{b = 1}$ is in fact a global maximum.

52. Since $\cosh x \geq 1$ for all values of x , it follows that

$$a \cosh \left(\frac{x}{a} \right) + b - a \geq a + b - a = b,$$

so assuming $b > 0$, we see that $y \geq 0$ for any x . Then using the disk method, the radius of each disk is $a \cosh \left(\frac{x}{a} \right) + b - a$, so the volume is

$$\begin{aligned} V &= \pi \int_0^1 \left(a \cosh \left(\frac{x}{a} \right) + b - a \right)^2 dx \\ &= \pi \int_0^1 \left(a^2 \cosh^2 \left(\frac{x}{a} \right) + 2(b-a)a \cosh \left(\frac{x}{a} \right) + (b-a)^2 \right) dx \\ &= \pi \int_0^1 \left(a^2 \left(\frac{1 + \cosh 2 \left(\frac{x}{a} \right)}{2} \right) + 2(b-a)a \cosh \left(\frac{x}{a} \right) + (b-a)^2 \right) dx \\ &= \pi \int_0^1 \left(\frac{a^2}{2} \cosh 2 \left(\frac{x}{a} \right) + \frac{a^2}{2} + 2(b-a)a \cosh \left(\frac{x}{a} \right) + (b-a)^2 \right) dx \\ &= \pi \left[\frac{a^3}{4} \sinh 2 \left(\frac{x}{a} \right) + \frac{a^2}{2} x + 2(b-a)a^2 \sinh \left(\frac{x}{a} \right) + (b-a)^2 x \right]_0^1 \\ &= \boxed{\pi \left(\frac{a^3}{4} \sinh \frac{2}{a} + \frac{a^2}{2} + 2(b-a)a^2 \sinh \frac{1}{a} + (b-a)^2 \right)}. \end{aligned}$$

6.3: Volume of a Solid of Revolution: Cylindrical Shells

Concepts and Vocabulary

- False. When using the method of shells, the integration occurs along the axis perpendicular to the axis of revolution.
- False. It is given by $\pi R^2 h - \pi r^2 h = \pi(R^2 - r^2)h$.

3. False. Sections 6.2 and 6.3 present methods for determining such volumes under rotation about either the x or y -axis.
4. True. See the discussion in the text. The x represents the radius of each cylinder, $f(x)$ represents the height, and dx represents the thickness.

Skill Building

5. The region is shown below:

When revolving about the y -axis, using the shell method, each cylinder has a radius of x and a height of $x^2 + 1$, so the volume is

$$V = 2\pi \int_0^1 x(x^2 + 1) dx = 2\pi \int_0^1 (x^3 + x) dx = 2\pi \left[\frac{1}{4}x^4 + \frac{1}{2}x^2 \right]_0^1 = \boxed{\frac{3}{2}\pi}.$$

6. The region is shown below:

When revolving about the y -axis using the shell method, each cylinder has a radius of x and a height of $x^2 - x^3$, so the volume is

$$V = 2\pi \int_0^1 x(x^2 - x^3) dx = 2\pi \int_0^1 (x^3 - x^4) dx = 2\pi \left[\frac{1}{4}x^4 - \frac{1}{5}x^5 \right]_0^1 = \boxed{\frac{1}{10}\pi}.$$

7. The region is shown below:

When revolving about the y -axis using the shell method, each cylinder has a radius of x and a height of $\sqrt{x} - x^2$, so the volume is

$$V = 2\pi \int_0^1 x (\sqrt{x} - x^2) dx = 2\pi \int_0^1 (x^{3/2} - x^3) dx = 2\pi \left[\frac{2}{5} x^{5/2} - \frac{1}{4} x^4 \right]_0^1 = \boxed{\frac{3}{10}\pi}.$$

8. The region is shown below:

When revolving about the y -axis using the shell method, each cylinder has a radius of x and a height of $\frac{1}{x}$, so the volume is

$$V = 2\pi \int_1^4 x \cdot \frac{1}{x} dx = 2\pi \int_1^4 1 dx = \boxed{6\pi}.$$

9. The region is shown below:

When revolving about the x -axis using the shell method, we first solve $y = x^3$ for x , giving $x = y^{1/3}$. Then each cylinder has a radius of y and a height of $y^{1/3}$, so the volume is

$$V = 2\pi \int_0^8 y \cdot y^{1/3} dy = 2\pi \int_0^8 y^{4/3} dy = 2\pi \left[\frac{3}{7} y^{7/3} \right]_0^8 = \boxed{\frac{768}{7}\pi}.$$

10. The region is shown below:

When revolving about the x -axis using the shell method, we first solve $y = \sqrt{x}$ for x , giving $x = y^2$. Then each cylinder has a radius of y and a height of y^2 , so the volume is

$$V = 2\pi \int_0^2 y \cdot y^2 dy = 2\pi \int_0^2 y^3 dy = 2\pi \left[\frac{1}{4} y^4 \right]_0^2 = \boxed{8\pi}.$$

11. The region is shown below:

When revolving about the x -axis using the shell method, each cylinder has a radius of y and a height of $\sqrt{y}$, so the volume is

$$V = 2\pi \int_0^1 y \cdot \sqrt{y} dy = 2\pi \int_0^1 y^{3/2} dy = 2\pi \left[\frac{2}{5} y^{5/2} \right]_0^1 = \boxed{\frac{4}{5}\pi}.$$

12. The region is shown below:

When revolving about the x -axis using the shell method, each cylinder has a radius of y and a height of $4\sqrt{y}$, so the volume is

$$V = 2\pi \int_0^4 y \cdot 4\sqrt{y} \, dy = 8\pi \int_0^4 y^{3/2} \, dy = 8\pi \left[\frac{2}{5} y^{5/2} \right]_0^4 = \boxed{\frac{512}{5}\pi}.$$

13. The region is shown below:

When revolving about the x -axis using the shell method, we first solve the two equations for x , giving $x = y$ and $x = \sqrt{y}$. Then each shell has a radius of y and a height of $\sqrt{y} - y$, so that the volume is

$$V = 2\pi \int_0^1 y (\sqrt{y} - y) \, dy = 2\pi \int_0^1 (y^{3/2} - y^2) \, dy = 2\pi \left[\frac{2}{5} y^{5/2} - \frac{1}{3} y^3 \right]_0^1 = \boxed{\frac{2}{15}\pi}.$$

14. The region is shown below:

When revolving about the x -axis using the shell method, we first solve the two equations for x , giving $x = y$ and $x = y^{1/3}$. Then each shell has a radius of y and a height of $y^{1/3} - y$, so that the volume is

$$V = 2\pi \int_0^1 y (y^{1/3} - y) dy = 2\pi \int_0^1 (y^{4/3} - y^2) dy = 2\pi \left[\frac{3}{7} y^{7/3} - \frac{1}{3} y^3 \right]_0^1 = \boxed{\frac{4}{21} \pi}.$$

15. The region is shown below:

When revolving about the y -axis using the shell method, each shell has a radius of x and a height of e^{-x^2} , so that the volume is

$$V = 2\pi \int_0^2 x e^{-x^2} dx.$$

Now use the substitution $u = -x^2$, so that $du = -2x dx$. Then $x = 0$ corresponds to $u = 0$, and $x = 2$ to $u = -4$, so we get

$$V = -\frac{1}{2} \cdot 2\pi \int_0^{-4} e^u du = -\pi [e^u]_0^{-4} = \boxed{\pi \left(1 - \frac{1}{e^4} \right)}.$$

16. The region is shown below:

When revolving about the y -axis using the shell method, each shell has a radius of x and a height of $x^3 + x$, so that the volume is

$$V = 2\pi \int_0^1 x (x^3 + x) dx = 2\pi \int_0^1 (x^4 + x^2) dx = 2\pi \left[\frac{1}{5} x^5 + \frac{1}{3} x^3 \right]_0^1 = \boxed{\frac{16}{15} \pi}.$$

17. The region is shown below:

When revolving about $x = 4$ using the shell method, each shell has a radius of $4 - x$ (the distance from x to 4) and a height of $4x - x^2 - x^2 = 4x - 2x^2$. Therefore the volume is

$$V = 2\pi \int_0^2 (4 - x)(4x - 2x^2) dx = 2\pi \int_0^2 (2x^3 - 12x^2 + 16x) dx = 2\pi \left[\frac{1}{2}x^4 - 4x^3 + 8x^2 \right]_0^2 = \boxed{16\pi}.$$

18. The region is shown below:

When revolving about $x = 3$ using the shell method, each shell has a radius of $3 - x$ (the distance from x to 3) and a height of $4x - x^2 - x^2 = 4x - 2x^2$. Therefore the volume is

$$V = 2\pi \int_0^2 (3 - x)(4x - 2x^2) dx = 2\pi \int_0^2 (2x^3 - 10x^2 + 12x) dx = 2\pi \left[\frac{1}{2}x^4 - \frac{10}{3}x^3 + 6x^2 \right]_0^2 = \boxed{\frac{32}{3}\pi}.$$

19. The region is shown below:

When revolving about $x = 1$ using the shell method, each shell has a radius of $x - 1$ (the distance from x to 1) and a height of x^2 . Therefore the volume is

$$V = 2\pi \int_1^2 (x-1)x^2 dx = 2\pi \int_1^2 (x^3 - x^2) dx = 2\pi \left[\frac{1}{4}x^4 - \frac{1}{3}x^3 \right]_1^2 = \boxed{\frac{17}{6}\pi}.$$

20. The region is shown below:

When revolving about $x = -2$ using the shell method, each shell has a radius of $x - (-2) = x + 2$ (the distance from x to -2) and a height of x^2 . Therefore the volume is

$$V = 2\pi \int_1^2 (x+2)x^2 dx = 2\pi \int_1^2 (x^3 + 2x^2) dx = 2\pi \left[\frac{1}{4}x^4 + \frac{2}{3}x^3 \right]_1^2 = \boxed{\frac{43}{6}\pi}.$$

21. The region is shown below:

When revolving about $y = -1$ using the shell method, each shell has a radius of $y - (-1) = y + 1$ (the distance from y to -1) and a height of $y - y^2$. Therefore the volume is

$$V = 2\pi \int_0^1 (y+1)(y-y^2) dy = 2\pi \int_0^1 (-y^3 + y) dy = 2\pi \left[-\frac{1}{4}y^4 + \frac{1}{2}y^2 \right]_0^1 = \boxed{\frac{\pi}{2}}.$$

22. The region is shown below:

When revolving about $y = 1$ using the shell method, each shell has a radius of $1 - y$ (the distance from y to 1) and a height of $y - y^2$. Therefore the volume is

$$V = 2\pi \int_0^1 (1 - y)(y - y^2) dy = 2\pi \int_0^1 (y^3 - 2y^2 + y) dy = 2\pi \left[\frac{1}{4}y^4 - \frac{2}{3}y^3 + \frac{1}{2}y^2 \right]_0^1 = \boxed{\frac{\pi}{6}}.$$

23. (a) To rotate about the x -axis, use the disk method; the radius of each disk is $2x^2 - x^3$. Therefore the volume is

$$V = \pi \int_0^2 (2x^2 - x^3)^2 dx = \pi \int_0^2 (4x^4 - 4x^5 + x^6) dx = \pi \left[\frac{4}{5}x^5 - \frac{2}{3}x^6 + \frac{1}{7}x^7 \right]_0^2 = \boxed{\frac{128}{105}\pi}.$$

(b) To rotate about the y -axis, use the shell method; the radius of each shell is x and its height is $2x^2 - x^3$, so the volume is

$$V = 2\pi \int_0^2 x(2x^2 - x^3) dx = 2\pi \int_0^2 (2x^3 - x^4) dx = 2\pi \left[\frac{1}{2}x^4 - \frac{1}{5}x^5 \right]_0^2 = \boxed{\frac{16}{5}\pi}.$$

(c) In each case, we chose to integrate by partitioning along the x -axis, since partitioning along the y -axis would entail solving $y = 2x^2 - x^3$ for x and then using one solution as the lower bound and the other as the upper bound.

24. (a) To rotate about the x -axis, use the washer method; the outer radius of each disk is $-x^2 + 9$ and the inner radius is $2x + 1$. Therefore the volume is

$$\begin{aligned} V &= \pi \int_0^2 ((-x^2 + 9)^2 - (2x + 1)^2) dx \\ &= \pi \int_0^2 (x^4 - 22x^2 - 4x + 80) dx \\ &= \pi \left[\frac{1}{5}x^5 - \frac{22}{3}x^3 - 2x^2 + 80x \right]_0^2 \\ &= \boxed{\frac{1496}{15}\pi}. \end{aligned}$$

- (b) To rotate about the y -axis, use the shell method. The radius of each shell is x , and its height is $-x^2 + 9 - (2x + 1) = -x^2 - 2x + 8$. Therefore the volume is

$$V = 2\pi \int_0^2 x(-x^2 - 2x + 8) dx = 2\pi \int_0^2 (-x^3 - 2x^2 + 8x) dx = 2\pi \left[-\frac{1}{4}x^4 - \frac{2}{3}x^3 + 4x^2 \right]_0^2 = \boxed{\frac{40}{3}\pi}.$$

- (c) In each case, we chose to integrate by partitioning along the x -axis, since partitioning along the y -axis would entail splitting the integral into two separate integrals, one from $y = 0$ to $y = 5$ and the other from $y = 5$ to $y = 9$.

25. (a) To rotate about the x -axis, use the disk method; the radius of each disk is $x^2 + 1$, so the volume is

$$V = \pi \int_0^2 (x^2 + 1)^2 dx = \pi \int_0^2 (x^4 + 2x^2 + 1) dx = \pi \left[\frac{1}{5}x^5 + \frac{2}{3}x^3 + x \right]_0^2 = \boxed{\frac{206}{15}\pi}.$$

- (b) To rotate about the y -axis, use the shell method; the radius of each shell is x and its height is $x^2 + 1$, so the volume is

$$V = 2\pi \int_0^2 x(x^2 + 1) dx = 2\pi \int_0^2 (x^3 + x) dx = 2\pi \left[\frac{1}{4}x^4 + \frac{1}{2}x^2 \right]_0^2 = \boxed{12\pi}.$$

- (c) In each case, we chose to integrate by partitioning along the x -axis, since partitioning along the y -axis would entail splitting the integral into two separate integrals, one from $y = 0$ to $y = 1$ and the other from $y = 1$ to $y = 5$.

26. (a) To rotate about the x -axis, use the disk method; the radius of each disk is $4x - x^2$, so the volume is

$$V = \pi \int_0^4 (4x - x^2)^2 dx = \pi \int_0^4 (16x^2 - 8x^3 + x^4) dx = \pi \left[\frac{16}{3}x^3 - 2x^4 + \frac{1}{5}x^5 \right]_0^4 = \boxed{\frac{512}{15}\pi}.$$

- (b) To rotate about the y -axis, use the shell method; the radius of each shell is x and its height is $4x - x^2$, so the volume is

$$V = 2\pi \int_0^4 x(4x - x^2) dx = 2\pi \int_0^4 (4x^2 - x^3) dx = 2\pi \left[\frac{4}{3}x^3 - \frac{1}{4}x^4 \right]_0^4 = \boxed{\frac{128}{3}\pi}.$$

- (c) In each case, we chose to integrate by partitioning along the x -axis, since partitioning along the y -axis would entail solving $y = 4x - x^2$ for x and then using one solution as the lower bound and the other as the upper bound.

27. The region is shown below:

This could be done using shells along the y -axis or washers along the x -axis. Since $y = x^{1/3}$ becomes $x = y^3$, which is somewhat simpler, we choose the shell method. Then the radius of each shell is y and its height is y^3 , so the volume is

$$V = 2\pi \int_0^2 y \cdot y^3 dy = 2\pi \int_0^2 y^4 dy = 2\pi \left[\frac{1}{5} y^5 \right]_0^2 = \boxed{\frac{64}{5}\pi}.$$

28. The region is shown below:

If we chose disks/washers along the y -axis, we would have to solve the equation for x , and we would have to split the integral up into two separate integrals. So use shells along the x -axis. The radius of each shell is x , and the height is $\sqrt{x} + x$, so the volume is

$$V = 2\pi \int_1^4 x(\sqrt{x} + x) dx = 2\pi \int_1^4 (x^{3/2} + x^2) dx = 2\pi \left[\frac{2}{5} x^{5/2} + \frac{1}{3} x^3 \right]_1^4 = \boxed{\frac{334}{5}\pi}.$$

29. The region is shown below:

Either disks/washers along the y -axis or shells along the x -axis could be used. Since we are given y in terms of x , we choose shells. The radius of each shell is x , and the height is $x - x^3$, so the volume is

$$V = 2\pi \int_0^1 x(x - x^3) dx = 2\pi \int_0^1 (x^2 - x^4) dx = 2\pi \left[\frac{1}{3} x^3 - \frac{1}{5} x^5 \right]_0^1 = \boxed{\frac{4}{15}\pi}.$$

30. The region is shown below:

Either disks/washers along the x -axis or shells along the y -axis could be used. Since we are given y in terms of x , we choose disks/washers. The outer radius of each washer is x^2 and the inner radius is x^3 , so the volume is

$$V = \pi \int_0^1 \left((x^2)^2 - (x^3)^2 \right) dx = \pi \int_0^1 (x^4 - x^6) dx = \pi \left[\frac{1}{5}x^5 - \frac{1}{7}x^7 \right]_0^1 = \boxed{\frac{2}{35}\pi}.$$

31. The region is shown below:

If we use disks along the y -axis, we will need two separate integrals, since the outer radius changes equations at $y = 27$. So use shells along the x -axis. The radius of each shell is x , and the height is $30 - x - 3x^2$, so the volume is

$$V = 2\pi \int_1^3 x (30 - x - 3x^2) dx = 2\pi \int_1^3 (30x - x^2 - 3x^3) dx = 2\pi \left[15x^2 - \frac{1}{3}x^3 - \frac{3}{4}x^4 \right]_1^3 = \boxed{\frac{308}{3}\pi}.$$

32. This is the same region as in Problem 31, but revolved about the x -axis. A similar argument applies: if we use shells along the y -axis, we would require two separate integrals, so we use the washer method along the x -axis. The outer radius of each washer is $30 - x$ and the inner radius is $3x^2$, so the volume is

$$\begin{aligned} V &= \pi \int_1^3 \left((30 - x)^2 - (3x^2)^2 \right) dx \\ &= \pi \int_1^3 (-9x^4 + x^2 - 60x + 900) dx \\ &= \pi \left[-\frac{9}{5}x^5 + \frac{1}{3}x^3 - 30x^2 + 900x \right]_1^3 \\ &= \boxed{\frac{16996}{15}\pi}. \end{aligned}$$

33. The region is shown below:

If we use shells along the y -axis, we will need two separate integrals, since the outer radius changes equations at $y = 4$. So use washers along the x -axis. The outer radius is $8 - x^2$ and the inner radius is x^2 , so the volume is

$$V = \pi \int_1^2 \left((8 - x^2)^2 - (x^2)^2 \right) dx = \pi \int_1^2 (64 - 16x^2) dx = \pi \left[64x - \frac{16}{3}x^3 \right]_1^2 = \boxed{\frac{80}{3}\pi}.$$

34. This is the same region as in Problem 33, but revolved about the y -axis. A similar argument applies: if we use disks along the y -axis, we will need two separate integrals, since the outer radius changes equations at $y = 4$. So use shells along the x -axis. The radius of each shell is x , and the height is $8 - x^2 - x^2 = 8 - 2x^2$, so the volume is

$$V = 2\pi \int_1^2 x (8 - 2x^2) dx = 2\pi \int_1^2 (8x - 2x^3) dx = 2\pi \left[4x^2 - \frac{1}{2}x^4 \right]_1^2 = \boxed{9\pi}.$$

35. The region is shown below:

This can be done either using washers along the y -axis or shells along the x -axis. Since we are given y in terms of x , we choose shells. The radius of each shell is x and the height is $x - x^2$, so the volume is

$$V = 2\pi \int_0^1 x (x - x^2) dx = 2\pi \int_0^1 (x^2 - x^3) dx = 2\pi \left[\frac{1}{3}x^3 - \frac{1}{4}x^4 \right]_0^1 = \boxed{\frac{\pi}{6}}.$$

36. The region is shown below:

If we use washers along the y -axis, we will have to solve this equation for x in terms of y , and also split it into two integrals. So using shells along the x -axis is much easier. The radius of each shell is x , and the height is $x^{2/3} + x^{1/3}$, so the volume is

$$V = 2\pi \int_1^8 x \left(x^{2/3} + x^{1/3} \right) dx = 2\pi \int_1^8 \left(x^{5/3} + x^{4/3} \right) dx = 2\pi \left[\frac{3}{8}x^{8/3} + \frac{3}{7}x^{7/3} \right]_1^8 = \boxed{\frac{8403}{28}\pi}.$$

37. The region is shown below:

Revolving about the y -axis, if we use washers along the y -axis we will require two separate integrals. So use shells along the x -axis. The radius of each shell is x , and the height is $18 - x^2 - \sqrt{x}$, so the volume is

$$V = 2\pi \int_1^4 x(18 - x^2 - \sqrt{x}) dx = 2\pi \int_1^4 \left(18x - x^3 - x^{3/2} \right) dx = 2\pi \left[9x^2 - \frac{1}{4}x^4 - \frac{2}{5}x^{5/2} \right]_1^4 = \boxed{\frac{1177}{10}\pi}.$$

38. This is the same region as in Problem 37, but revolved about the x -axis. A similar argument applies: if we use shells along the y -axis, we will need two separate integrals, since the radius changes equations at $y = 2$. So use washers along the x -axis. The outer radius is $18 - x^2$, and the inner radius is $\sqrt{x}$. Therefore the volume is

$$\begin{aligned} V &= \pi \int_1^4 \left((18 - x^2)^2 - (\sqrt{x})^2 \right) dx \\ &= \pi \int_1^4 \left(x^4 - 36x^2 - x + 324 \right) dx \\ &= \pi \left[\frac{1}{5}x^5 - 12x^3 - \frac{1}{2}x^2 + 324x \right]_1^4 \\ &= \boxed{\frac{4131}{10}\pi}. \end{aligned}$$

Applications and Extensions

39. Use the shell method along the x -axis. The radius of each shell is x and the height is $\frac{1}{(x^2+1)^2}$, so the volume is

$$V = 2\pi \int_0^1 \frac{x}{(x^2+1)^2} dx.$$

Now use the substitution $u = x^2 + 1$, so that $du = 2x dx$. Then $x = 0$ corresponds to $u = 1$, and $x = 1$ to $u = 2$, so that we get

$$V = 2\pi \cdot \frac{1}{2} \int_1^2 \frac{1}{u^2} du = \pi \left[-\frac{1}{u} \right]_1^2 = \boxed{\frac{\pi}{2}}.$$

40. The region is shown below:

The disk/washer method along the y -axis requires solving the equation for x , which looks difficult. So we use the shell method along the x -axis. The radius of each shell is x , and the height is $\sqrt{x+1} + x$, so the volume is

$$V = 2\pi \int_0^3 x (\sqrt{x+1} + x) dx = 2\pi \left(\int_0^3 x\sqrt{x+1} dx + \int_0^3 x^2 dx \right).$$

For the first integral, use the substitution $u = x + 1$, so that $x = u - 1$ and $du = dx$. Then $x = 0$ corresponds to $u = 1$ while $x = 3$ corresponds to $u = 4$. So we get

$$\begin{aligned} V &= 2\pi \left(\int_1^4 (u-1)\sqrt{u} du + \int_0^3 x^2 dx \right) \\ &= 2\pi \left(\int_1^4 (u^{3/2} - u^{1/2}) du + \int_0^3 x^2 dx \right) \\ &= 2\pi \left(\left[\frac{2}{5} u^{5/2} - \frac{2}{3} u^{3/2} \right]_1^4 + \left[\frac{1}{3} x^3 \right]_0^3 \right) \\ &= \boxed{\frac{502}{15} \pi}. \end{aligned}$$

41. The region is shown below:

- (a) To revolve about the x -axis, use the disk method. The radius of each disk is $2x - x^2$, so the volume is

$$V = \pi \int_0^2 (2x - x^2)^2 dx = \pi \int_0^2 (4x^2 - 4x^3 + x^4) dx = \pi \left[\frac{4}{3}x^3 - x^4 + \frac{1}{5}x^5 \right]_0^2 = \boxed{\frac{16}{15}\pi}.$$

- (b) To revolve about the y -axis, use the shell method along the x -axis. The radius of each shell is x and its height is $2x - x^2$, so the volume is

$$V = 2\pi \int_0^2 x(2x - x^2) dx = 2\pi \int_0^2 (2x^2 - x^3) dx = 2\pi \left[\frac{2}{3}x^3 - \frac{1}{4}x^4 \right]_0^2 = \boxed{\frac{8}{3}\pi}.$$

- (c) To revolve about the line $x = 3$, use the shell method along the x -axis. The radius of each shell is $3 - x$ (the distance from x to 3), and the height is $2x - x^2$, so the volume is

$$V = 2\pi \int_0^2 (3 - x)(2x - x^2) dx = 2\pi \int_0^2 (x^3 - 5x^2 + 6x) dx = 2\pi \left[\frac{1}{4}x^4 - \frac{5}{3}x^3 + 3x^2 \right]_0^2 = \boxed{\frac{16}{3}\pi}.$$

- (d) To revolve about the line $y = 1$, use the washer method along the x -axis. The outer radius of each shell is $1 - 0 = 1$, and the inner radius is $1 - (2x - x^2) = x^2 - 2x + 1 = (x - 1)^2$. Therefore the volume is

$$V = \pi \int_0^2 \left(1^2 - ((x - 1)^2)^2 \right) dx = \pi \int_0^2 (1 - (x - 1)^4) dx = \pi \left[x - \frac{1}{5}(x - 1)^5 \right]_0^2 = \boxed{\frac{8}{5}\pi}.$$

42. The region is shown below:

- (a) To revolve about the x -axis, use the disk method. The radius of each disk is $x\sqrt{9-x}$, so the volume is

$$V = \pi \int_0^9 (x\sqrt{9-x})^2 dx = \pi \int_0^9 (9x^2 - x^3) dx = \pi \left[3x^3 - \frac{1}{4}x^4 \right]_0^9 = \boxed{\frac{2187}{4}\pi}.$$

- (b) To revolve about the y -axis, use the shell method along the x -axis. The radius of each shell is x and its height is $x\sqrt{9-x}$, so the volume is

$$V = 2\pi \int_0^9 x (x\sqrt{9-x}) dx = 2\pi \int_0^9 x^2 \sqrt{9-x} dx.$$

Now use the substitution $u = 9 - x$, so that $x = 9 - u$ and $du = -dx$. Then $x = 0$ corresponds to $u = 9$ and $x = 9$ corresponds to $u = 0$, so that we get

$$\begin{aligned} V &= -2\pi \int_9^0 (9-u)^2 \sqrt{u} du \\ &= 2\pi \int_0^9 (u^{5/2} - 18u^{3/2} + 81u^{1/2}) du \\ &= 2\pi \left[\frac{2}{7}u^{7/2} - \frac{36}{5}u^{5/2} + 54u^{3/2} \right]_0^9 \\ &= \boxed{\frac{23328}{35}\pi}. \end{aligned}$$

- (c) To revolve about the line $y = -3$, use the washer method along the x -axis. The outer radius of each shell is $x\sqrt{9-x} - (-3) = x\sqrt{9-x} + 3$, and the inner radius is $0 - (-3) = 3$. Therefore the volume is

$$\begin{aligned} V &= \pi \int_0^9 ((x\sqrt{9-x} + 3)^2 - 3^2) dx \\ &= \pi \int_0^9 (x^2(9-x) + 6x\sqrt{9-x}) dx \\ &= \pi \left(\int_0^9 (9x^2 - x^3) dx + 6 \int_0^9 x\sqrt{9-x} dx \right). \end{aligned}$$

For the second integral, use the substitution $u = 9 - x$, so that $x = 9 - u$ and $du = -dx$. Then $x = 0$ corresponds to $u = 9$ and $x = 9$ corresponds to $u = 0$, so that we get

$$\begin{aligned} V &= \pi \left(\int_0^9 (9x^2 - x^3) dx - 6 \int_9^0 (9-u)\sqrt{u} du \right) \\ &= \pi \left(\int_0^9 (9x^2 - x^3) dx + 6 \int_0^9 (9u^{1/2} - u^{3/2}) du \right) \\ &= \pi \left(\left[3x^3 - \frac{1}{4}x^4 \right]_0^9 + 6 \left[6u^{3/2} - \frac{2}{5}u^{5/2} \right]_0^9 \right) \\ &= \boxed{\frac{18711}{20}\pi}. \end{aligned}$$

- (d) To revolve about the line $x = -2$, use the shell method along the x -axis. The radius of each shell is $x - (-2) = x + 2$ (the distance from x to -2), and the height is $x\sqrt{9-x}$, so the volume is

$$V = 2\pi \int_0^9 (x+2)x\sqrt{9-x} dx = 2\pi \int_0^9 (x^2 + 2x)\sqrt{9-x} dx.$$

Again we use the substitution $u = 9 - x$, so that $x = 9 - u$, $x^2 + 2x = u^2 - 20u + 99$, and $du = -dx$. Then $x = 0$ corresponds to $u = 9$ and $x = 9$ corresponds to $u = 0$, so that we get

$$\begin{aligned} V &= -2\pi \int_9^0 (u^2 - 20u + 99) \sqrt{u} \, du \\ &= 2\pi \int_0^9 (u^{5/2} - 20u^{3/2} + 99u^{1/2}) \, du \\ &= 2\pi \left[\frac{2}{7} u^{7/2} - 8u^{5/2} + 66u^{3/2} \right]_0^9 \\ &= \boxed{\frac{6480}{7}\pi}. \end{aligned}$$

43. Using the disk method to compute the volume gives

$$\pi \int_0^k f(x)^2 \, dx = \frac{1}{5}k^5 + k^4 + \frac{4}{3}k^3.$$

Assuming that the antiderivative of $f(x)^2$, evaluated at 0 is zero, we see that $\frac{1}{5}k^5 + k^4 + \frac{4}{3}k^3$ is π times the antiderivative of $f(x)^2$ evaluated at $x = k$. Therefore $f(x)^2$ has as an antiderivative $\frac{1}{\pi} (\frac{1}{5}x^5 + x^4 + \frac{4}{3}x^3)$, so that $f(x)^2 = \frac{1}{\pi} (x^4 + 4x^3 + 4x^2) = \frac{1}{\pi} x^2 (x^2 + 4x + 4) = \frac{1}{\pi} (x(x+2))^2$. Since

we are given that $f(x) \geq 0$, taking square roots gives $f(x) = \frac{1}{\sqrt{\pi}} x(x+2) = \boxed{\frac{1}{\sqrt{\pi}} (x^2 + 2x)}$.

44. We first determine the inflection point. With $f(x) = e^{-x^2}$, we have $f'(x) = -2xe^{-x^2}$, so that

$$f''(x) = -2x(-2xe^{-x^2}) - 2e^{-x^2} = (4x^2 - 2)e^{-x^2}.$$

Then $f''(x) = 0$ when $x = \pm \frac{1}{\sqrt{2}}$; since we want the positive value, we get $x = \frac{1}{\sqrt{2}}$. Therefore the region in question is the following:

To revolve this about the y -axis, it appears easiest to use the shell method along the x -axis. The radius of each shell is x and its height is e^{-x^2} , so we get for the volume

$$V = 2\pi \int_0^{1/\sqrt{2}} x e^{-x^2} \, dx.$$

Use the substitution $u = -x^2$, so that $du = -2x \, dx$. Then $x = 0$ corresponds to $u = 0$ while $x = \frac{1}{\sqrt{2}}$ corresponds to $u = -\frac{1}{2}$. So we get for the integral

$$V = 2\pi \cdot \left(-\frac{1}{2}\right) \int_0^{-1/2} e^u \, du = -\pi [e^u]_0^{-1/2} = \boxed{\left(1 - \frac{1}{e^{1/2}}\right)\pi}.$$

45. The region is shown below:

We should use the shell method, as the washer method will involve solving $y = \sin^3 x$ for x and then integrating. With the shell method, the radius of each shell is $x - (-\pi) = x + \pi$, and the height is $\sin^3 x$. Therefore the volume is (using a CAS)

$$V = 2\pi \int_0^\pi (x + \pi) \sin^3 x \, dx \approx 12.566\pi \approx 39.478 \approx 4\pi^2.$$

Challenge Problems

46. (a) From the diagram, $f(x)$ is constant and equal to $f(a)$ for $0 \leq x \leq a$, and also $g(x)$ is constant and equal to $g(a)$ for $0 \leq x \leq a$. So using the shell method, we get two separate integrals, one on $[0, a]$ and one on $[a, b]$. For the first, the radius of each shell is x and the height is $f(x) - g(x) = f(a) - g(a)$, while for the second, the radius is x and the height is $f(x) - g(x)$. Therefore the volume of the solid is

$$\begin{aligned} V &= 2\pi \left(\int_0^a x[f(a) - g(a)] \, dx + \int_a^b x[f(x) - g(x)] \, dx \right) \\ &= 2\pi \left(\left[\frac{1}{2}x^2[f(a) - g(a)] \right]_0^a + \int_a^b x[f(x) - g(x)] \, dx \right) \\ &= \pi a^2[f(a) - g(a)] + 2\pi \int_a^b x[f(x) - g(x)] \, dx. \end{aligned}$$

- (b) Using the disk method, we also get two separate integrals, one from $y = g(a)$ to $y = g(b) = f(b)$ and one from $y = f(b)$ to $y = f(a)$. For the first integral, the radius of the disk is $g^{-1}(y)$ and for the second it is $f^{-1}(y)$. Therefore the volume is the sum of these integrals, or

$$V = \pi \int_{g(a)}^{g(b)} [g^{-1}(y)]^2 \, dy + \pi \int_{f(b)}^{f(a)} [f^{-1}(y)]^2 \, dy.$$

47. Consider the region A . Suppose that it is wholly contained between the vertical lines $x = a > 0$ and $x = b > a$. Integrate it using the shell method. At any $x \geq 0$, A consists of one or more line segments. Define $g(x)$ to be the total length of all of those segments at x . Then using the shell method, the volume of the solid of revolution about the y -axis is

$$V = 2\pi \int_a^b xg(x) \, dx.$$

When revolving A about the line $x = -k$, the heights at x are the same, $g(x)$, but the radius in each case is now $x + k$. So using the shell method in this case gives

$$V_{x=-k} = 2\pi \int_a^b (x + k)g(x) \, dx = 2\pi \int_a^b xg(x) \, dx + 2\pi \int_a^b kg(x) \, dx = V + 2\pi k \int_a^b g(x) \, dx = V + 2\pi kA,$$

as desired.

48. For this parabola, the latus rectum is the line $x = 2$; we wish to revolve the area to the left of this line about that line.

- (a) Using the disk method, we must solve the equation for x in terms of y , giving $x = \frac{y^2}{8}$. Then the radius of each disk is $2 - \frac{y^2}{8}$, so that the volume of the solid is

$$V = \pi \int_{-4}^4 \left(2 - \frac{y^2}{8}\right)^2 dy = \pi \int_{-4}^4 \left(4 - \frac{y^2}{2} + \frac{y^4}{64}\right) dy = \pi \left[4y - \frac{y^3}{6} + \frac{y^5}{320}\right]_{-4}^4 = \boxed{\frac{256}{15}\pi}.$$

- (b) Using the shell method, the radius of each shell is $2 - x$, and the height of each shell is then $\sqrt{8x} - (-\sqrt{8x}) = 2\sqrt{8x} = 4x^{1/2}\sqrt{2}$, so that the volume is

$$\begin{aligned} V &= 2\pi \int_0^2 (2 - x) (4x^{1/2}\sqrt{2}) dx \\ &= 8\sqrt{2}\pi \int_0^2 (2x^{1/2} - x^{3/2}) dx \\ &= 8\sqrt{2}\pi \left[\frac{4}{3}x^{3/2} - \frac{2}{5}x^{5/2}\right]_0^2 \\ &= \boxed{\frac{256}{15}\pi}. \end{aligned}$$

6.4: Volume of a Solid: Slicing Method

Concepts and Vocabulary

- Answers vary. When computing the volume of a solid whose cross sections have a regular geometric shape whose area we can compute, we can integrate over the area of each slice of the solid along one of its axes.
- False. For instance, Example 3 uses the method of slicing to compute the volume of a square pyramid, which is not a solid of revolution. The slicing method can be used effectively whenever the cross sections have a regular geometric shape whose area we can compute.

Skill Building

- The equation of the circle is $x^2 + y^2 = 4$, so that for a given value of x , y can range from $-\sqrt{4 - x^2}$ to $\sqrt{4 - x^2}$. Therefore, for each value of x from -2 to 2 , the cross section is a square of side $2\sqrt{4 - x^2}$, so that its area is $4(4 - x^2)$. Therefore the volume of the solid is

$$V = \int_{-2}^2 4(4 - x^2) dx = 4 \int_{-2}^2 (4 - x^2) dx = 4 \left[4x - \frac{1}{3}x^3\right]_{-2}^2 = \boxed{\frac{128}{3}}.$$

- The equation of the circle is $x^2 + y^2 = 4$, so that for a given value of x , y can range from $-\sqrt{4 - x^2}$ to $\sqrt{4 - x^2}$. Therefore, for each value of x from -2 to 2 , the cross section is an isosceles right triangle one of whose legs is $2\sqrt{4 - x^2}$, so that its area is $\frac{1}{2}(2\sqrt{4 - x^2})^2 = 2(4 - x^2)$. Therefore the volume of the solid is

$$V = \int_{-2}^2 2(4 - x^2) dx = 2 \int_{-2}^2 (4 - x^2) dx = 2 \left[4x - \frac{1}{3}x^3\right]_{-2}^2 = \boxed{\frac{64}{3}}.$$

5. Place the origin at the tip of the pyramid, with the x -axis along the axis of the pyramid. Then at x , the cross section is a square with side length $2x$ meters, so that its area is $4x^2$ square meters. Therefore the volume of the pyramid is

$$V = \int_0^{40} 4x^2 dx = \left[\frac{4}{3}x^3 \right]_0^{40} = \boxed{\frac{256000}{3} \text{ meters}^3}.$$

6. Place the origin at the tip of the pyramid, with the x -axis along the axis of the pyramid. Then at x , the cross section is a rectangle with sides x and $2x$ meters, so that its area is $2x^2$ square meters. Therefore the volume of the pyramid is

$$V = \int_0^{20} 2x^2 dx = \left[\frac{2}{3}x^3 \right]_0^{20} = \boxed{\frac{16000}{3} \text{ meters}^3}.$$

7. From the figure, these two curves intersect at $(0,0)$ and at $(4,2)$, so that we will integrate from 0 to 4. For each value of x , the cross section is a semicircle of diameter $\sqrt{x} - \frac{1}{8}x^2$, so that its area is

$$A = \frac{1}{2}\pi r^2 = \frac{1}{2}\pi \left(\frac{\sqrt{x} - \frac{1}{8}x^2}{2} \right)^2 = \frac{\pi}{512} (8\sqrt{x} - x^2)^2 = \frac{\pi}{512} (64x - 16x^{5/2} + x^4).$$

Therefore the volume is

$$V = \int_0^4 \frac{\pi}{512} (64x - 16x^{5/2} + x^4) dx = \frac{\pi}{512} \left[32x^2 - \frac{32}{7}x^{7/2} + \frac{1}{5}x^5 \right]_0^4 = \boxed{\frac{9}{35}\pi}.$$

8. From the figure for Problem 7, these two curves intersect at $(0,0)$ and at $(4,2)$, so that we will integrate from 0 to 4. For each value of x , the cross section is a triangle whose base is $\sqrt{x} - \frac{1}{8}x^2$ and whose height is $3(\sqrt{x} - \frac{1}{8}x^2)$. Therefore its area is

$$A = \frac{1}{2}bh = \frac{3}{2} \left(\sqrt{x} - \frac{1}{8}x^2 \right)^2 = \frac{3}{2} \left(x - \frac{1}{4}x^{5/2} + \frac{1}{64}x^4 \right) = \frac{3}{2}x - \frac{3}{8}x^{5/2} + \frac{3}{128}x^4.$$

Therefore the volume is

$$V = \int_0^4 \left(\frac{3}{2}x - \frac{3}{8}x^{5/2} + \frac{3}{128}x^4 \right) dx = \left[\frac{3}{4}x^2 - \frac{3}{28}x^{7/2} + \frac{3}{640}x^5 \right]_0^4 = \boxed{\frac{108}{35}}.$$

9. The region is shown below:

For each x , the cross section is a circle whose diameter is $\frac{4}{3}x^{1/3} - x^{1/2}$, so the area of that circle is

$$A = \pi r^2 = \pi \left(\frac{\frac{4}{3}x^{1/3} - x^{1/2}}{2} \right)^2 = \pi \left(\frac{4}{9}x^{2/3} - \frac{2}{3}x^{5/6} + \frac{1}{4}x \right).$$

Therefore the volume is

$$V = \int_0^1 \pi \left(\frac{4}{9}x^{2/3} - \frac{2}{3}x^{5/6} + \frac{1}{4}x \right) dx = \pi \left[\frac{12}{45}x^{5/3} - \frac{12}{33}x^{11/6} + \frac{1}{8}x^2 \right]_0^1 = \boxed{\frac{37}{1320}\pi}.$$

10. The region is shown below:

For each x , the cross section is a circle whose diameter is $\frac{3}{2}x^{1/3} - x^{1/3} = \frac{1}{2}x^{1/3}$, so the area of that circle is

$$A = \pi r^2 = \pi \left(\frac{\frac{1}{2}x^{1/3}}{2} \right)^2 = \frac{1}{16}\pi x^{2/3}.$$

Therefore the volume is

$$V = \int_0^1 \left(\frac{1}{16}\pi x^{2/3} \right) dx = \frac{1}{16}\pi \left[\frac{3}{5}x^{5/3} \right]_0^1 = \boxed{\frac{3}{80}\pi}.$$

11. The region is shown below:

For each x , the cross section is a semicircle whose diameter is $x^2 - 0 = x^2$, so the area of that semicircle is $\frac{1}{2}\pi \left(\frac{x}{2} \right)^2 = \frac{1}{8}\pi x^2$. Therefore the volume of the solid is

$$V = \int_0^1 \frac{1}{8}\pi x^2 dx = \left[\frac{1}{24}\pi x^3 \right]_0^1 = \boxed{\frac{1}{24}\pi}.$$

12. The region is shown below:

For each x , the cross section is a semicircle whose diameter is $3\sqrt{3x} - x^2$, so the area of that semicircle is

$$A = \frac{1}{2}\pi r^2 = \frac{1}{2}\pi \left(\frac{3\sqrt{3x} - x^2}{2} \right)^2 = \frac{1}{8}\pi (3\sqrt{3x} - x^2)^2 = \frac{1}{8}\pi (27x - 6\sqrt{3}x^{5/2} + x^4).$$

Therefore the volume of the solid is

$$V = \int_0^3 \frac{1}{8}\pi (27x - 6\sqrt{3}x^{5/2} + x^4) dx = \frac{1}{8}\pi \left[\frac{27}{2}x^2 - \frac{12\sqrt{3}}{7}x^{7/2} + \frac{1}{5}x^5 \right]_0^3 = \boxed{\frac{2187}{560}\pi}.$$

Applications and Extensions

13. Place the center of the sphere at the origin. Then x ranges from $-R$ to R , so that for each x , the possible values of y are from $-\sqrt{R^2 - x^2}$ to $\sqrt{R^2 - x^2}$. Therefore the cross section at x is a circle with radius $\sqrt{R^2 - x^2}$, so its area is $\pi(\sqrt{R^2 - x^2})^2 = \pi(R^2 - x^2)$. So the total volume of the sphere is

$$V = \int_{-R}^R \pi(R^2 - x^2) dx = \pi \left[R^2x - \frac{1}{3}x^3 \right]_{-R}^R = \pi \cdot \frac{4}{3}R^3 = \boxed{\frac{4}{3}\pi R^3}.$$

14. Place the center of the top of the hemispherical bowl at the origin, with the x -axis pointing down (so the bottom of the bowl is at $(R, 0)$). Then x ranges from $R - h$ to R , and for each x , the possible values of y are from $-\sqrt{R^2 - x^2}$ to $\sqrt{R^2 - x^2}$. Therefore the cross section at x is a circle with radius $\sqrt{R^2 - x^2}$, so its area is $\pi(\sqrt{R^2 - x^2})^2 = \pi(R^2 - x^2)$. So the total volume of the contents is

$$\begin{aligned} V &= \int_{R-h}^R \pi(R^2 - x^2) dx \\ &= \pi \left[R^2x - \frac{1}{3}x^3 \right]_{R-h}^R \\ &= \pi \left(R^3 - \frac{1}{3}R^3 - R^2(R-h) + \frac{1}{3}(R-h)^3 \right) \\ &= \pi \left(R^2h - R^2h + Rh^2 - \frac{1}{3}h^3 \right) \\ &= \boxed{\pi h^2 \left(R - \frac{h}{3} \right)}. \end{aligned}$$

Note that if $h = 0$ (the bowl is empty), this gives 0, while if $h = R$ (the bowl is completely full), it gives $\frac{2}{3}\pi R^3$, which is indeed half the volume of a sphere of radius R .

15. A diagram of the water in the glass, in a three-dimensional view on the left and a two-dimensional projection on the right, is shown below:

For a given value of x , the length of the water line along the base is $2\sqrt{r^2 - x^2}$, since the base is a circle of radius r . To determine its height, use similar triangles (look at the two-dimensional picture): if H is the height, then $\frac{H}{x} = \frac{h}{r}$, so that $H = \frac{h}{r}x$. So the cross section at x is a rectangle with dimensions $2\sqrt{r^2 - x^2} \times \frac{h}{r}x$. Therefore the volume of this amount of water is

$$V = \int_0^r \frac{h}{r}x \cdot 2\sqrt{r^2 - x^2} dx.$$

16. Place the origin at the point where the dotted line in the diagram meets the sharp edge of the solid, with the x -axis along that sharp edge. Note that since the cylinder has diameter 10, the wedge penetrates halfway through the cylinder, so that the x -axis coordinates of the wedge range from -5 to 5 . Now, for each value of x , the distance from the x -axis to the outer edge of the wedge is $\sqrt{25 - x^2}$, and the height of the wedge at that point is $\sqrt{25 - x^2} \cdot \tan 30^\circ = \frac{\sqrt{3}}{3}\sqrt{25 - x^2}$. The cross section is therefore a right triangle whose area is

$$A = \frac{1}{2}bh = \frac{1}{2}\sqrt{25 - x^2} \cdot \frac{\sqrt{3}}{3}\sqrt{25 - x^2} = \frac{\sqrt{3}}{6}(25 - x^2).$$

So the volume of the wedge is

$$V = \int_{-5}^5 \frac{\sqrt{3}}{6}(25 - x^2) dx = \frac{\sqrt{3}}{6} \left[25x - \frac{1}{3}x^3 \right]_{-5}^5 = \frac{250\sqrt{3}}{9} \text{ m}^3.$$

17. The region is shown below:

The diameter of each slice is $e^{-x^2} - (-e^{-x^2}) = 2e^{-x^2}$, so the area of each slice is

$$A = \pi r^2 = \pi \left(\frac{1}{2} \cdot 2e^{-x^2} \right)^2 = \pi e^{-2x^2}.$$

Therefore the volume is (using a CAS)

$$V = \pi \int_{-1}^1 e^{-2x^2} dx \approx 3.758.$$

18. Answers may vary. The slicing method uses the area of a slice as the integrand, where that area is described by some “nice” rule. In the case of the slice method applied to a solid of revolution of $f(x)$, each slice is a circle whose radius is $f(x)$, so its area is $\pi f(x)^2$, so that the total volume is $\int_a^b \pi f(x)^2 dx = \pi \int_a^b f(x)^2 dx$, which is exactly the formula for applying the disk method to this solid of revolution.

Challenge Problems

19. The volume removed is almost a cylinder with radius 2, except for the ends, which are spherical caps. Let's first determine the x -coordinate of the point where the bore reaches the edge of the sphere (which is the “edge” in the front of the diagram). We have $x^2 + y^2 = 25$, since the sphere has radius 5. But at this point, $y = 2$, so that $x^2 = 21$ and $x = \sqrt{21}$. Then the volume of metal removed consists of three pieces: a cylinder of height $2\sqrt{21}$ and radius 2, and two spherical “caps” of height $5 - \sqrt{21}$ taken from a sphere of radius 5. We can compute the volume of those spherical caps using Problem 14 with $R = 5$ and $h = 5 - \sqrt{21}$, giving a volume of

$$\pi h^2 \left(R - \frac{h}{3} \right) = \pi (5 - \sqrt{21})^2 \left(5 - \frac{5 - \sqrt{21}}{3} \right) = \pi \left(\frac{250}{3} - 18\sqrt{21} \right).$$

Then the total volume of the bore is

$$\begin{aligned} V &= \text{volume of cylinder} + 2 \text{ volume of cap} \\ &= \pi \cdot 2^2 \cdot 2\sqrt{21} + 2\pi \left(\frac{250}{3} - 18\sqrt{21} \right) = \pi \left(\frac{500}{3} - 28\sqrt{21} \right). \end{aligned}$$

20. Place the pipes so that their axes lie along the x and y -axes. Two plots of the pipes are below; the one on the right is the view from above.

Consider a horizontal slice through the pipes at a distance R from the xy -plane. The cross section of one pipe is the lines $x = \pm\sqrt{r^2 - R^2}$ and the cross section of the other is the lines $y = \pm\sqrt{r^2 - R^2}$. Therefore the slice representing the cross sectional area contained in both pipes at this level is a square of side $2\sqrt{r^2 - R^2}$ (see the right-hand diagram). The possible distance R range from $-r$ to r , so the volume of the solid bounded by both pipes is

$$V = \int_{-r}^r \left(2\sqrt{r^2 - R^2}\right)^2 dR = 4 \int_{-r}^r (r^2 - R^2) dR = 4 \left[r^2 R - \frac{1}{3} R^3 \right]_{-r}^r = \boxed{\frac{16}{3} r^3}.$$

21. Place the origin at the tip of the cone, with the positive x -axis pointing in the direction of the base, so that the base of the cone is an ellipse at $x = h$:

Then for a given value of x , similar triangles tell us that the cross section at x is an ellipse with major axis $2a\frac{x}{h}$ and minor axis $2b\frac{x}{h}$. We must integrate over the area of these ellipses. Now by the hint, the area of each ellipse is

$$\pi \cdot \left(a\frac{x}{h}\right) \cdot \left(b\frac{x}{h}\right) = \pi \frac{ab}{h^2} x^2,$$

so the volume is

$$V = \int_0^h \left(\pi \frac{ab}{h^2} x^2\right) dx = \pi \frac{ab}{h^2} \left[\frac{1}{3} x^3\right]_0^h = \boxed{\frac{1}{3} \pi abh}.$$

22. The parallelepiped is made up of a number of slices, each of which is a parallelogram with sides a and b where the angle between a and b is θ . The area of such a parallelogram is $ab \sin \theta$. The height of the parallelepiped is $c \sin \phi$, so the volume is

$$V = \int_0^{c \sin \phi} ab \sin \theta dx = \boxed{abc \sin \phi \sin \theta}.$$

6.5: Arc Length

Concepts and Vocabulary

- False. The integrand should be $\sqrt{1 + [f'(x)]^2}$, not $\sqrt{1 + [f(x)]^2}$: $s = \int_a^b \sqrt{1 + [f'(x)]^2} dx$.
- True. By regarding f as a piecewise continuous function, we may be able to find the arc length of each continuous piece and add up all the pieces.

Skill Building

- With $f(x) = 3x - 1$, we have $f'(x) = 3$. Since $f'(x)$ is continuous everywhere, the Arc Length Formula applies, so that the arc length is

$$s = \int_1^3 \sqrt{1^2 + 3^2} dx = \int_1^3 \sqrt{10} dx = \boxed{2\sqrt{10}}.$$

Using the Distance Formula, we get $s = \sqrt{(3-1)^2 + (8-2)^2} = \sqrt{4+36} = \sqrt{40} = 2\sqrt{10}$, and the answers are the same.

- With $f(x) = -4x + 1$, we have $f'(x) = -4$. Since $f'(x)$ is continuous everywhere, the Arc Length Formula applies, so that the arc length is

$$s = \int_{-1}^1 \sqrt{1^2 + (-4)^2} dx = \int_{-1}^1 \sqrt{17} dx = \boxed{2\sqrt{17}}.$$

Using the Distance Formula, we get $s = \sqrt{(1 - (-1))^2 + (-3 - 5)^2} = \sqrt{2^2 + 8^2} = \sqrt{68} = 2\sqrt{17}$, and the answers are the same.

- First solve for y , giving $y = \frac{2}{3}x + \frac{4}{3}$ and $y' = \frac{2}{3}$. Since $f'(x)$ is continuous everywhere, the Arc Length Formula applies, so that the arc length is

$$s = \int_1^4 \sqrt{1^2 + \left(\frac{2}{3}\right)^2} dx = \int_1^4 \frac{\sqrt{13}}{3} dx = \boxed{\sqrt{13}}.$$

Using the Distance Formula, we get $s = \sqrt{(4-1)^2 + (4-2)^2} = \sqrt{9+4} = \sqrt{13}$, and the answers are the same.

- First solve for y , giving $y = -\frac{3}{4}x + 3$ and $y' = -\frac{3}{4}$. Since $f'(x)$ is continuous everywhere, the Arc Length Formula applies, so that the arc length is

$$s = \int_0^4 \sqrt{1^2 + \left(-\frac{3}{4}\right)^2} dx = \int_0^4 \frac{5}{4} dx = \boxed{5}.$$

Using the Distance Formula, we get $s = \sqrt{(4-0)^2 + (0-3)^2} = \sqrt{16+9} = 5$, and the answers are the same.

- The derivative of $y = x^{2/3} + 1$ is $y = \frac{2}{3}x^{-1/3}$, so that y has a continuous derivative on an interval containing 1 and 8. Therefore the Arc Length Formula applies, and the arc length is

$$s = \int_1^8 \sqrt{1^2 + \left(\frac{2}{3}x^{-1/3}\right)^2} dx = \frac{1}{3} \int_1^8 \sqrt{9 + 4x^{-2/3}} dx = \frac{1}{3} \int_1^8 x^{-1/3} \sqrt{9x^{2/3} + 4} dx.$$

Now use the substitution $u = 9x^{2/3} + 4$, so that $du = 6x^{-1/3} dx$. Then $x = 1$ corresponds to $u = 13$ while $x = 8$ corresponds to $u = 40$, and we get

$$s = \frac{1}{3} \cdot \frac{1}{6} \int_{13}^{40} \sqrt{u} du = \frac{1}{18} \left[\frac{2}{3} u^{3/2} \right]_{13}^{40} = \frac{1}{27} (40^{3/2} - 13^{3/2}) = \boxed{\frac{1}{27} (80\sqrt{10} - 13\sqrt{13})}.$$

8. The derivative of $y = x^{2/3} + 6$ is $y' = \frac{2}{3}x^{-1/3}$, so that y has a continuous derivative on an interval containing 1 and 8. Therefore the Arc Length Formula applies, and the arc length is

$$s = \int_1^8 \sqrt{1^2 + \left(\frac{2}{3}x^{-1/3}\right)^2} dx = \frac{1}{3} \int_1^8 \sqrt{9 + 4x^{-2/3}} dx = \frac{1}{3} \int_1^8 x^{-1/3} \sqrt{9x^{2/3} + 4} dx.$$

Now use the substitution $u = 9x^{2/3} + 4$, so that $du = 6x^{-1/3} dx$. Then $x = 1$ corresponds to $u = 13$ while $x = 8$ corresponds to $u = 40$, and we get

$$s = \frac{1}{3} \cdot \frac{1}{6} \int_{13}^{40} \sqrt{u} du = \frac{1}{18} \left[\frac{2}{3} u^{3/2} \right]_{13}^{40} = \frac{1}{27} (40^{3/2} - 13^{3/2}) = \boxed{\frac{1}{27} (80\sqrt{10} - 13\sqrt{13})}.$$

9. The derivative of $y = x^{3/2}$ is $y' = \frac{3}{2}x^{1/2}$, so that y has a continuous derivative on an interval containing 0 and 4. Therefore the Arc Length Formula applies, and the arc length is

$$s = \int_0^4 \sqrt{1^2 + \left(\frac{3}{2}x^{1/2}\right)^2} dx = \frac{1}{2} \int_0^4 \sqrt{4 + 9x} dx.$$

Now substitute $u = 4 + 9x$; then $du = 9 dx$. Further, $x = 0$ corresponds to $u = 4$ while $x = 4$ corresponds to $u = 40$, so we get

$$\frac{1}{2} \int_0^4 \sqrt{4 + 9x} dx = \frac{1}{2} \cdot \frac{1}{9} \int_4^{40} u^{1/2} du = \frac{1}{18} \left[\frac{2}{3} u^{3/2} \right]_4^{40} = \frac{1}{27} (40\sqrt{40} - 8) = \boxed{\frac{1}{27} (80\sqrt{10} - 8)}.$$

10. The derivative of $y = x^{3/2} + 4$ is $y' = \frac{3}{2}x^{1/2}$, so that y has a continuous derivative on an interval containing 1 and 4. Therefore the Arc Length Formula applies, and the arc length is

$$s = \int_1^4 \sqrt{1^2 + \left(\frac{3}{2}x^{1/2}\right)^2} dx = \frac{1}{2} \int_1^4 \sqrt{4 + 9x} dx.$$

Now substitute $u = 4 + 9x$; then $du = 9 dx$. Further, $x = 1$ corresponds to $u = 13$ while $x = 4$ corresponds to $u = 40$, so we get

$$\begin{aligned} \frac{1}{2} \int_1^4 \sqrt{4 + 9x} dx &= \frac{1}{2} \cdot \frac{1}{9} \int_{13}^{40} u^{1/2} du = \frac{1}{18} \left[\frac{2}{3} u^{3/2} \right]_{13}^{40} \\ &= \frac{1}{27} (40\sqrt{40} - 13\sqrt{13}) = \boxed{\frac{1}{27} (80\sqrt{10} - 13\sqrt{13})}. \end{aligned}$$

11. First solve for y , giving (since we are given $y \geq 0$) $y = \frac{2}{3}x^{3/2}$. Then $y' = x^{1/2}$ has a continuous derivative on an interval containing 0 and 1, so that the Arc Length Formula applies, and the arc length is

$$s = \int_0^1 \sqrt{1^2 + (x^{1/2})^2} dx = \int_0^1 \sqrt{1 + x} dx = \left[\frac{2}{3} (1 + x)^{3/2} \right]_0^1 = \boxed{\frac{2}{3} (2\sqrt{2} - 1)}.$$

12. We have $y' = \frac{x^2}{2} - \frac{1}{2x^2}$, which is continuous on an interval containing 1 and 3. Therefore the Arc Length Formula applies, and the arc length is

$$\begin{aligned}
 s &= \int_1^3 \sqrt{1^2 + \left(\frac{x^2}{2} - \frac{1}{2x^2}\right)^2} dx \\
 &= \int_1^3 \sqrt{1 + \frac{x^4}{4} - \frac{1}{2} + \frac{1}{4x^4}} dx \\
 &= \int_1^3 \sqrt{\frac{x^4}{4} + \frac{1}{2} + \frac{1}{4x^4}} dx \\
 &= \int_1^3 \sqrt{\left(\frac{x^2}{2} + \frac{1}{2x^2}\right)^2} dx \\
 &= \int_1^3 \left(\frac{x^2}{2} + \frac{1}{2x^2}\right) dx \\
 &= \left[\frac{x^3}{6} - \frac{1}{2x}\right]_1^3 \\
 &= \boxed{\frac{14}{3}}.
 \end{aligned}$$

13. We have $y' = (x^2 + 1)^{1/2} \cdot 2x = 2x\sqrt{x^2 + 1}$, which is continuous on an interval containing 1 and 4. Therefore the Arc Length Formula applies, and the arc length is

$$\begin{aligned}
 s &= \int_1^4 \sqrt{1^2 + \left(2x\sqrt{x^2 + 1}\right)^2} dx \\
 &= \int_1^4 \sqrt{4x^4 + 4x^2 + 1} dx \\
 &= \int_1^4 \sqrt{(2x^2 + 1)^2} dx \\
 &= \int_1^4 (2x^2 + 1) dx \\
 &= \left[\frac{2}{3}x^3 + x\right]_1^4 \\
 &= \boxed{45}.
 \end{aligned}$$

14. We have $y' = \frac{1}{2}(x^2 + 2)^{1/2} \cdot 2x = x\sqrt{x^2 + 2}$, which is continuous on an interval containing 2 and 4. Therefore the Arc Length Formula applies, and the arc length is

$$\begin{aligned}
 s &= \int_2^4 \sqrt{1^2 + \left(x\sqrt{x^2 + 2}\right)^2} dx \\
 &= \int_2^4 \sqrt{x^4 + 2x^2 + 1} dx \\
 &= \int_2^4 \sqrt{(x^2 + 1)^2} dx \\
 &= \int_2^4 (x^2 + 1) dx \\
 &= \left[\frac{1}{3}x^3 + x \right]_2^4 \\
 &= \boxed{\frac{62}{3}}.
 \end{aligned}$$

15. We have

$$y' = \frac{2}{9}\sqrt{3} \cdot \frac{3}{2}(3x^2 + 1)^{1/2} \cdot 6x = 2\sqrt{3}x\sqrt{3x^2 + 1}.$$

This is continuous on an interval containing -1 and 2 , so the Arc Length Formula applies and the arc length is

$$\begin{aligned}
 s &= \int_{-1}^2 \sqrt{1^2 + \left(2\sqrt{3}x\sqrt{3x^2 + 1}\right)^2} dx \\
 &= \int_{-1}^2 \sqrt{36x^4 + 12x^2 + 1} dx \\
 &= \int_{-1}^2 \sqrt{(6x^2 + 1)^2} dx \\
 &= \int_{-1}^2 (6x^2 + 1) dx \\
 &= [2x^3 + x]_{-1}^2 \\
 &= \boxed{21}.
 \end{aligned}$$

16. We have

$$y' = \frac{3}{2} \left(1 - x^{2/3}\right)^{1/2} \cdot \left(-\frac{2}{3}x^{-1/3}\right) = -x^{-1/3}\sqrt{1 - x^{2/3}}.$$

This is continuous on an interval containing $\frac{1}{8}$ and 1 , so that the Arc Length Formula applies and the arc length is

$$\begin{aligned}
 s &= \int_{1/8}^1 \sqrt{1^2 + \left(-x^{-1/3}\sqrt{1 - x^{2/3}}\right)^2} dx \\
 &= \int_{1/8}^1 \sqrt{x^{-2/3}} dx \\
 &= \int_{1/8}^1 x^{-1/3} dx \\
 &= \left[\frac{3}{2}x^{2/3} \right]_{1/8}^1 \\
 &= \boxed{\frac{9}{8}}.
 \end{aligned}$$

17. Solving for y gives $y = \frac{x^4}{8} + \frac{1}{4x^2}$. Then $y' = \frac{x^3}{2} - \frac{1}{2x^3}$, which is continuous on an interval containing 1 and 2. Therefore the Arc Length Formula applies, and the arc length is

$$\begin{aligned}
 s &= \int_1^2 \sqrt{1^2 + \left(\frac{x^3}{2} - \frac{1}{2x^3}\right)^2} dx \\
 &= \int_1^2 \sqrt{1 + \frac{x^6}{4} - \frac{1}{2} + \frac{1}{4x^6}} dx \\
 &= \int_1^2 \sqrt{\frac{x^6}{4} + \frac{1}{2} + \frac{1}{4x^6}} dx \\
 &= \int_1^2 \sqrt{\left(\frac{x^3}{2} + \frac{1}{2x^3}\right)^2} dx \\
 &= \int_1^2 \left(\frac{x^3}{2} + \frac{1}{2x^3}\right) dx \\
 &= \left[\frac{x^4}{8} - \frac{1}{4x^2}\right]_1^2 \\
 &= \boxed{\frac{33}{16}}.
 \end{aligned}$$

18. Solving for y gives $y^2 = \frac{4}{9}(1+x^2)^3$, so that $y = \frac{2}{3}(1+x^2)^{3/2}$ (since $y \geq 0$). Then $y' = (1+x^2)^{1/2} \cdot 2x = 2x\sqrt{1+x^2}$. This is continuous everywhere, so that the Arc Length Formula applies and the arc length is

$$\begin{aligned}
 s &= \int_0^{2\sqrt{2}} \sqrt{1^2 + \left(2x\sqrt{1+x^2}\right)^2} dx \\
 &= \int_0^{2\sqrt{2}} \sqrt{4x^4 + 4x^2 + 1} dx \\
 &= \int_0^{2\sqrt{2}} \sqrt{(2x^2 + 1)^2} dx \\
 &= \int_0^{2\sqrt{2}} (2x^2 + 1) dx \\
 &= \left[\frac{2}{3}x^3 + x\right]_0^{2\sqrt{2}} \\
 &= \boxed{\frac{38}{3}\sqrt{2}}.
 \end{aligned}$$

19. We get $y' = \frac{1}{\sin x} \cdot (-\cos x) = -\cot x$. This is continuous on an interval containing $\frac{\pi}{6}$ and $\frac{\pi}{3}$, so the Arc Length Formula applies. Using the identity $1 + \cot^2 x = \csc^2 x$, the arc length is

$$\begin{aligned} s &= \int_{\pi/6}^{\pi/3} \sqrt{1^2 + (-\cot x)^2} dx \\ &= \int_{\pi/6}^{\pi/3} \sqrt{1 + \cot^2 x} dx \\ &= \int_{\pi/6}^{\pi/3} \csc x dx \\ &= [\ln |\csc x - \cot x|]_{\pi/6}^{\pi/3} \\ &= \ln \left| \frac{2}{\sqrt{3}} - \frac{1}{\sqrt{3}} \right| - \ln |2 - \sqrt{3}|. \end{aligned}$$

This expression can be simplified to $-\ln(2\sqrt{3} - 3)$.

20. We get $y' = \frac{1}{\cos x} \cdot \sin x = \tan x$. This is continuous on an interval containing $\frac{\pi}{6}$ and $\frac{\pi}{3}$, so the Arc Length Formula applies. Using the identity $1 + \tan^2 x = \sec^2 x$, the arc length is

$$\begin{aligned} s &= \int_{\pi/6}^{\pi/3} \sqrt{1^2 + (\tan x)^2} dx \\ &= \int_{\pi/6}^{\pi/3} \sqrt{1 + \tan^2 x} dx \\ &= \int_{\pi/6}^{\pi/3} \sec x dx \\ &= [\ln |\sec x + \tan x|]_{\pi/6}^{\pi/3} \\ &= \ln |2 + \sqrt{3}| - \ln \left| \frac{2}{\sqrt{3}} + \frac{1}{\sqrt{3}} \right| \\ &= \ln(2 + \sqrt{3}) - \ln(\sqrt{3}) \\ &= \ln \frac{2 + \sqrt{3}}{\sqrt{3}} = \ln \frac{2\sqrt{3} + 3}{3}. \end{aligned}$$

21. Since $y \geq 0$, solving for y gives $y = \frac{1}{2}(x+1)^{3/2}$, so that $y' = \frac{3}{4}\sqrt{x+1}$, which is continuous on an interval containing -1 and 16 . Therefore the Arc Length Formula applies, and the arc length is

$$s = \int_{-1}^{16} \sqrt{1^2 + \left(\frac{3}{4}\sqrt{x+1}\right)^2} dx = \frac{1}{4} \int_{-1}^{16} \sqrt{9x+25} dx.$$

Now use the substitution $u = 9x + 25$, so that $du = 9dx$. Then $x = -1$ corresponds to $u = 16$ and $x = 16$ corresponds to $u = 169$, so we get

$$\frac{1}{4} \int_{-1}^{16} \sqrt{9x+25} dx = \frac{1}{4} \cdot \frac{1}{9} \int_{16}^{169} u^{1/2} du = \frac{1}{36} \left[\frac{2}{3} u^{3/2} \right]_{16}^{169} = \frac{1}{54} (13^3 - 4^3) = \boxed{\frac{79}{2}}.$$

22. The derivative of $x^{3/2} + 8$ is $\frac{3}{2}x^{1/2}$, so that y has a continuous derivative on an interval containing 0 and 4 . Therefore the Arc Length Formula applies, and the arc length is

$$s = \int_0^4 \sqrt{1^2 + \left(\frac{3}{2}x^{1/2}\right)^2} dx = \frac{1}{2} \int_0^4 \sqrt{4+9x} dx = \frac{1}{2} \left[\frac{2}{27} (4+9x)^{3/2} \right]_0^4 = \boxed{\frac{1}{27} (80\sqrt{10} - 8)}.$$

23. Since $y' = \frac{2}{3}x^{-1/3}$ is not continuous (or even defined) at $x = 0$, we try partitioning the y -axis instead. Solving $y = x^{2/3}$ for x gives $x = y^{3/2}$, so that $x' = \frac{3}{2}\sqrt{y}$. Note that this is the same curve as the one we are interested in, just expressed differently, so that it has the same arc length. Now, $x = 0$ corresponds to $y = 0$, and $x = 1$ to $y = 1$. Since $\frac{3}{2}\sqrt{y}$ is continuous on an interval containing 0 and 1, the Arc Length Formula for partitioning along the y -axis applies, and the arc length is

$$s = \int_0^1 \sqrt{1 + \left(\frac{3}{2}\sqrt{y}\right)^2} dy = \frac{1}{2} \int_0^1 \sqrt{4 + 9y} dy.$$

Now substitute $u = 4 + 9y$; then $du = 9 dy$. Further, $y = 0$ corresponds to $u = 4$ while $y = 1$ corresponds to $u = 13$, so we get

$$\frac{1}{2} \int_0^1 \sqrt{4 + 9y} dy = \frac{1}{2} \cdot \frac{1}{9} \int_4^{13} u^{1/2} du = \frac{1}{18} \left[\frac{2}{3} u^{3/2} \right]_4^{13} = \boxed{\frac{1}{27}(13\sqrt{13} - 8)}.$$

24. Since $y = x^{2/3}$ is symmetric about the y -axis, its arc length from $x = -1$ to $x = 0$ is the same as its arc length from $x = 0$ to $x = 1$. But this arc length was just computed in Problem 23 to be

$$\boxed{\frac{1}{27}(13\sqrt{13} - 8)}.$$

25. Since we wish to partition along the y -axis, we solve for x , giving $x = 2y^{3/2} - 1$. (Note that we took the positive square root of $4y^3$ since we have $x \geq -1$.) Then $x' = 3y^{1/2} = 3\sqrt{y}$, which is continuous on an interval containing 0 and 1. Therefore the Arc Length Formula applies, and the arc length is

$$s = \int_0^1 \sqrt{1^2 + (3\sqrt{y})^2} dy = \int_0^1 \sqrt{9y + 1} dy.$$

Now make the substitution $u = 9y + 1$, so that $du = 9 dy$. Then $y = 0$ corresponds to $u = 1$, and $y = 1$ corresponds to $u = 10$, so we get

$$\int_0^1 \sqrt{9y + 1} dy = \frac{1}{9} \int_1^{10} u^{1/2} du = \frac{1}{9} \left[\frac{2}{3} u^{3/2} \right]_1^{10} = \boxed{\frac{2}{27}(10\sqrt{10} - 1)}.$$

26. We get $x' = (y - 5)^{1/2} = \sqrt{y - 5}$, which is continuous on an interval containing 5 and 6, so the Arc Length Formula applies, and the arc length is

$$s = \int_5^6 \sqrt{1^2 + (\sqrt{y - 5})^2} dy = \int_5^6 \sqrt{y - 4} dy = \left[\frac{2}{3} (y - 4)^{3/2} \right]_5^6 = \boxed{\frac{2}{3}(2\sqrt{2} - 1)}.$$

27. (a) We have $y' = 2x$, which is continuous everywhere, so the Arc Length Formula applies and the arc length is

$$s = \int_0^2 \sqrt{1^2 + (2x)^2} dx = \int_0^2 \sqrt{4x^2 + 1} dx.$$

(b) Using technology, this evaluates to $s \approx 4.64678$.

28. We will determine arc length by subdividing along the y -axis.

(a) $x' = 2y$, which is continuous everywhere, so the Arc Length Formula applies and the arc length is

$$s = \int_1^3 \sqrt{1^2 + (2y)^2} dy = \int_1^3 \sqrt{4y^2 + 1} dy.$$

(b) Using technology, this evaluates to $s \approx 8.26815$.

29. (a) $y' = \frac{1}{2}(25 - x^2)^{-1/2} \cdot (-2x) = -x(25 - x^2)^{-1/2}$. This is continuous on an interval containing 0 and 4, so the Arc Length Formula applies, and the arc length is

$$s = \int_0^4 \sqrt{1^2 + (-x(25 - x^2)^{-1/2})^2} dx = \int_0^4 \sqrt{1 + \frac{x^2}{25 - x^2}} dx = \int_0^4 \sqrt{\frac{25}{25 - x^2}} dx.$$

(b) Using technology, this evaluates to $s \approx 4.63648$.

30. We will determine arc length by partitioning along the y -axis.

- (a) $x' = \frac{1}{2}(4 - y^2)^{-1/2} \cdot (-2y) = -y(4 - y^2)^{-1/2}$. This is continuous on an interval containing 0 and 1, so the Arc Length Formula applies, and the arc length is

$$s = \int_0^1 \sqrt{1^2 + (-y(4 - y^2)^{-1/2})^2} dy = \int_0^1 \sqrt{1 + \frac{y^2}{4 - y^2}} dy = \int_0^1 \sqrt{\frac{4}{4 - y^2}} dy.$$

(b) Using technology, this evaluates to $s \approx 1.0472$.

31. (a) $y' = \cos x$, which is continuous everywhere, so the Arc Length Formula applies. The arc length is

$$s = \int_0^{\pi/2} \sqrt{1^2 + (\cos x)^2} dx = \int_0^{\pi/2} \sqrt{1 + \cos^2 x} dx.$$

(b) Using technology, this evaluates to $s \approx 1.9101$.

32. We will determine arc length by partitioning along the y -axis.

- (a) $x' = 1 + \frac{1}{y}$, which is continuous on an interval containing 1 and 4, so the Arc Length Formula applies. The arc length is

$$s = \int_1^4 \sqrt{1^2 + \left(1 + \frac{1}{y}\right)^2} dy = \int_1^4 \sqrt{\frac{1}{y^2} + \frac{2}{y} + 2} dy = \int_1^4 \frac{\sqrt{2y^2 + 2y + 1}}{y} dy.$$

(b) Using technology, this evaluates to $s \approx 5.32324$.

Applications and Extensions

33. The hypocycloid is shown below:

All four arcs are the same (the graph is symmetric in both x and y , since $(-x)^{2/3} = x^{2/3}$ and $(-y)^{2/3} = y^{2/3}$), and the arc in the first quadrant is symmetric about the line $x = y$, so the total arc length is the length of half of that arc, multiplied by 8. The arc in the first quadrant is divided in half at the point where the x -coordinate and the y -coordinate are equal, which is when $2x^{2/3} = a^{2/3}$, or $x = \frac{a}{2^{3/2}}$. So consider the arc from $x = \frac{a}{2^{3/2}}$ to $x = a$ in the first quadrant. Then $x, y \geq 0$, and solving for y gives

$$y = \left(a^{2/3} - x^{2/3}\right)^{3/2},$$

so that

$$y' = \frac{3}{2} \left(a^{2/3} - x^{2/3}\right)^{1/2} \cdot \left(-\frac{2}{3}x^{-1/3}\right) = -x^{-1/3} \left(x^{2/3} - a^{2/3}\right)^{1/2}.$$

Now, y' is continuous on an interval containing $\frac{a}{2^{3/2}}$ and a , so the Arc Length Formula applies and the total length of the hypocycloid is therefore

$$\begin{aligned} s &= 8 \int_{a/(2^{3/2})}^a \sqrt{1^2 + \left(-x^{-1/3} \left(a^{2/3} - x^{2/3}\right)^{1/2}\right)^2} dx \\ &= 8 \int_{a/(2^{3/2})}^a \sqrt{1 + x^{-2/3} \left(a^{2/3} - x^{2/3}\right)} dx \\ &= 8 \int_{a/(2^{3/2})}^a \sqrt{a^{2/3} x^{-2/3}} dx \\ &= 8 \int_{a/(2^{3/2})}^a a^{1/3} x^{-1/3} dx \\ &= 8 \left[\frac{3}{2} a^{1/3} x^{2/3} \right]_{a/(2^{3/2})}^a \\ &= 12 \left(a^{1/3} a^{2/3} - a^{1/3} \cdot \frac{a^{2/3}}{(2^{3/2})^{2/3}} \right) \\ &= 12 \left(a - \frac{a}{2} \right) = 6a. \end{aligned}$$

The arc length of the hypocycloid is $\boxed{6a}$.

34. The curve whose arc length we wish to find is in the first quadrant; there, the curve is $y = \sqrt{x^3} = x^{3/2}$, so that $y' = \frac{3}{2}\sqrt{x}$, which is continuous on an interval containing 1 and 3. Therefore the Arc Length Formula applies, and the arc length is

$$s = \int_1^3 \sqrt{1^2 + \left(\frac{3}{2}\sqrt{x}\right)^2} dx = \frac{1}{2} \int_1^3 \sqrt{4 + 9x} dx = \frac{1}{2} \left[\frac{2}{27} (4 + 9x)^{3/2} \right]_1^3 = \boxed{\frac{1}{27} (31\sqrt{31} - 13\sqrt{13})}.$$

35. The region in question is shown below:

The perimeter of the region is composed of two pieces. The length of the first, along the line $y = x$, can be computed using the Distance Formula: $s = \sqrt{(1-0)^2 + (1-0)^2} = \sqrt{2}$. For the second, we use the Arc Length Formula. If we try to partition along the x -axis, we get $y = x^{2/3}$, so that $y' = \frac{2}{3}x^{-1/3}$, which is not continuous at $x = 0$. So partition instead along the y -axis. Solving the equation for x gives $x = y^{3/2}$, so that $x' = \frac{3}{2}\sqrt{y}$, which is continuous on an interval containing 0 and 1. Therefore the Arc Length Formula applies, and the arc length is

$$s = \int_0^1 \sqrt{1^2 + \left(\frac{3}{2}\sqrt{y}\right)^2} dy = \frac{1}{2} \int_1^3 \sqrt{4 + 9y} dy = \frac{1}{2} \left[\frac{2}{27}(4 + 9y)^{3/2} \right]_1^3 = \frac{1}{27}(31\sqrt{31} - 13\sqrt{13}).$$

So the total arc length is

$$\boxed{\sqrt{2} + \frac{1}{27}(31\sqrt{31} - 13\sqrt{13})}.$$

36. The region in question is shown below:

The perimeter of the region is composed of two pieces. The length of the first, along the line $y = 3(x-1)$, can be computed using the Distance Formula: $s = \sqrt{(2-1)^2 + (3-0)^2} = \sqrt{10}$. For the second, we use the Arc Length Formula. Partitioning along the x -axis, we have $y' = 3 \cdot \frac{3}{2}(x-1)^{1/2} = \frac{9}{2}\sqrt{x-1}$, which is continuous on an interval containing 1 and 3. Therefore the Arc Length Formula applies, and the arc length is

$$s = \int_1^3 \sqrt{1^2 + \left(\frac{9}{2}\sqrt{x-1}\right)^2} dx = \frac{1}{2} \int_1^3 \sqrt{81x - 77} dx = \frac{1}{2} \left[\frac{2}{243}(81x - 77)^{3/2} \right]_1^3 = \frac{1}{243}(166\sqrt{166} - 8).$$

Therefore the total arc length is

$$\boxed{\sqrt{10} + \frac{1}{243}(166\sqrt{166} - 8)}.$$

37. Solving for x gives $x = \frac{y^4+3}{6y} = \frac{y^3}{6} + \frac{1}{2y}$. Then $x' = \frac{y^2}{2} - \frac{1}{2y^2}$, which is differentiable on an interval containing 1 and 2. Therefore the Arc Length Formula applies, and the arc length is

$$\begin{aligned} s &= \int_1^2 \sqrt{1^2 + \left(\frac{y^2}{2} - \frac{1}{2y^2}\right)^2} dy \\ &= \int_1^2 \sqrt{1 + \frac{y^4}{4} - \frac{1}{2} + \frac{1}{4y^4}} dy \\ &= \int_1^2 \sqrt{\frac{y^4}{4} + \frac{1}{2} + \frac{1}{4y^4}} dy \\ &= \int_1^2 \sqrt{\left(\frac{y^2}{2} + \frac{1}{2y^2}\right)^2} dy \\ &= \int_1^2 \left(\frac{y^2}{2} + \frac{1}{2y^2}\right) dy \\ &= \left[\frac{y^3}{6} - \frac{1}{2y}\right]_1^2 \\ &= \boxed{\frac{17}{12}}. \end{aligned}$$

38. We have $y' = \sinh x$, which is continuous everywhere, so that the Arc Length Formula applies. Therefore the arc length is

$$s = \int_0^2 \sqrt{1^2 + (\sinh x)^2} dx = \int_0^2 \sqrt{1 + \sinh^2 x} dx.$$

Since $\cosh^2 x - \sinh^2 x = 1$, we see that $1 + \sinh^2 x = \cosh^2 x$. Since $\cosh x > 0$ everywhere, we get for the arc length

$$s = \int_0^2 \sqrt{\cosh^2 x} dx = \int_0^2 \cosh x dx = [\sinh x]_0^2 = \sinh 2 - \sinh 0 = \boxed{\sinh 2}.$$

39. We have $y' = \frac{1}{\csc x} \cdot (-\cot x \csc x) = -\cot x$, which is continuous on an interval containing $\frac{\pi}{4}$ and $\frac{\pi}{2}$. Therefore the Arc Length Formula applies, and the arc length is

$$s = \int_{\pi/4}^{\pi/2} \sqrt{1^2 + (-\cot x)^2} dx = \int_{\pi/4}^{\pi/2} \sqrt{1 + \cot^2 x} dx.$$

Now use the identity $1 + \cot^2 x = \csc^2 x$; since we are integrating for angles in the first quadrant, $\csc x \geq 0$, so we get for the arc length

$$\begin{aligned} s &= \int_{\pi/4}^{\pi/2} \sqrt{\csc^2 x} dx \\ &= \int_{\pi/4}^{\pi/2} \csc x dx = [\ln |\csc x - \cot x|]_{\pi/4}^{\pi/2} \\ &= \ln 1 - \ln(\sqrt{2} - 1) = \boxed{-\ln(\sqrt{2} - 1)}. \end{aligned}$$

40. Solving the equation for y in the first quadrant (where $y \geq 0$) gives

$$y = b\sqrt{1 - \frac{x^2}{a^2}} = \frac{b}{a}\sqrt{a^2 - x^2}.$$

Then

$$y' = \frac{b}{a} \cdot \frac{1}{2}(a^2 - x^2)^{-1/2} \cdot (-2x) = -\frac{bx}{a\sqrt{a^2 - x^2}}.$$

This is continuous on an interval containing 0 and $\frac{a}{2}$, so the Arc Length Formula applies and we get for the arc length

$$\begin{aligned} s &= \int_0^{a/2} \sqrt{1^2 + \left(-\frac{bx}{a\sqrt{a^2 - x^2}}\right)^2} dx \\ &= \int_0^{a/2} \sqrt{1 + \frac{b^2 x^2}{a^2(a^2 - x^2)}} dx \\ &= \int_0^{a/2} \sqrt{\frac{b^2 x^2 + a^4 - a^2 x^2}{a^2(a^2 - x^2)}} dx \\ &= \int_0^{a/2} \sqrt{\frac{a^4 + x^2(b^2 - a^2)}{a^2(a^2 - x^2)}} dx \\ &= \int_0^{a/2} \sqrt{\frac{a^4 + a^4\left(\frac{x}{a}\right)^2\left(\left(\frac{b}{a}\right)^2 - 1\right)}{a^4\left(1 - \left(\frac{x}{a}\right)^2\right)}} dx \\ &= \int_0^{a/2} \sqrt{\frac{1 + \left(\frac{x}{a}\right)^2\left(\left(\frac{b}{a}\right)^2 - 1\right)}{1 - \left(\frac{x}{a}\right)^2}} dx. \end{aligned}$$

41. The key point here is that partitioning along either axis works except where the circle meets the axes. Where it meets the x -axis, we must partition along the y -axis since the curve has a vertical tangent line, and where it meets the y -axis, we must partition along the x -axis since the curve has a horizontal tangent line. Solving $x^2 + y^2 = 1$ for y gives $y = \pm\sqrt{1 - x^2}$, so that

$$y' = \pm\frac{1}{2}(1 - x^2)^{-1/2} \cdot (-2x) = \pm x(1 - x^2)^{-1/2}.$$

Similarly, if we solve for x and differentiate, we get $x' = \pm y(1 - y^2)^{-1/2}$. So the arc length integrands when partitioning along each axis are

$$\begin{aligned} x\text{-axis : } & \sqrt{1^2 + (\pm x(1 - x^2)^{-1/2})^2} = \sqrt{1 + \frac{x^2}{1 - x^2}} = \frac{1}{\sqrt{1 - x^2}} \\ y\text{-axis : } & \sqrt{1^2 + (\pm y(1 - y^2)^{-1/2})^2} = \sqrt{1 + \frac{y^2}{1 - y^2}} = \frac{1}{\sqrt{1 - y^2}} \end{aligned}$$

Then:

(a) Since P_1 is in quadrant I and P_2 in quadrant II, the only axis crossing occurs at $(0, 1)$, so we can partition along the x -axis for the whole integration, giving

$$s = \int_{x_2}^{x_1} \frac{1}{\sqrt{1 - x^2}} dx.$$

- (b) Since P_1 and P_2 are both in the third quadrant, there are no axis crossings, so we can partition along either axis. Using the y -axis, since $y_1 < y_2$, we get

$$s = \int_{y_1}^{y_2} \frac{1}{\sqrt{1-y^2}} dy.$$

- (c) Since P_1 is in quadrant II and P_2 is in quadrant IV, and we are considering the counterclockwise arc from P_1 to P_2 , there are two axis crossings, at $(-1, 0)$ and at $(0, -1)$. From P_1 to $(-\frac{\sqrt{2}}{2}, -\frac{\sqrt{2}}{2})$ (for example; any other point in the third quadrant would work as well), we can partition along the y -axis, and then from $(-\frac{\sqrt{2}}{2}, -\frac{\sqrt{2}}{2})$ to P_2 we partition along the x -axis. Therefore the arc length is

$$s = \int_{-\sqrt{2}/2}^{y_1} \frac{1}{\sqrt{1-y^2}} dy + \int_{-\sqrt{2}/2}^{x_2} \frac{1}{\sqrt{1-x^2}} dx.$$

42. (a) We want to find the arc length of the curve $y = Ax^{3/2}$ from $y = 0$ to $y = h$. Partitioning along the x -axis, then, we get $y' = \frac{3}{2}Ax^{1/2}$, which is continuous for $x \geq 0$, so the Arc Length Formula applies. Note that $y = h$ gives $h = Ax^{3/2}$, so that $x = (\frac{h}{A})^{2/3}$, and this is the upper bound for integration. Then the arc length is

$$s = \int_0^{(h/A)^{2/3}} \sqrt{1^2 + \left(\frac{3}{2}Ax^{1/2}\right)^2} dx = \boxed{\frac{1}{2} \int_0^{(h/A)^{2/3}} \sqrt{4 + 9A^2x} dx}.$$

- (b) The given numbers mean that $h = 150$ and that $y = h$ corresponds to $x = 250$. Therefore $h = Ax^{3/2}$ means that $150 = A \cdot 250^{3/2}$, so that $A = 150 \cdot 250^{-3/2} \approx 0.0379$.
- (c) Substituting into the formula in part (a), we get

$$\begin{aligned} s &= \frac{1}{2} \int_0^{(h/A)^{2/3}} \sqrt{4 + 9A^2x} dx \approx \frac{1}{2} \int_0^{250} \sqrt{4 + 9 \cdot 0.0379^2 x} dx \\ &\approx \frac{1}{2} \int_0^{250} \sqrt{4 + 0.0129x} dx \approx \boxed{295.099 \text{ m}}. \end{aligned}$$

- (d) If the slope were a straight line, then using the Pythagorean Theorem, its length would be

$$\sqrt{250^2 + 150^2} = \sqrt{85000} \approx 291.55.$$

The length computed in part (c) is slightly longer than the straight-line distance, so it appears reasonable.

43. (a) Since $y' = a \sinh \frac{x}{a} \cdot \frac{1}{a} = \sinh \frac{x}{a}$, and $y'(10) = \frac{3}{4}$, we get $\frac{3}{4} = \sinh \frac{10}{a}$, so that $a = \frac{10}{\sinh^{-1} \frac{3}{4}}$. Now, compute the height of the endpoints above b , the lowest point; this is

$$y - b = a \cosh \frac{10}{a} - a = \frac{10}{\sinh^{-1} \frac{3}{4}} \left(\cosh \sinh^{-1} \frac{3}{4} - 1 \right).$$

Since $\cosh^2 x = 1 + \sinh^2 x$ for all x , we can simplify the above formula as follows:

$$\begin{aligned} \frac{10}{\sinh^{-1} \frac{3}{4}} \left(\cosh \sinh^{-1} \frac{3}{4} - 1 \right) &= \frac{10}{\sinh^{-1} \frac{3}{4}} \left(\sqrt{1 + \sinh^2 \sinh^{-1} \frac{3}{4}} - 1 \right) \\ &= \frac{10}{\sinh^{-1} \frac{3}{4}} \left(\sqrt{1 + \frac{9}{16}} - 1 \right) \\ &= \frac{10}{\sinh^{-1} \frac{3}{4}} \left(\sqrt{\frac{25}{16}} - 1 \right) \\ &= \frac{10}{\sinh^{-1} \frac{3}{4}} \cdot \frac{1}{4} = \frac{5}{2 \sinh^{-1} \frac{3}{4}}. \end{aligned}$$

Therefore the height of the supports is $\boxed{b + \frac{5}{2 \sinh^{-1} \frac{3}{4}}}$.

- (b) We determine the arc length by partitioning along the x -axis. From part (a), we know that $y' = \sinh \frac{x}{a}$, so that the arc length is (using the identity $\cosh^2 x = 1 + \sinh^2 x$ again)

$$\begin{aligned} s &= \int_{-10}^{10} \sqrt{1^2 + \left(\sinh \frac{x}{a}\right)^2} dx \\ &= \int_{-10}^{10} \sqrt{1 + \sinh^2 \frac{x}{a}} dx \\ &= \int_{-10}^{10} \sqrt{\cosh^2 \frac{x}{a}} dx \\ &= \int_{-10}^{10} \cosh \frac{x}{a} dx \\ &= \left[a \sinh \frac{x}{a} \right]_{-10}^{10} \\ &= 2a \sinh \frac{10}{a}. \end{aligned}$$

Now substitute the value of a from part (a), giving

$$s = 2 \cdot \frac{10}{\sinh^{-1} \frac{3}{4}} \sinh \sinh^{-1} \frac{3}{4} = \frac{60}{4 \sinh^{-1} \frac{3}{4}} = \boxed{\frac{15}{\sinh^{-1} \frac{3}{4}} \approx 21.6404 \text{ m}}.$$

44. The length of the rope is the arc length. We have $y' = a \sinh \frac{x}{a} \cdot \frac{1}{a} = \sinh \frac{x}{a}$, so that the arc length is (using the identity $\cosh^2 x = 1 + \sinh^2 x$)

$$\begin{aligned} L &= \int_{-c}^c \sqrt{1^2 + \left(\sinh \frac{x}{a}\right)^2} dx \\ &= \int_{-c}^c \sqrt{1 + \sinh^2 \frac{x}{a}} dx \\ &= \int_{-c}^c \sqrt{\cosh^2 \frac{x}{a}} dx \\ &= \int_{-c}^c \cosh \frac{x}{a} dx \\ &= \left[a \sinh \frac{x}{a} \right]_{-c}^c \\ &= 2a \sinh \frac{c}{a}. \end{aligned}$$

Then since d is the height of the rope when $x = c$, we get

$$(d - b + a)^2 - a^2 = \left(a \cosh \frac{c}{a} + b - a - b + a \right)^2 - a^2 = a^2 \left(\cosh^2 \frac{c}{a} - 1 \right) = a^2 \sinh^2 \frac{c}{a} = \frac{L^2}{4}.$$

Expanding the left-hand side and simplifying gives

$$(d - b)^2 + 2a(d - b) = \frac{L^2}{4}, \text{ so that } a = \frac{\frac{L^2}{4} - (d - b)^2}{2(d - b)} = \frac{L^2 - 4(d - b)^2}{8(d - b)}.$$

(Note that $d \neq b$, so this expression makes sense, since d is the height of the ends of the catenary, while b is its lowest height.)

45. (a) Let the parabola be $h(x) = ax^2 + bx + c$. Since $h(0) = 0$, we must have $c = 0$, so that the equation of motion is $h(x) = ax^2 + bx = x(ax + b)$. Since $h(0) = h(150) = 0$, we see that 150 must be a zero of $ax + b$, so that $h(x) = ax(x - 150) = ax^2 - 150ax$. It follows that $b = -150a$. Finally, $h'(x) = 2ax - 150a$, so that $h'(x) = 0$ when $x = 75$. We are given that $h(75) = 46$, so that

$$46 = h(75) = a \cdot 75 \cdot (75 - 150) = -75^2 a, \text{ so that } a = -\frac{46}{75^2}.$$

Therefore the equation of motion is

$$h(x) = -\frac{46}{75^2}x(x - 150) = \frac{46}{75^2}(150x - x^2).$$

- (b) The total arc length is twice the length of the arc from $x = 0$ to the top of the arc, at $x = -\frac{b}{a}$. Using a CAS to integrate, we get

$$\begin{aligned} s &= 2 \int_0^{-b/a} \sqrt{1^2 + (2ax + b)^2} dx = 2 \int_0^{150} \sqrt{1 + \left(-\frac{92}{75^2}x + \frac{92}{75}\right)^2} dx \\ &= \boxed{2\sqrt{14089} + \frac{5625}{46} \sinh^{-1} \frac{92}{75} \approx 363.704 \text{ m}.} \end{aligned}$$

Challenge Problems

46. This function is not differentiable at $x = 0$. To see this, use the definition of the derivative:

$$\lim_{h \rightarrow 0} \frac{f(h) - f(0)}{h} = \lim_{h \rightarrow 0} \frac{h \sin \frac{1}{h} - 0}{h} = \lim_{h \rightarrow 0} \sin \frac{1}{h}.$$

But as $h \rightarrow 0$, $\frac{1}{h} \rightarrow \infty$, so that $\sin \frac{1}{h}$ oscillates infinitely often between -1 and 1 , so that this limit does not exist. Since it is not differentiable on an interval containing $(-\frac{\pi}{2}, \frac{\pi}{2})$, we cannot apply the Arc Length Formula.

47. (a) The total angle around point O is 360° , and the polygon divides it into 2^n equal angles, each of which must be $\frac{360}{2^n} = \frac{180}{2^{n-1}} = \frac{90}{2^{n-2}}$ degrees. But the dotted ray emanating from O is the perpendicular bisector of the opposite side of an isosceles triangle, so it also bisects its angle. Therefore $\alpha = \frac{1}{2} \cdot \frac{90}{2^{n-2}} = \frac{45^\circ}{2^{n-2}}$.
- (b) The right triangle of which α is one angle has hypotenuse 1. The side opposite α therefore has length $\sin \alpha$. Since there are 2^n sides in the polygon, there are $2 \cdot 2^n = 2^{n+1}$ segments of length $\sin \alpha$, so that the sum of all of these segments has length

$$2^{n+1} \sin \alpha = 2^{n+1} \sin \frac{45^\circ}{2^{n-2}}.$$

- (c) A table showing the value of this expression for several values of n is below. The true circumference of the circle is $2\pi r = 2\pi \approx 6.283185307$:

5	10	50	100	500	1000
6.273096981	6.283175451	6.283185307	6.283185307	6.283185307	6.283185307

48. Note that $a_0 = \frac{\sqrt{2}}{2} = \sin 45^\circ$. Then use the half-angle formula

$$\sin \frac{\theta}{2} = \sqrt{\frac{1 - \cos \theta}{2}} = \sqrt{\frac{1 - \sqrt{1 - \sin^2 \theta}}{2}}.$$

Since we start with $\theta = 45^\circ$, all angles will be in the first quadrant, so we can always take positive square roots. Then

$$a_1 = \sin \frac{45^\circ}{2}, \quad a_2 = \sin \frac{45^\circ}{4}, \quad \dots, \quad a_n = \sin \frac{45^\circ}{2^n}.$$

Then by Problem 47, we know that $2^{n+3} \sin \frac{45^\circ}{2^n} = 2^{n+3} a_n$ is a good approximation to the circumference of the circle, which is 2π . Therefore $2^{n+2} a_n$ is a good approximation to $\frac{1}{2} \cdot 2\pi = \pi$. A table showing the value of $2^{n+2} a_n$ for several values of n is below. The true value is $\pi \approx 3.141592654$:

5	10	50	100	500	1000
3.141277251	3.141592346	3.141592654	3.141592654	3.141592654	3.141592654

The expression approaches π rather rapidly.

49. Since s is as given, with $y = f(x)$ we must have

$$s = e^x - f(x) = \int_0^x \sqrt{1 + (f'(t))^2} dt.$$

Taking the derivative of both sides and using the Fundamental Theorem gives

$$e^x - f'(x) = \sqrt{1 + (f'(x))^2}; \text{ now square both sides to get } e^{2x} - 2e^x f'(x) + (f'(x))^2 = 1 + (f'(x))^2.$$

Cancel the quadratic terms and solve for $f'(x)$, giving

$$f'(x) = \frac{e^{2x} - 1}{2e^x} = \frac{1}{2}(e^x - e^{-x}).$$

Now integrate to get

$$f(x) = \frac{1}{2}(e^x + e^{-x}) + C = \cosh x + C.$$

Since $f(0) = 1$, we get $C = 0$, so that $f(x) = \cosh x$. As a check, compute the arc length of f from 0 to x (use t as a dummy variable):

$$s = \int_0^x \sqrt{1^2 + \sinh^2 t} dt = \int_0^x \sqrt{\cosh^2 t} dt = \int_0^x \cosh t dt = \sinh x - \sinh 0 = \sinh x.$$

But

$$e^x - f(x) = e^x - \cosh x = e^x - \frac{1}{2}(e^x + e^{-x}) = \frac{1}{2}(e^x - e^{-x}) = \sinh x,$$

and the two are equal.

6.6: Work

Concepts and Vocabulary

1. True. See the first sentence of this section.
2. $W = Fx$. See the second sentence of this section.
3. A unit of work is called a *newton-meter*, or *joule*, in SI units and a *foot-pound* in the customary U.S. system of units.
4. The work W done by a continuously varying force $F = F(x)$ acting on an object, which moves the object along a straight line in the direction of F from $x = a$ to $x = b$, is given by the definite integral $\int_a^b F(x) dx$. See subsection 1.
5. A spring is said to be in *equilibrium* when it is neither extended nor compressed. See the discussion in subsection 2 of the text.
6. True. See the discussion of springs in subsection 2.
7. True. See the note in Example 4.
8. True. See the discussion at the end of this section in the text.

Skill Building

9. The work is the integral of the force through the distance, so

$$W = \int_5^{20} (40 - x) dx = \left[40x - \frac{1}{2}x^2 \right]_5^{20} = \boxed{\frac{825}{2} \text{ J}}.$$

10. The work is the integral of the force through the distance, so

$$W = \int_1^2 \frac{1}{x} dx = [\ln x]_1^2 = \boxed{\ln 2 \text{ J}}.$$

11. Following the method of example 1, since the density of the chain is 3 kg/m, and the portion of chain x m below the bridge must be lifted $40 - x$ m, we get (since $g = 9.8 \text{ m/s}^2$)

$$W = 9.8 \int_0^{40} 3(40 - x) dx = 9.8 \left[120x - \frac{3}{2}x^2 \right]_0^{40} = \boxed{23520 \text{ J}}.$$

12. Following the method of Example 1, since the density of the chain is 2 lb/ft, and the portion of chain x ft below the roof must be lifted $120 - x$ feet, we get

$$W = \int_0^{120} 2(120 - x) dx = [240x - x^2]_0^{120} = \boxed{14400 \text{ ft-lbs}}.$$

13. Since the restoring force is -3 N , we have

$$-3 = -k \cdot \frac{1}{4}, \quad \text{so that} \quad k = \boxed{12 \text{ N/m}}.$$

14. Since the restoring force is 6 ft-lb , we have

$$6 = -k \cdot \left(-\frac{1}{2}\right), \quad \text{so that} \quad k = \boxed{12 \text{ lb/ft}}.$$

15. We are stretching the spring 0.6 m beyond equilibrium, so the work done by the spring force is

$$\int_0^{0.6} (-5x) dx = \left[-\frac{5}{2}x^2 \right]_0^{0.6} = \boxed{-0.9 \text{ J}}.$$

16. We are compressing the spring 0.2 m from equilibrium, so the work done by the spring force is

$$\int_0^{-0.2} (-0.3x) dx = [-0.15x^2]_0^{-0.2} = \boxed{-0.006 \text{ J}}.$$

17. Water that is x feet above the bottom of the pool must be lifted $4 - x$ feet. The cross sectional area of the pool at any height is the area of a circle with radius 12 ft, which is 144π . The water at the bottom must be lifted 4 feet, while the water at the top is lifted 0 feet, so the limits of integration are from 0 to 4, and the work performed is

$$\int_0^4 (62.42 \cdot 144\pi \cdot (4 - x)) dx = 8988.48\pi \int_0^4 (4 - x) dx = 8988.48\pi \left[4x - \frac{1}{2}x^2 \right]_0^4 = \boxed{\approx 225905 \text{ ft-lb}}.$$

18. Gasoline that is x meters above the bottom of the tank must be lifted $10 - x$ m. The cross sectional area of the tank at any height is the area of a circle with radius 8, which is 64π . The gasoline at the

bottom must be lifted 10 m, while that at the top is lifted 0 m, so the limits of integration are from 0 to 10, and the work performed is

$$\begin{aligned} 9.8 \int_0^{10} (720 \cdot 64\pi \cdot (10 - x)) \, dx &= 451584\pi \int_0^{10} (10 - x) \, dx \\ &= 451584\pi \left[10x - \frac{1}{2}x^2 \right]_0^{10} = \boxed{\approx 7.093 \times 10^7 \text{ J}}. \end{aligned}$$

19. Each horizontal cross section of the pyramid is a square; the side lengths of this square decrease linearly from 2 at the top to 0 at the bottom, so at a point x meters below the top of the container, the side length is $2 - \frac{2}{5}x$. Therefore the cross sectional area of the slurry at height x is $(2 - \frac{2}{5}x)^2$, and this must be lifted x m. So the work performed (since the container is only filled 4 meters deep) is

$$\begin{aligned} 9.8 \int_1^5 \left(17.9 \cdot \left(2 - \frac{2}{5}x \right)^2 \cdot x \right) \, dx &= 175.42 \int_1^5 \left(4x - \frac{8}{5}x^2 + \frac{4}{25}x^3 \right) \, dx \\ &= 175.42 \left[2x^2 - \frac{8}{15}x^3 + \frac{1}{25}x^4 \right]_1^5 = \boxed{1197.53 \text{ J}}. \end{aligned}$$

20. Each horizontal cross section of the vat is a rectangle; its sides decrease linearly from 2×0.5 at the top to 0×0 at the bottom, so at a point x meters below the top of the vat, the dimensions of the cross section are $(2 - \frac{1}{2}x) \cdot (0.5 - \frac{1}{8}x)$. Therefore the area of this cross section is

$$\left(2 - \frac{1}{2}x \right) \left(\frac{1}{2} - \frac{1}{8}x \right) = 1 - \frac{1}{2}x + \frac{1}{16}x^2.$$

This cross section must be lifted x meters. Finally, the density of olive oil is

$$0.9 \text{ g/cm}^3 \times 0.001 \text{ kg/g} \times 100^3 \text{ cm}^3/\text{m}^3 = 900 \text{ kg/m}^3.$$

The vat is filled to a depth of 2 m, so we must integrate from 2 m below the top to 4 m below the top, and the work is

$$\begin{aligned} 9.8 \int_2^4 \left(900x \left(1 - \frac{1}{2}x + \frac{1}{16}x^2 \right) \right) \, dx &= 8820 \int_2^4 \left(x - \frac{1}{2}x^2 + \frac{1}{16}x^3 \right) \, dx \\ &= 8820 \left[\frac{1}{2}x^2 - \frac{1}{6}x^3 + \frac{1}{64}x^4 \right]_2^4 = \boxed{3675 \text{ J}}. \end{aligned}$$

Applications and Extensions

21. The elevator itself is lifted 400 ft, so this takes $10,000 \times 400 = 4 \times 10^6$ ft-lbs of work. The remaining work is lifting the cables themselves. For each cable, the portion of the cable x feet from the top must be lifted x feet. The cable weighs 0.36 lbs/in, which is $0.36 \times 12 = 4.32$ lbs/ft, so the work involved in lifting all six cables is

$$6 \int_0^{400} 4.32x \, dx = 6 [2.16x^2]_0^{400} = 2.0736 \times 10^6 \text{ ft-lbs}.$$

The total work is the sum of these two, or $\boxed{6.0736 \times 10^6 \text{ ft-lbs}}$.

22. The 15 m of cable must be lowered another 60 m; since the cable's density is 9 kg/m, this takes $15 \times 9 \times 60 \times 9.8 = 79380$ J. The remainder of the work expended is to lower the additional cable. A bit of cable on the spool that ends up x m below the spool must be lowered x m, so the work expended is

$$9.8 \int_0^{60} 9x \, dx = 9.8 \left[\frac{9}{2}x^2 \right]_0^{60} = 158760 \text{ J}.$$

So the total work expended by gravity is $79380 + 158760 = \boxed{238140 \text{ J}}$.

23. Pulling the bucket itself to the top requires lifting a mass of 75 kg through a distance of 10 m, which takes $75 \times 10 \times 9.8 = 7350$ J. The remainder of the work expended is for the chain itself. The mass density of the chain is $\frac{20}{10} = 2$ kg/m, and the portion of the chain x m below the roof must be lifted x m, so the work expended is

$$9.8 \int_0^{10} 2x \, dx = 9.8 [x^2]_0^{10} = 980 \text{ J.}$$

Therefore the total work is $7350 + 980 = \boxed{8330 \text{ J}}$.

24. Pulling the bucket itself to the top requires lifting a mass of 75 kg through a distance of 10 m, which takes $75 \times 10 \times 9.8 = 7350$ J. The remainder of the work expended is for the chain itself. The mass density of the chain is $\frac{15}{10} = 1.5$ kg/m, and the portion of the chain x m below the roof must be lifted x m, so the work expended is

$$9.8 \int_0^{10} 1.5x \, dx = 9.8 [0.75x^2]_0^{10} = 735 \text{ J.}$$

Therefore the total work is $7350 + 735 = \boxed{8085 \text{ J}}$.

25. The force required to extend the spring from 1 m to 3 m, which is 2 m beyond its equilibrium point, is -3 N, so the spring constant is given by $-3 = -k \cdot 2$, and therefore $k = \frac{3}{2}$. Then the work expended to extend it 1 m from equilibrium (to a length of 2 m) is

$$\int_0^1 \left(-\frac{3}{2}\right) x \, dx = -\left[\frac{3}{4}x^2\right]_0^1 = \boxed{-\frac{3}{4} \text{ J}}.$$

26. The force required to compress the spring by $\frac{3}{2}$ m is 10 N, so the spring constant is given by the equation $10 = -k \cdot \left(-\frac{3}{2}\right)$, and therefore $k = \frac{20}{3}$. Then the work expended to compress the spring to a length of 1 m is

$$\int_0^1 \left(-\frac{20}{3}x\right) \, dx = \left[\frac{10}{3}x^2\right]_0^1 = \boxed{-\frac{10}{3} \text{ J}}.$$

27. The force required to extend the spring by 4 ft is 2 lb, so the spring constant is given by $-2 = -k \cdot 4$, and then $k = \frac{1}{2}$. So

$$-9 \text{ ft-lb} = \int_0^x \left(-\frac{1}{2}t\right) \, dt = -\left[\frac{1}{4}t^2\right]_0^x = -\frac{1}{4}x^2 \text{ ft-lb.}$$

Simplifying gives $x^2 = 36$, so that $x = 6$ (since we are extending the spring, we take the positive solution). Therefore the total length of the spring is $6 + 4 = \boxed{10 \text{ ft}}$.

28. The spring constant is $\frac{1}{2}$, from Problem 27, so using the integral from Problem 27, we get

$$-8 \text{ ft-lb} = -\frac{1}{4}x^2 \text{ ft-lb,}$$

so that $x = \sqrt{32} = 4\sqrt{2}$. So the spring is extended $4\sqrt{2}$ ft, for a total length of $\boxed{4 + 4\sqrt{2} \text{ ft}}$.

29. The radius of the cone, which is 4 m at the top and 0 m at the bottom, decreases linearly with height, so at a distance of x m from the top, its radius is $4 - x$ m. Therefore the cross sectional area of the cone x m from the top is $\pi(4 - x)^2 \text{ m}^2$. That cross section must be lifted x m, so that the total work required is

$$\begin{aligned} 9.8 \int_0^4 1000 \cdot x \cdot \pi(4 - x)^2 \, dx &= 9800\pi \int_0^4 x(4 - x)^2 \, dx = 9800\pi \int_0^4 (16x - 8x^2 + x^3) \, dx \\ &= 9800\pi \left[8x^2 - \frac{8}{3}x^3 + \frac{1}{4}x^4\right]_0^4 = \boxed{\frac{627200}{3}\pi \text{ J}}. \end{aligned}$$

30. All the calculations from Problem 29 are still valid, except that the integration goes from 2 to 4 (since the integration variable x is the distance below the top of the tank). Therefore we get for the work

$$9.8 \cdot 1000\pi \left[8x^2 - \frac{8}{3}x^3 + \frac{1}{4}x^4 \right]_2^4 = \boxed{\frac{196000}{3}\pi \text{ J}}.$$

31. To determine the radius of the cross section x m below the top of the bowl, consider the following diagram, which shows a vertical cross section through the center of the bowl:

At a height x m below the top, the radius of the cross section is $\sqrt{16 - x^2}$, so that the area of the cross section at that height is $(16 - x^2)\pi$. That cross section must be lifted x m, so the work performed is

$$9.8 \int_2^4 1000x(16 - x^2)\pi \, dx = 9800\pi \int_2^4 (16x - x^3) \, dx = 9800\pi \left[8x^2 - \frac{1}{4}x^4 \right]_2^4 = \boxed{352800\pi \text{ J}}.$$

32. The area of each cross section is the same as in Problem 31. Now, that cross section must be lifted $x + 2$ m, since we want to lift it 2 m above the top of the tank. The integration bounds are now from 0 to 4, since the tank is full. Then the work performed is

$$\begin{aligned} 9.8 \int_0^4 1000(x + 2)(16 - x^2)\pi \, dx &= 9800\pi \int_0^4 (-x^3 - 2x^2 + 16x + 32) \, dx \\ &= 9800\pi \left[-\frac{1}{4}x^4 - \frac{2}{3}x^3 + 8x^2 + 32x \right]_0^4 = \boxed{\frac{4390400}{3}\pi \text{ J}}. \end{aligned}$$

33. The area of each cross section is 4π , since the tank has a diameter of 4 m. The cross section x m below the top must be lifted x m. We wish to lift only the top half of the water, so the integration bounds are from 0 to 3 and the total work is

$$9.8 \int_0^3 1000x \cdot 4\pi \, dx = 9.8 \int_0^3 4000\pi x \, dx = 9.8 [2000\pi x^2]_0^3 = \boxed{176400\pi \text{ J}}.$$

34. The area of each horizontal cross section is $30 \times 20 = 600 \text{ ft}^2$, and the cross section x ft below the top must be raised x ft. The integration bounds are from 1 to 6 since there is water in the bottom 5 feet of the pool. Therefore the total work is

$$\int_1^6 62.42x \cdot 600 \, dx = [18726x^2]_1^6 = \boxed{655410 \text{ ft-lbs}}.$$

35. The area of each horizontal cross section is $25 \times 15 = 375 \text{ ft}^2$, and the cross section x ft below the top must be raised x ft. The integration bounds are from 1 to 5 since there is water in the bottom 4 feet of the pool. Therefore the total work is

$$\int_1^5 62.42x \cdot 375 \, dx = [11703.8x^2]_1^5 = 280890 \text{ ft-lbs}.$$

Since the motor can do 550 ft-lbs of work per second, the time required to empty the pool is

$$\frac{280890}{550} \text{ s} \approx 511 \text{ s} = \frac{511}{60} \text{ min} \approx \boxed{8.5 \text{ min}}.$$

It takes between 8 and 9 minutes to empty the pool.

36. From the discussion in the text, the work required to move a mass m kg from the surface of the Earth to a distance d meters above the center of the Earth is

$$gRm \left(1 - \frac{R}{R+d} \right) \text{ J},$$

where $g \approx 9.8 \text{ m/s}^2$ is the acceleration due to Earth's gravity and $R \approx 6.37 \times 10^6 \text{ m}$ is the radius of the Earth. So to move a mass of 30 kg a distance of 30 km = 30000 m above the Earth's surface requires

$$9.8 \cdot 6.37 \times 10^6 \cdot 30 \left(1 - \frac{6370000}{6370000 + 30000} \right) \approx \boxed{8.77866 \times 10^6 \text{ J}}.$$

37. From the discussion in the text, the work required to move a mass m kg from the surface of the Earth to a distance d meters above the surface of the Earth is

$$gRm \left(1 - \frac{R}{R+d} \right) \text{ J},$$

where $g \approx 9.8 \text{ m/s}^2$ is the acceleration due to Earth's gravity and $R \approx 6.37 \times 10^6 \text{ m}$ is the radius of the Earth. So to move a mass of 1000 kg a distance of 800 km = 800000 m above the Earth's surface requires

$$9.8 \cdot 6.37 \times 10^6 \cdot 1000 \left(1 - \frac{6370000}{6370000 + 800000} \right) \approx \boxed{6.96524 \times 10^9 \text{ J}}.$$

38. To move the charge from $x = 2a$ to $x = a$, we must apply a force equal to the negative of the electrical force, or $-\frac{m}{x^2}$. Here we are dealing with a unit charge, so $m = 1$, and then the work is

$$\int_{2a}^a \left(-\frac{1}{x^2} \right) dx = \left[\frac{1}{x} \right]_{2a}^a = \boxed{\frac{1}{2a}}.$$

39. Since the water weighs 20 lb at the bottom, and loses a fourth of its weight, it weighs 15 lb at the top. So at a depth x from the top of the well, the weight of the water in the bucket is $15 + 5\frac{x}{25} = 15 + \frac{x}{5}$ lb. Since the bucket weighs 1.5 lb, the total weight being lifted at height x is $16.5 + \frac{x}{5}$ lb. To compute the work, note that there is no need to multiply by x in this integration, since we are lifting this weight "infinitesimally higher", so the expression above is the complete integrand. Another way of looking at this is that in the previous problems, we lifted the cross section all the way to the top, so we needed to multiply by x , the distance to the top, in order to figure out how far to lift it. Here we are lifting it only dx .

$$\int_0^{25} \left(16.5 + \frac{x}{5} \right) dx = \left[16.5x + \frac{1}{10}x^2 \right]_0^{25} = \boxed{475 \text{ ft-lbs}}.$$

40. The force is $F = -300000x$, so the work done is

$$\int_0^{0.1} (-300000x) dx = - \left[150000x^2 \right]_0^{0.1} = \boxed{-1500 \text{ J}}.$$

41. A vertical cross section of the container, with the level of the water source shown, is below:

At height y , a horizontal cross section of the container is a washer with inner radius $\sqrt{y}$ and outer radius 2 (see the figure), so its area is $\pi(2^2 - (\sqrt{y})^2) = (4 - y)\pi$. To lift that water to height y , it must be lifted $y + 2$ units since the source is 2 units below the x -axis. Finally, the container is bounded by $x = \pm 2$, so by $y = 2^2 = 4$. Therefore the total work performed is

$$\int_0^4 (y + 2)(4 - y)\pi \, dy = \pi \int_0^4 (-y^2 + 2y + 8) \, dy = \pi \left[-\frac{1}{3}y^3 + y^2 + 8y \right]_0^4 = \boxed{\frac{80}{3}\pi}.$$

42. (a) The force at 0.1 m is $-100 \cdot (-0.1) = 10$ N; at 0.2 m it is $-100 \cdot (-0.2) = 20$ N; and at 0.4 m it is $-100 \cdot (-0.4) = 4$ N.
- (b) The work is given by the integral of $100x$ over the corresponding intervals:

$$\begin{aligned} \int_0^{0.1} (-100x) \, dx &= -[50x^2]_0^{0.1} = -0.5 \text{ J} \\ \int_0^{0.2} (-100x) \, dx &= -[50x^2]_0^{0.2} = -2.0 \text{ J} \\ \int_0^{0.4} (-100x) \, dx &= -[50x^2]_0^{0.4} = -8.0 \text{ J}. \end{aligned}$$

43. An end-on view of the tank is:

- (a) At a height x m from the bottom of the tank, the width of the cross section shown is

$$2\sqrt{4 - (2 - x)^2} = 2\sqrt{4 - (4 - 4x + x^2)} = 2\sqrt{4x - x^2} \text{ m},$$

so the area of the cross sectional layer is (since the tank is 6 m long)

$$2\sqrt{4x - x^2} \cdot 6 = 12\sqrt{4x - x^2} \text{ m}^2.$$

That cross section must be lifted $2 - x + 2 = 4 - x$ m, so the work required is

$$9.8 \cdot 820 \int_0^2 (4 - x) \cdot 12\sqrt{4x - x^2} dx = 96432 \int_0^2 (4 - x)\sqrt{4x - x^2} dx.$$

- (b) Using technology, we get

$$96432 \int_0^2 (4 - x)\sqrt{4x - x^2} dx \approx 863052 \text{ J}.$$

Challenge Problems

44. (a) Substituting into $W = \int_{V_1}^{V_2} p dV$ gives

$$W = \int_{V_1}^{V_2} \frac{nRT}{V} dV = nRT [\ln V]_{V_1}^{V_2} = \boxed{nRT \ln \frac{V_2}{V_1}}.$$

- (b) Again substituting into $W = \int_{V_1}^{V_2} p dV$ gives (since $\gamma \neq 1$)

$$W = \int_{V_1}^{V_2} \frac{K}{V^\gamma} dV = K \left[\frac{1}{1 - \gamma} V^{1-\gamma} \right]_{V_1}^{V_2} = \boxed{\frac{K}{1 - \gamma} \left(\frac{1}{V_2^{\gamma-1}} - \frac{1}{V_1^{\gamma-1}} \right)}.$$

45. Since the volume is given in cubic feet, and we want cubic inches, we multiply by $12^3 = 1728$ to get 3456 in^3 for the current volume and 6912 in^3 for the desired volume. Since $PV^{1.4} = c$, and $P = 100$ when $V = 3456 \text{ in}^3$, we get $100 \cdot 3456^{1.4} = c$, or $c \approx 8.995 \times 10^6$. Then since we are doubling the volume from 3456 to 6912, the work done is

$$\begin{aligned} W &= \int_{3456}^{6912} P dV \approx \int_{3456}^{6912} \frac{8.995 \times 10^6}{V^{1.4}} dV = 8.995 \times 10^6 \int_{3456}^{6912} V^{-1.4} dV \\ &= 8.995 \times 10^6 \left[-\frac{1}{0.4} V^{-0.4} \right]_{3456}^{6912} \approx 209209 \text{ in-lb}. \end{aligned}$$

46. The work is

$$W = \int_{2.4}^{4.6} P dV = \int_{2.4}^{4.6} \frac{120}{V^{1.2}} dV = 120 \left[-\frac{1}{0.2} V^{-0.2} \right]_{2.4}^{4.6} = 600 \left(\frac{1}{2.4^{0.2}} - \frac{1}{4.6^{0.2}} \right) \approx 61.45 \text{ in-lb}.$$

6.7: Hydrostatic Pressure and Force

Concepts and Vocabulary

1. Pressure is defined as the *force* exerted per unit area.
2. True. The pressure is ρgh , where h is the depth of the plate.
3. (b), Pascal, is correct. See Table 2.
4. True. See the discussion following Table 2.

Skill Building

5. At each height (y -coordinate), the depth of the water above that height is $5 - y$, so the force on a slice at that height is $3\rho g(5 - y)\Delta y$. Therefore the total force is the integral over the possible slices, or

$$\int_0^5 3\rho g(5 - y) dy = 3\rho g \left[5y - \frac{1}{2}y^2 \right]_0^5 = \frac{75}{2}\rho g.$$

Using SI units, we have $\rho g = 9800$, so we get $\frac{75}{2} \cdot 9800 = \boxed{367500 \text{ N}}$.

6. At each height (y -coordinate), the depth of the water above that height is $-y$. At that height, the coordinates of the two edges of the end of the container are, using the Pythagorean Theorem, $\pm\sqrt{4 - y^2}$. So the force on a slice at that height is $2\sqrt{4 - y^2} \cdot \rho g(-y)\Delta y$. Therefore the total force is

$$\int_{-2}^0 2\sqrt{4 - y^2} \cdot \rho g(-y) dy = -2\rho g \int_{-2}^0 y\sqrt{4 - y^2} dy.$$

Make the substitution $u = 4 - y^2$, so that $du = -2y dy$. Then $y = -2$ corresponds to $u = 0$, and $y = 0$ to $u = 4$, so we get

$$-2\rho g \int_{-2}^0 y\sqrt{4 - y^2} dy = -2\rho g \cdot \left(-\frac{1}{2}\right) \int_0^4 u^{1/2} du = \rho g \left[\frac{2}{3}u^{3/2} \right]_0^4 = \frac{16}{3}\rho g.$$

Using SI units, we have $\rho g = 9800$, so we get $\frac{16}{3} \cdot 9800 = \boxed{\frac{156800}{3} \approx 52266.7 \text{ N}}$.

7. Assuming that the diagonal lines make the same angle with the x -axis, we get the following diagram of the end of the container:

The diagonal line on the left passes through $(2, 0)$ and $(0, 1)$, so it has equation

$$y - 1 = \frac{1 - 0}{0 - 2}(x - 0) = -\frac{1}{2}x, \quad \text{or} \quad y = 1 - \frac{1}{2}x, \quad \text{or} \quad x = 2 - 2y.$$

The diagonal line on the right passes through $(4, 0)$ and $(6, 1)$, so it has equation

$$y = \frac{1 - 0}{6 - 4}(x - 4), \quad \text{or} \quad y = \frac{1}{2}x - 2, \quad \text{or} \quad x = 4 + 2y.$$

At a height y , the distance below the surface of the water is $1 - y$, so the force on a slice at that height is

$$\rho g(1 - y)((4 + 2y) - (2 - 2y)) = \rho g(1 - y)(2 + 4y) = \rho g(-4y^2 + 2y + 2).$$

Therefore the total force on the plate is

$$\int_0^1 \rho g(-4y^2 + 2y + 2) dy = \rho g \left[-\frac{4}{3}y^3 + y^2 + 2y \right]_0^1 = \frac{5}{3}\rho g = \boxed{\frac{49000}{3} \approx 16333.3 \text{ N}}.$$

8. The diagonal side of the container passes through the points $(3, 0)$ and $(0, 4)$, so its equation is given by $4x + 3y = 12$, or $x = 3 - \frac{3}{4}y$. At a given y -coordinate, a cross section is $4 - y$ feet below the surface

of the water. Solving $4x + 3y = 12$ for x , we see that the width of that cross section is $x = 3 - \frac{3}{4}y$. Then the total force on the end of the container is

$$\begin{aligned} \int_0^4 \rho g(4-y) \left(3 - \frac{3}{4}y\right) dy &= \rho g \int_0^4 \left(12 - 6y + \frac{3}{4}y^2\right) dy \\ &= \rho g \left[12y - 3y^2 + \frac{1}{4}y^3\right]_0^4 = 16\rho g = \boxed{1000 \text{ lbs}}. \end{aligned}$$

9. At any depth, the width of the plate is 2 m, so the force on a cross section at height y is $2\rho g y \Delta y$. Therefore the total force on the plate is

$$\int_0^6 2\rho g y dy = [\rho g y^2]_0^6 = 36\rho g = \boxed{352800 \text{ N}}.$$

10. The analysis in the solution to Problem 9 is still valid; the only difference is that the integral goes from $y = 1$ to $y = 7$, since the plate is suspended 1 m below the water surface. Therefore the total force on the plate is

$$\int_1^7 2\rho g y dy = [\rho g y^2]_1^7 = 48\rho g = \boxed{470400 \text{ N}}.$$

Applications and Extensions

11. At any depth, the width of the pool is 20 ft. Therefore the force on the short side of the pool is (since the pool is 6 ft deep)

$$\int_0^6 \rho g 20y dy = 62.5 [10y^2]_0^6 = \boxed{22500 \text{ lbs}}.$$

12. The long side of the pool is 30 ft long, so, since the pool is again 6 ft deep, the total force is

$$\int_0^6 \rho g 30y dy = 62.5 [15y^2]_0^6 = \boxed{33750 \text{ lbs}}.$$

13. Place the trapezoid on a Cartesian grid:

Then the equations of the two diagonal lines are:

$$\begin{aligned} y - 0 &= \frac{0 - 2}{2 - 0}(x - 2) & \text{or} & & y &= 2 - x & \text{or} & & x &= 2 - y \\ y - 0 &= \frac{0 - 2}{3 - 5}(x - 3) & \text{or} & & y &= x - 3 & \text{or} & & x &= y + 3. \end{aligned}$$

So at any height y , the height of the water above a slice at that point is $1 - y$ (since the trough is filled only to a depth of 1 m), and the width of the slice is $(y + 3) - (2 - y) = 2y + 1$, so the force on the end of the trough is

$$\begin{aligned} \int_0^1 \rho g(1-y)(2y+1) dy &= \rho g \int_0^1 (-2y^2 + y + 1) dy = \rho g \left[-\frac{2}{3}y^3 + \frac{1}{2}y^2 + y\right]_0^1 \\ &= 9800 \cdot \frac{5}{6} = \boxed{\frac{24500}{3} \approx 8166.67 \text{ N}}. \end{aligned}$$

14. Placing the bottom vertex of the equilateral triangle at the origin, we get the following picture:

Each of the diagonal lines makes an angle of 60° with the x -axis, so their equations are $\frac{y}{x} = \tan 60^\circ$, or $x = \frac{1}{\sqrt{3}}y$ and $\frac{y}{x} = \tan 120^\circ$, or $x = -\frac{1}{\sqrt{3}}y$. So at a height of y above the bottom the width of the trough is $\frac{1}{\sqrt{3}}y - \left(-\frac{1}{\sqrt{3}}y\right) = \frac{2}{\sqrt{3}}y$. Since the equilateral triangle is 2 m on the side, its height is $\sqrt{3}$, so that a cross section at y is $\sqrt{3} - y$ m below the surface. Therefore the force is

$$\int_0^{\sqrt{3}} \rho g(\sqrt{3} - y) \left(\frac{2}{\sqrt{3}}y\right) dy = \rho g \int_0^{\sqrt{3}} \left(-\frac{2}{\sqrt{3}}y^2 + 2y\right) dy = \rho g \left[-\frac{2}{3\sqrt{3}}y^3 + y^2\right]_0^{\sqrt{3}} = 1\rho g = \boxed{9800 \text{ N}}.$$

15. With the origin at the dot in the diagram, water at a given value of y has width $2\sqrt{4 - y^2}$, since the left edge of the trough will be at $x = -\sqrt{4 - y^2}$ and the right edge will be at $\sqrt{4 - y^2}$. Since the trough is filled, water at a given value of y is at a depth of $-y$ m. So the total force is

$$\int_{-2}^0 \rho g(-y)2\sqrt{4 - y^2} dy = \rho g \int_{-2}^0 (-2y\sqrt{4 - y^2}) dy.$$

Now make the substitution $u = 4 - y^2$, so that $du = -2y dy$. Then $y = -2$ corresponds to $u = 0$, and $y = 0$ to $u = 4$, so we get

$$\rho g \int_{-2}^0 (-2y\sqrt{4 - y^2}) dy = \rho g \int_0^4 u^{1/2} du = \rho g \left[\frac{2}{3}u^{3/2}\right]_0^4 = \frac{16}{3}\rho g \approx \boxed{52266 \text{ N}}.$$

16. The face of the floodgate is shown below:

The diagonal lines have slopes $-\frac{1}{0.75} = -\frac{4}{3}$ and $\frac{1}{0.75} = \frac{4}{3}$, so their equations are $x = -\frac{3}{4}y$ and $x = \frac{3}{4}y$. Therefore for a given value of y , the width of a cross section of the floodgate is $\frac{3}{4}y - (-\frac{3}{4}y) = \frac{3}{2}y$, and this cross section is $1 - y$ m below the surface. Then the total force is

$$\int_0^1 \rho g(1 - y) \left(\frac{3}{2}y \right) dy = \rho g \int_0^1 \left(\frac{3}{2}y - \frac{3}{2}y^2 \right) dy = \rho g \left[\frac{3}{4}y^2 - \frac{1}{2}y^3 \right]_0^1 = \boxed{2450 \text{ lbs}}.$$

17. Placing the origin at the center of the bottom of the dam, the face of the dam is shown below:

The two diagonal lines have equations

$$\begin{aligned} y - 0 &= \frac{60 - 0}{-100 - (-75)}(x - (-75)) \quad \text{or} \quad y = -\frac{12}{5}(x + 75) \quad \text{or} \quad y = -\frac{12}{5}x - 180 \\ y - 0 &= \frac{60 - 0}{100 - 75}(x - 75) \quad \text{or} \quad y = \frac{12}{5}(x - 75) \quad \text{or} \quad y = \frac{12}{5}x - 180. \end{aligned}$$

Solving for x gives

$$x = -\frac{5}{12}y - 75 \quad \text{or} \quad x = \frac{5}{12}y + 75.$$

Therefore the width of a cross section at height y is

$$\left(\frac{5}{12}y + 75 \right) - \left(-\frac{5}{12}y - 75 \right) = \frac{5}{6}y + 150,$$

and such a cross section lies $60 - y$ m below the surface. Then the total force is

$$\begin{aligned} \int_0^{60} \rho g(60 - y) \left(\frac{5}{6}y + 150 \right) dy &= \rho g \int_0^{60} \left(9000 - 100y - \frac{5}{6}y^2 \right) dy \\ &= \rho g \left[9000y - 50y^2 - \frac{5}{18}y^3 \right]_0^{60} = \boxed{2.94 \times 10^9 \text{ N}}. \end{aligned}$$

18. Placing the origin at the center of one end of the tank with the positive y -axis pointing down, the face of the tank is shown below:

At a given depth y , the distance across that end of the tank is $2\sqrt{16 - y^2}$, and that cross section lies y ft below the surface. Therefore the total force is

$$\int_0^4 \rho g y \cdot 2\sqrt{16 - y^2} dy = 2\rho g \int_0^4 y\sqrt{16 - y^2} dy.$$

Now use the substitution $u = 16 - y^2$, so that $du = -2y dy$. Then $y = 0$ corresponds to $u = 16$, while $y = 4$ corresponds to $u = 0$, so we get

$$2\rho g \int_0^4 y\sqrt{16 - y^2} dy = 2\rho g \cdot \left(-\frac{1}{2}\right) \int_{16}^0 u^{1/2} dy = -\rho g \left[\frac{2}{3}u^{3/2}\right]_{16}^0 = \frac{128}{3}\rho g = 60 \cdot \frac{128}{3} = \boxed{2560 \text{ lbs}}.$$

19. Place the origin at the center of the viewing plate; then the situation is shown below:

The equation of the viewing plate is $x^2 + y^2 = 1$, so at any y -coordinate, the width of a cross section of the plate is $2\sqrt{1 - y^2}$ (see the figure), and that cross section is $5 - y$ m below the water surface. (Note that if $y < 0$, as drawn, then $5 - y > 5$, which makes sense since this part of the plate is *more* than 5 m below the surface.) Therefore the total force is

$$\int_{-1}^1 \rho g (5 - y) \cdot 2\sqrt{1 - y^2} dy$$

Evaluating numerically, with $\rho g = 1025 \cdot 9.8$, gives $5\rho g\pi \boxed{\approx 157,786 \text{ N}}$.

20. Place the origin at the center of the viewing plate; then the situation is shown below:

The equation of the viewing plate is $x^4 + y^4 = 1$, so at any y -coordinate, the width of a cross section of the plate is $2\sqrt[4]{1-y^4}$ (see the figure), and that cross section is $5-y$ m below the water surface. (Note that if $y < 0$, as drawn, then $5-y > 5$, which makes sense since this part of the plate is *more* than 5 m below the surface.) Therefore the total force is (evaluating numerically, with $\rho g = 1025 \cdot 9.8$)

$$\int_{-1}^1 \rho g(5-y) \cdot 2\sqrt[4]{1-y^4} dy \approx 18.5407 \rho g \boxed{\approx 186,241 \text{ N}}.$$

21. Placing the origin at the center of one end of the tank with the positive y -axis pointing down, the face of the tank is shown below:

Since the tank's radius is 0.25 m, it is half-full. At a given y -coordinate (depth), the width of the cross section of that end is $2\sqrt{0.25^2 - y^2}$, and the cross section lies y m below the surface. So the total force is

$$\int_0^{0.25} \rho g y \cdot 2\sqrt{0.25^2 - y^2} dy$$

Now use the substitution $u = 0.25^2 - y^2$, so that $du = -2y dy$. Then $y = 0$ corresponds to $u = 0.25^2$, while $y = 0.25$ corresponds to $y = 0$, and we get

$$\begin{aligned} \int_0^{0.25} \rho g y \cdot 2\sqrt{0.25^2 - y^2} dy &= -\rho g \int_{0.25^2}^0 u^{1/2} du = -\rho g \left[\frac{2}{3} u^{3/2} \right]_{0.25^2}^0 = \frac{2}{3} \rho g \cdot 0.25^3 \\ &= \frac{2}{3} \cdot 690 \cdot 9.8 \cdot 0.015625 = \boxed{70.4375 \text{ N}}. \end{aligned}$$

6.8: Center of Mass; Centroid; the Pappus Theorem

Concepts and Vocabulary

1. (c), center of mass, is correct. See the first few sentences of this chapter.
2. (c), md , is correct. See the discussion in subsection 1.
3. True. See the discussion in subsection 2.
4. (a) is correct; see Example 4.
5. False. See Example 5 for one instance where it does not.
6. (a) is correct. See the discussion in subsection 2.

Skill Building

7. The center of mass is

$$\bar{x} = \frac{\sum_{i=1}^2 m_i x_i}{\sum_{i=1}^2 m_i} = \frac{20 \cdot 4 + 50 \cdot 10}{20 + 50} = \boxed{\frac{58}{7}}.$$

8. The center of mass is

$$\bar{x} = \frac{\sum_{i=1}^2 m_i x_i}{\sum_{i=1}^2 m_i} = \frac{10 \cdot (-2) + 3 \cdot 3}{10 + 3} = \boxed{-\frac{11}{13}}.$$

9. The center of mass is

$$\bar{x} = \frac{\sum_{i=1}^4 m_i x_i}{\sum_{i=1}^4 m_i} = \frac{4 \cdot (-1) + 3 \cdot 2 + 3 \cdot 4 + 5 \cdot 3}{4 + 3 + 3 + 5} = \boxed{\frac{29}{15}}.$$

10. The center of mass is

$$\bar{x} = \frac{\sum_{i=1}^4 m_i x_i}{\sum_{i=1}^4 m_i} = \frac{7 \cdot 6 + 3 \cdot (-2) + 2 \cdot (-4) + 4 \cdot (-1)}{7 + 3 + 2 + 4} = \frac{24}{16} = \boxed{\frac{3}{2}}.$$

11. The moments are

$$M_y = \sum_{i=1}^3 m_i x_i = 4 \cdot 0 + 8 \cdot 2 + 1 \cdot 4 = 20$$

$$M_x = \sum_{i=1}^3 m_i y_i = 4 \cdot 2 + 8 \cdot 1 + 1 \cdot 8 = 24$$

and the mass is $M = 4 + 8 + 1 = 13$, so that

$$(\bar{x}, \bar{y}) = \left(\frac{M_y}{M}, \frac{M_x}{M} \right) = \boxed{\left(\frac{20}{13}, \frac{24}{13} \right)}.$$

12. The moments are

$$M_y = \sum_{i=1}^3 m_i x_i = 6 \cdot (-1) + 2 \cdot 12 + 10 \cdot (-1) = 8$$

$$M_x = \sum_{i=1}^3 m_i y_i = 6 \cdot (-1) + 2 \cdot 6 + 10 \cdot (-2) = -14$$

and the mass is $M = 6 + 2 + 10 = 18$, so that

$$(\bar{x}, \bar{y}) = \left(\frac{M_y}{M}, \frac{M_x}{M} \right) = \left(\frac{8}{18}, -\frac{14}{18} \right) = \boxed{\left(\frac{4}{9}, -\frac{7}{9} \right)}.$$

13. The moments are

$$M_y = \sum_{i=1}^4 m_i x_i = 4 \cdot (-1) + 3 \cdot 2 + 3 \cdot 4 + 5 \cdot 3 = 29$$

$$M_x = \sum_{i=1}^4 m_i y_i = 4 \cdot 2 + 3 \cdot 3 + 3 \cdot 5 + 5 \cdot 6 = 62$$

and the mass is $M = 4 + 3 + 3 + 5 = 15$, so that

$$(\bar{x}, \bar{y}) = \left(\frac{M_y}{M}, \frac{M_x}{M} \right) = \boxed{\left(\frac{29}{15}, \frac{62}{15} \right)}.$$

14. The moments are

$$M_y = \sum_{i=1}^4 m_i x_i = 8 \cdot (-4) + 6 \cdot 0 + 3 \cdot 6 + 5 \cdot (-3) = -29$$

$$M_x = \sum_{i=1}^4 m_i y_i = 8 \cdot 4 + 6 \cdot 5 + 3 \cdot 4 + 5 \cdot (-5) = 49$$

and the mass is $M = 8 + 6 + 3 + 5 = 22$, so that

$$(\bar{x}, \bar{y}) = \left(\frac{M_y}{M}, \frac{M_x}{M} \right) = \left(-\frac{29}{22}, \frac{49}{22} \right).$$

15. The lamina is shown below:

Let the mass density of the lamina be ρ . Then the mass of the lamina is

$$M = \int_{-1}^2 \rho(2x + 3) dx = \rho [x^2 + 3x]_{-1}^2 = 12\rho,$$

and the moments are

$$M_y = \rho \int_{-1}^2 x(2x + 3) dx = \rho \int_{-1}^2 (2x^2 + 3x) dx = \rho \left[\frac{2}{3}x^3 + \frac{3}{2}x^2 \right]_{-1}^2 = \frac{21}{2}\rho$$

$$M_x = \frac{1}{2}\rho \int_{-1}^2 (2x + 3)^2 dx = \frac{1}{2}\rho \left[\frac{1}{6}(2x + 3)^3 \right]_{-1}^2 = \frac{342}{12}\rho = \frac{57}{2}\rho.$$

Therefore the centroid is

$$(\bar{x}, \bar{y}) = \left(\frac{M_y}{M}, \frac{M_x}{M} \right) = \left(\frac{(21/2)\rho}{12\rho}, \frac{(57/2)\rho}{12\rho} \right) = \left(\frac{21}{2 \cdot 12}, \frac{57}{2 \cdot 12} \right) = \left(\frac{7}{8}, \frac{19}{8} \right).$$

16. The lamina is shown below:

Let the mass density of the lamina be ρ . Then the mass of the lamina is

$$M = \rho \int_{-1}^3 \frac{3-x}{2} dx = \rho \int_{-1}^3 \left(\frac{3}{2} - \frac{1}{2}x \right) dx = \rho \left[\frac{3}{2}x - \frac{1}{4}x^2 \right]_{-1}^3 = 4\rho$$

and the moments are

$$M_y = \rho \int_{-1}^3 x \cdot \frac{3-x}{2} dx = \rho \int_{-1}^3 \left(\frac{3}{2}x - \frac{1}{2}x^2 \right) dx = \rho \left[\frac{3}{4}x^2 - \frac{1}{6}x^3 \right]_{-1}^3 = \frac{4}{3}\rho$$

$$M_x = \frac{1}{2}\rho \int_{-1}^3 \left(\frac{3-x}{2} \right)^2 dx = \frac{1}{8}\rho \int_{-1}^3 (3-x)^2 dx = \frac{1}{8}\rho \left[-\frac{1}{3}(3-x)^3 \right]_{-1}^3 = \frac{8}{3}\rho.$$

Therefore the centroid is

$$(\bar{x}, \bar{y}) = \left(\frac{M_y}{M}, \frac{M_x}{M} \right) = \left(\frac{(4/3)\rho}{4\rho}, \frac{(8/3)\rho}{4\rho} \right) = \left(\frac{4}{3 \cdot 4}, \frac{8}{3 \cdot 4} \right) = \boxed{\left(\frac{1}{3}, \frac{2}{3} \right)}.$$

17. The lamina is shown below:

Let the mass density of the lamina be ρ . Then the mass of the lamina is

$$M = \rho \int_0^3 x^2 dx = \rho \left[\frac{1}{3}x^3 \right]_0^3 = 9\rho$$

and the moments are

$$M_y = \rho \int_0^3 x \cdot x^2 dx = \rho \int_0^3 x^3 dx = \rho \left[\frac{1}{4}x^4 \right]_0^3 = \frac{81}{4}\rho$$

$$M_x = \frac{1}{2}\rho \int_0^3 (x^2)^2 dx = \frac{1}{2}\rho \int_0^3 x^4 dx = \frac{1}{2}\rho \left[\frac{1}{5}x^5 \right]_0^3 = \frac{243}{10}\rho.$$

Therefore the centroid is

$$(\bar{x}, \bar{y}) = \left(\frac{M_y}{M}, \frac{M_x}{M} \right) = \left(\frac{(81/4)\rho}{9\rho}, \frac{(243/10)\rho}{9\rho} \right) = \left(\frac{81}{4 \cdot 9}, \frac{243}{10 \cdot 9} \right) = \boxed{\left(\frac{9}{4}, \frac{27}{10} \right)}.$$

18. The lamina is shown below:

Let the mass density of the lamina be ρ . Then the mass of the lamina is

$$M = \rho \int_0^2 x^3 dx = \rho \left[\frac{1}{4} x^4 \right]_0^2 = 4\rho$$

and the moments are

$$\begin{aligned} M_y &= \rho \int_0^2 x \cdot x^3 dx = \rho \int_0^2 x^4 dx = \rho \left[\frac{1}{5} x^5 \right]_0^2 = \frac{32}{5} \rho \\ M_x &= \frac{1}{2} \rho \int_0^2 (x^3)^2 dx = \frac{1}{2} \rho \int_0^2 x^6 dx = \frac{1}{2} \rho \left[\frac{1}{7} x^7 \right]_0^2 = \frac{64}{7} \rho. \end{aligned}$$

Therefore the centroid is

$$(\bar{x}, \bar{y}) = \left(\frac{M_y}{M}, \frac{M_x}{M} \right) = \left(\frac{(32/5)\rho}{4\rho}, \frac{(64/7)\rho}{4\rho} \right) = \left(\frac{32}{5 \cdot 4}, \frac{64}{7 \cdot 4} \right) = \boxed{\left(\frac{8}{5}, \frac{16}{7} \right)}.$$

19. The lamina is shown below:

Let the mass density of the lamina be ρ . Then the mass of the lamina is

$$M = \rho \int_0^4 (4x - x^2) dx = \rho \left[2x^2 - \frac{1}{3} x^3 \right]_0^4 = \frac{32}{3} \rho$$

and the moments are

$$\begin{aligned} M_y &= \rho \int_0^4 x \cdot (4x - x^2) dx = \rho \int_0^4 (4x^2 - x^3) dx = \rho \left[\frac{4}{3} x^3 - \frac{1}{4} x^4 \right]_0^4 = \frac{64}{3} \rho \\ M_x &= \frac{1}{2} \rho \int_0^4 (4x - x^2)^2 dx = \frac{1}{2} \rho \int_0^4 (16x^2 - 8x^3 + x^4) dx = \frac{1}{2} \rho \left[\frac{16}{3} x^3 - 2x^4 + \frac{1}{5} x^5 \right]_0^4 = \frac{256}{15} \rho. \end{aligned}$$

Therefore the centroid is

$$(\bar{x}, \bar{y}) = \left(\frac{M_y}{M}, \frac{M_x}{M} \right) = \left(\frac{(64/3)\rho}{(32/3)\rho}, \frac{(256/15)\rho}{(32/3)\rho} \right) = \left(2, \frac{256 \cdot 3}{32 \cdot 15} \right) = \boxed{\left(2, \frac{8}{5} \right)}.$$

20. The lamina is shown below:

Let the mass density of the lamina be ρ . Then the mass of the lamina is

$$M = \rho \int_0^4 (x^2 + x + 1) dx = \rho \left[\frac{1}{3}x^3 + \frac{1}{2}x^2 + x \right]_0^4 = \frac{100}{3}$$

and the moments are

$$M_y = \rho \int_0^4 x \cdot (x^2 + x + 1) dx = \rho \int_0^4 (x^3 + x^2 + x) dx = \rho \left[\frac{1}{4}x^4 + \frac{1}{3}x^3 + \frac{1}{2}x^2 \right]_0^4 = \frac{280}{3}\rho$$

$$\begin{aligned} M_x &= \frac{1}{2}\rho \int_0^4 (x^2 + x + 1)^2 dx = \frac{1}{2}\rho \int_0^4 (x^4 + 2x^3 + 3x^2 + 2x + 1) dx \\ &= \frac{1}{2}\rho \left[\frac{1}{5}x^5 + \frac{1}{2}x^4 + x^3 + x^2 + x \right]_0^4 = \frac{1042}{5}\rho. \end{aligned}$$

Therefore the centroid is

$$(\bar{x}, \bar{y}) = \left(\frac{M_y}{M}, \frac{M_x}{M} \right) = \left(\frac{(280/3)\rho}{(100/3)\rho}, \frac{(1042/5)\rho}{(100/3)\rho} \right) = \left(\frac{280}{100}, \frac{1042 \cdot 3}{100 \cdot 5} \right) = \left(\frac{14}{5}, \frac{1563}{250} \right).$$

21. The lamina is

Let the mass density of the lamina be ρ . Then the mass of the lamina is

$$M = \rho \int_0^4 x^{1/2} dx = \rho \left[\frac{2}{3}x^{3/2} \right]_0^4 = \frac{16}{3}\rho$$

and the moments are

$$M_y = \rho \int_0^4 x \cdot x^{1/2} dx = \rho \int_0^4 x^{3/2} dx = \rho \left[\frac{2}{5}x^{5/2} \right]_0^4 = \frac{64}{5}\rho$$

$$M_x = \frac{1}{2}\rho \int_0^4 (x^{1/2})^2 dx = \frac{1}{2}\rho \int_0^4 x dx = \frac{1}{2}\rho \left[\frac{1}{2}x^2 \right]_0^4 = 4\rho.$$

Therefore the centroid is

$$(\bar{x}, \bar{y}) = \left(\frac{M_y}{M}, \frac{M_x}{M} \right) = \left(\frac{(64/5)\rho}{(16/3)\rho}, \frac{4\rho}{(16/3)\rho} \right) = \left(\frac{64 \cdot 3}{16 \cdot 5}, \frac{4 \cdot 3}{16} \right) = \boxed{\left(\frac{12}{5}, \frac{3}{4} \right)}.$$

22. The lamina is shown below:

Let the mass density of the lamina be ρ . Then the mass of the lamina is

$$M = \rho \int_0^8 x^{1/3} dx = \rho \left[\frac{3}{4} x^{4/3} \right]_0^8 = 12\rho$$

and the moments are

$$\begin{aligned} M_y &= \rho \int_0^8 x \cdot x^{1/3} dx = \rho \int_0^8 x^{4/3} dx = \rho \left[\frac{3}{7} x^{7/3} \right]_0^8 = \frac{384}{7} \rho \\ M_x &= \frac{1}{2} \rho \int_0^8 \left(x^{1/3} \right)^2 dx = \frac{1}{2} \rho \int_0^8 x^{2/3} dx = \frac{1}{2} \rho \left[\frac{3}{5} x^{5/3} \right]_0^8 = \frac{48}{5} \rho. \end{aligned}$$

Therefore the centroid is

$$(\bar{x}, \bar{y}) = \left(\frac{M_y}{M}, \frac{M_x}{M} \right) = \left(\frac{(384/7)\rho}{12\rho}, \frac{(48/5)\rho}{12\rho} \right) = \left(\frac{384}{7 \cdot 12}, \frac{48}{5 \cdot 12} \right) = \boxed{\left(\frac{32}{7}, \frac{4}{5} \right)}.$$

23. The circle and the surface are shown below:

The circle has a center of $(4, 0)$ and a radius of 3. It is symmetric about the point $(4, 0)$, so its centroid is $(\bar{x}, \bar{y}) = (4, 0)$. The distance from $(4, 0)$ to the axis of revolution (the y -axis) is 4, and the area of the circle is $\pi \cdot 3^2 = 9\pi$. The circle does not intersect the y -axis, so by Pappus' Theorem, the volume of the solid of revolution is

$$2\pi Ad = 2\pi \cdot 9\pi \cdot 4 = \boxed{72\pi^2}.$$

24. The circle and the surface are shown below:

The circle has a center of $(0, 2)$ and a radius of 1. It is symmetric about the point $(0, 2)$, so its centroid is $(\bar{x}, \bar{y}) = (0, 2)$. The distance from $(0, 2)$ to the axis of revolution (the x -axis) is 2, and the area of the circle is $\pi \cdot 1^2 = \pi$. The circle does not intersect the x -axis, so by Pappus's Theorem, the volume of the solid of revolution is

$$2\pi Ad = 2\pi \cdot \pi \cdot 2 = \boxed{4\pi^2}.$$

Applications and Extensions

25. If the mass density is ρ , then the mass is the mass of the circle of radius 1 plus the mass of the square of side 2, so it is $(4 + \pi)\rho$. By symmetry, since the figure is symmetric around the line $x = 1$, we have $\bar{x} = 1$. To compute $\bar{y}$, we will need the moment M_x . This figure is the union of a non-overlapping square and circle, so its moment is the sum of the individual moments. The center of the square, at $(1, 1)$, is its centroid, and its mass is 4ρ , so we have

$$1 = \frac{M_1}{4\rho}, \text{ so that } M_1 = 4\rho.$$

The center of the circle, at $(1, 3)$, is its centroid, and its mass is $\pi\rho$, so we have

$$3 = \frac{M_2}{\pi\rho}, \text{ so that } M_2 = 3\pi\rho.$$

So for the figure as a whole, we have $M_x = (4 + 3\pi)\rho$, and then

$$(\bar{x}, \bar{y}) = \left(1, \frac{(4 + 3\pi)\rho}{(4 + \pi)\rho}\right) = \boxed{\left(1, \frac{4 + 3\pi}{4 + \pi}\right)}.$$

26. This triangle has a base of 4 and a height of 4, so its area is $\frac{1}{2} \cdot 4 \cdot 4 = 8$ and then its mass is 8ρ . By symmetry, $\bar{x} = 0$. To compute $\bar{y}$, note that the triangle is the sum of two non-overlapping triangles, one for $x \leq 0$ and one for $x \geq 0$. For $x \leq 0$, the diagonal side of the triangle is the line $y = 4 + 2x$, while for $x \geq 0$, the diagonal side is the line $y = 4 - 2x$. So the moment M_x is the sum of these two moments, or

$$\begin{aligned} M_x &= \frac{1}{2}\rho \int_{-2}^0 (4 + 2x)^2 dx + \frac{1}{2}\rho \int_0^2 (4 - 2x)^2 dx \\ &= \frac{1}{2}\rho \left(\left[\frac{1}{6}(4 + 2x)^3 \right]_{-2}^0 + \left[-\frac{1}{6}(4 - 2x)^3 \right]_0^2 \right) \\ &= \frac{1}{2}\rho \left(\frac{32}{3} + \frac{32}{3} \right) = \frac{32}{3}\rho. \end{aligned}$$

Therefore the centroid is

$$(\bar{x}, \bar{y}) = \left(0, \frac{(32/3)\rho}{8\rho}\right) = \boxed{\left(0, \frac{4}{3}\right)}.$$

27. This triangle has a base of $2c$ and a height of b , so its area is bc and then its mass is bcp , where ρ is the mass density of the lamina. The triangle is composed of two nonoverlapping triangles, one of which has vertices $(-c, 0)$, $(a, 0)$ and (a, b) and the other of which has vertices $(a, 0)$, $(c, 0)$ and (a, b) . The moments of the given region about either axis are the sum of the moments of these two triangles about that axis. For the first triangle, the equation of the diagonal edge is

$$y - 0 = \frac{b - 0}{a - (-c)}(x - (-c)), \text{ or } y = \frac{b}{a + c}(x + c).$$

Therefore its moments are

$$\begin{aligned}
 M_y &= \rho \int_{-c}^a x \left(\frac{b}{a+c} (x+c) \right) dx \\
 &= \rho \cdot \frac{b}{a+c} \int_{-c}^a (x^2 + cx) dx \\
 &= \rho \cdot \frac{b}{a+c} \left[\frac{1}{3} x^3 + \frac{1}{2} cx^2 \right]_{-c}^a \\
 &= \rho \cdot \frac{b}{a+c} \left(\frac{1}{6} (2a^3 + 3a^2c - c^3) \right) \\
 &= \rho \cdot \frac{b}{a+c} \left(\frac{1}{6} (2a-c)(a+c)^2 \right) \\
 &= \frac{1}{6} b(2a-c)(a+c)\rho
 \end{aligned}$$

$$\begin{aligned}
 M_x &= \frac{1}{2} \rho \int_{-c}^a \left(\frac{b}{a+c} (x+c) \right)^2 dx \\
 &= \frac{1}{2} \rho \left(\frac{b}{a+c} \right)^2 \int_{-c}^a (x+c)^2 dx \\
 &= \frac{1}{2} \rho \left(\frac{b}{a+c} \right)^2 \left[\frac{1}{3} (x+c)^3 \right]_{-c}^a \\
 &= \frac{1}{2} \rho \frac{b^2}{(a+c)^2} \cdot \frac{1}{3} (a+c)^3 \\
 &= \frac{1}{6} b^2 (a+c) \rho.
 \end{aligned}$$

For the second triangle, the equation of the diagonal edge is

$$y - 0 = \frac{b-0}{a-c}(x-c), \text{ or } y = \frac{b}{a-c}(x-c).$$

Therefore its moments are

$$\begin{aligned}
 M_y &= \rho \int_a^c x \left(\frac{b}{a-c} (x-c) \right) dx \\
 &= \rho \cdot \frac{b}{a-c} \int_a^c (x^2 - cx) dx \\
 &= \rho \cdot \frac{b}{a-c} \left[\frac{1}{3} x^3 - \frac{1}{2} cx^2 \right]_a^c \\
 &= \rho \cdot \frac{b}{a-c} \left(-\frac{1}{6} (2a+c)(a-c)^2 \right) \\
 &= -\frac{1}{6} b(2a+c)(a-c)\rho
 \end{aligned}$$

$$\begin{aligned}
M_x &= \frac{1}{2}\rho \int_a^c \left(\frac{b}{a-c}(x-c) \right)^2 dx \\
&= \frac{1}{2}\rho \left(\frac{b}{a-c} \right)^2 \int_a^c (x-c)^2 dx \\
&= \frac{1}{2}\rho \left(\frac{b}{a-c} \right)^2 \left[\frac{1}{3}(x-c)^3 \right]_a^c \\
&= \frac{1}{2}\rho \frac{b^2}{(a-c)^2} \cdot \left(-\frac{1}{3}(a-c)^3 \right) \\
&= -\frac{1}{6}b^2(a-c)\rho.
\end{aligned}$$

So the moments for the figure as a whole are

$$\begin{aligned}
M_y &= \frac{1}{6}b(2a-c)(a+c)\rho - \frac{1}{6}b(2a+c)(a-c)\rho = \frac{1}{3}abc\rho \\
M_x &= \frac{1}{6}b^2(a+c)\rho - \frac{1}{6}b^2(a-c)\rho = \frac{1}{3}b^2c\rho.
\end{aligned}$$

Then the centroid is

$$(\bar{x}, \bar{y}) = \left(\frac{M_y}{M}, \frac{M_x}{M} \right) = \left(\frac{(abc/3)\rho}{bc\rho}, \frac{(b^2c/3)\rho}{bc\rho} \right) = \boxed{\left(\frac{a}{3}, \frac{b}{3} \right)}.$$

28. If the mass density is ρ , then the mass is the mass of the semicircle of radius 1 plus the mass of the 2×2 square, so it is $(4 + \frac{1}{2}\pi)\rho$. By symmetry, since the figure is symmetric around the line y -axis, we have $\bar{x} = 0$. To compute $\bar{y}$, we will need the moment M_x . This figure is the union of a non-overlapping square and circle, so its moment is the sum of the individual moments. The center of the square, at $(0, -1)$, is its centroid, and its mass is 4ρ , so we have

$$-1 = \frac{M_1}{4\rho}, \text{ so that } M_1 = -4\rho.$$

For the semicircle, we compute

$$M_2 = \frac{1}{2}\rho \int_{-1}^1 (\sqrt{1-x^2})^2 dx = \rho \int_{-1}^1 (1-x^2) dx = \frac{1}{2}\rho \left[x - \frac{1}{3}x^3 \right]_{-1}^1 = \frac{2}{3}\rho.$$

So for the entire lamina,

$$M_x = -4\rho + \frac{2}{3}\rho = -\frac{10}{3}\rho,$$

and the centroid is

$$(\bar{x}, \bar{y}) = \left(0, \frac{M_x}{M} \right) = \left(0, \frac{-(10/3)\rho}{(4 + (1/2)\pi)\rho} \right) = \boxed{\left(0, -\frac{20}{24 + 3\pi} \right)}.$$

29. The mass of the lamina is

$$M = \rho \int_0^a \frac{h}{a^2} x^2 dx = \rho \cdot \frac{h}{a^2} \int_0^a x^2 dx = \rho \cdot \frac{h}{a^2} \left[\frac{1}{3}x^3 \right]_0^a = \rho \cdot \frac{h}{a^2} \cdot \frac{1}{3}a^3 = \frac{1}{3}ah\rho.$$

The moments about the axes are

$$\begin{aligned}
M_y &= \rho \int_0^a x \left(\frac{h}{a^2} x^2 \right) dx = \rho \cdot \frac{h}{a^2} \int_0^a x^3 dx = \rho \cdot \frac{h}{a^2} \left[\frac{1}{4}x^4 \right]_0^a = \frac{1}{4}a^2 h\rho \\
M_x &= \frac{1}{2}\rho \int_0^a \left(\frac{h}{a^2} x^2 \right)^2 dx = \frac{1}{2}\rho \cdot \frac{h^2}{a^4} \int_0^a x^4 dx = \frac{1}{2}\rho \cdot \frac{h^2}{a^4} \left[\frac{1}{5}x^5 \right]_0^a = \frac{1}{10}ah^2.
\end{aligned}$$

Therefore the centroid is

$$(\bar{x}, \bar{y}) = \left(\frac{M_y}{M}, \frac{M_x}{M} \right) = \left(\frac{(a^2h/4)\rho}{(ah/3)\rho}, \frac{(ah^2/10)\rho}{(ah/3)\rho} \right) = \left(\frac{3a}{4}, \frac{3h}{10} \right).$$

30. By symmetry, $\bar{x} = 0$. Now, this figure is the union of two identical figures, one on each side of the y -axis; each of these figures has a moment about the x -axis that was determined in Problem 29 to be $\frac{1}{10}ah^2\rho$, so the total moment about the x -axis is $\frac{1}{5}ah^2\rho$. The mass of the lamina is twice the mass of the lamina in Problem 29, or $\frac{2}{3}ah\rho$. Therefore the centroid is

$$(\bar{x}, \bar{y}) = \left(0, \frac{M_x}{M} \right) = \left(0, \frac{(ah^2/5)\rho}{(2ah/3)\rho} \right) = \left(0, \frac{3h}{10} \right).$$

31. (a) The mass of the bat is

$$M = \int_0^L \lambda dx = \int_0^L kx dx = \left[\frac{1}{2}kx^2 \right]_0^L = \frac{1}{2}kL^2.$$

- (b) Solving the result of part (a) for k gives

$$k = \frac{2M}{L^2}.$$

- (c) The center of mass of the bat is

$$\bar{x} = \frac{\int_0^L x\lambda dx}{M} = \frac{2}{kL^2} \int_0^L kx^2 dx = \frac{2}{L^2} \left[\frac{1}{3}x^3 \right]_0^L = \frac{2}{3}L.$$

The center of mass is $\frac{2}{3}$ of the way from the handle to the end.

- (d) Answers will vary. The “sweet spot” is at the center of mass, since at that point the bat is neither underbalanced nor overbalanced, and you will be more likely to make solid contact.
- (e) Answers will vary. A small slice through the bat at any x gives a slice whose density is approximately $\lambda = kx$ and whose width is Δx , so the total mass is the limit of $\sum kx\Delta x$ as $\Delta x \rightarrow 0$; this is a Riemann sum whose limit is $\int_0^L kx dx = \int_0^L \lambda dx$.

32. The region is shown below:

The density is $\rho = 1$, so the mass (area) is

$$\int_1^2 \sqrt{x-1} dx = \left[\frac{2}{3}(x-1)^{3/2} \right]_1^2 = \frac{2}{3}.$$

Since we are revolving about the y -axis, we need to know the distance of the centroid from the y -axis to apply Pappus' Theorem; this distance is $\bar{x}$. So we compute M_y :

$$\begin{aligned} M_y &= \int_1^2 x\sqrt{x-1} \, dx \\ &= \int_1^2 ((x-1)\sqrt{x-1} + \sqrt{x-1}) \, dx \\ &= \int_1^2 ((x-1)^{3/2} dx + (x-1)^{1/2}) \, dx \\ &= \left[\frac{2}{5}(x-1)^{5/2} + \frac{2}{3}(x-1)^{3/2} \right]_1^2 = \frac{16}{15}. \end{aligned}$$

Then

$$\bar{x} = \frac{M_y}{M} = \frac{16/15}{2/3} = \frac{8}{5},$$

which is also the distance from the centroid to the axis of revolution. Therefore by Pappus's Theorem, the volume of the solid of revolution is

$$2\pi Ad = 2\pi \cdot \frac{2}{3} \cdot \frac{8}{5} = \boxed{\frac{32\pi}{15}}.$$

33. The region is shown below:

This triangle has base $5 - 3 = 2$ and height $3 - 2 = 1$, so its area is 1. We are revolving about the y -axis, so to apply Pappus' Theorem we will need to know the distance from the centroid of the region to the y -axis; this distance is $\bar{x}$, so we must compute M_y . This is

$$M_y = \int_3^5 x \left(\frac{9-x}{2} - 2 \right) dx = \int_3^5 \left(\frac{5}{2}x - \frac{1}{2}x^2 \right) dx = \left[\frac{5}{4}x^2 - \frac{1}{6}x^3 \right]_3^5 = \frac{11}{3}.$$

Therefore $\bar{x} = \frac{11}{3}$ (since $M = 1$), so that by Pappus' Theorem the volume of the solid of revolution is

$$2\pi Ad = 2\pi \cdot 1 \cdot \frac{11}{3} = \boxed{\frac{22}{3}\pi}.$$

34. This cone is the solid of revolution about the y -axis of a triangle whose vertices are $(0, 0)$, $(R, 0)$, and $(0, H)$. The equation of the diagonal edge of this triangle is $Hx + Ry = RH$, or $y = H - \frac{H}{R}x$. The area of the triangle is $\frac{1}{2}RH$. We will want the distance of the centroid from the y -axis, so we compute M_y :

$$M_y = \int_0^R x \left(H - \frac{H}{R}x \right) dx = \int_0^R \left(Hx - \frac{H}{R}x^2 \right) dx = \left[\frac{H}{2}x^2 - \frac{H}{3R}x^3 \right]_0^R = \frac{1}{6}HR^2.$$

Then

$$\bar{x} = \frac{(1/6)HR^2}{(1/2)RH} = \frac{1}{3}R,$$

so by Pappus' Theorem, the volume of the cone is

$$2\pi Ad = 2\pi A\bar{x} = 2\pi \cdot \frac{1}{2}RH \cdot \frac{1}{3}R = \boxed{\frac{1}{3}\pi R^2 H}.$$

35. The region is shown below:

We are revolving this about the x -axis, so using Pappus' Theorem, we will want the y -coordinate of the centroid, $\bar{y}$. We must split this up into two integrals, one from $x = 1$ to $x = 3$ and the other from $x = 3$ to $x = 5$. The equation of the diagonal line from $(1, 1)$ to $(3, 3)$ is $y = x$; the equation of the other diagonal line is $y = \frac{1}{2}(x + 1)$. Then computing M_x gives

$$\begin{aligned} M_x &= \frac{1}{2} \int_1^3 \left(x^2 - \left(\frac{1}{2}(x+1) \right)^2 \right) dx + \frac{1}{2} \int_3^5 \left(3^2 - \left(\frac{1}{2}(x+1) \right)^2 \right) dx \\ &= \frac{1}{2} \int_1^3 \left(\frac{3}{4}x^2 - \frac{1}{2}x - \frac{1}{4} \right) dx + \frac{1}{2} \int_3^5 \left(-\frac{1}{4}x^2 - \frac{1}{2}x + \frac{35}{4} \right) dx \\ &= \frac{1}{2} \left[\frac{1}{4}x^3 - \frac{1}{4}x^2 - \frac{1}{4}x \right]_1^3 + \frac{1}{2} \left[-\frac{1}{12}x^3 - \frac{1}{4}x^2 + \frac{35}{4}x \right]_3^5 \\ &= \frac{1}{2} \left(\frac{15}{4} - \left(-\frac{1}{4} \right) \right) + \frac{1}{2} \left(\frac{325}{12} - \frac{87}{4} \right) \\ &= \frac{14}{3}. \end{aligned}$$

Therefore $\bar{y} = \frac{M_x}{M} = \frac{7}{3}$, so by Pappus' Theorem, the volume of the solid is

$$2\pi Ad = 2\pi \cdot 2 \cdot \frac{7}{3} = \boxed{\frac{28}{3}\pi}.$$

36. The region is shown below:

The triangle has a base of 3 and a height of 4, so its area is $\frac{1}{2} \cdot 4 \cdot 3 = 6$. The equation of the diagonal edge of this triangle is $4x + 3y = 12$, or $y = 4 - \frac{4}{3}x$. Therefore the moments are

$$M_y = \int_0^3 x \left(4 - \frac{4}{3}x\right) dx = \int_0^3 \left(4x - \frac{4}{3}x^2\right) dx = \left[2x^2 - \frac{4}{9}x^3\right]_0^3 = 6$$

$$M_x = \frac{1}{2} \int_0^3 \left(4 - \frac{4}{3}x\right)^2 dx = \frac{1}{2} \left[-\frac{1}{4} \left(4 - \frac{4}{3}x\right)^3\right]_0^3 = -\frac{1}{8} \left[\left(4 - \frac{4}{3}x\right)^3\right]_0^3 = 8,$$

so that

$$(\bar{x}, \bar{y}) = \left(\frac{M_y}{M}, \frac{M_x}{M}\right) = \boxed{\left(1, \frac{4}{3}\right)}.$$

Challenge Problems

37. The triangle with two of the medians drawn is shown below:

Here A is the midpoint of the side opposite $(a, 0)$, B is the midpoint of the side opposite $(b, 0)$, and M is the point of intersection of those two medians. So we must show that M is the centroid of the triangle.

Since A is the midpoint of the segment from $(0, c)$ to $(b, 0)$, its coordinates are $\frac{1}{2}((0, c) + (b, 0)) = (\frac{b}{2}, \frac{c}{2})$. Similarly the coordinates of B are $(\frac{a}{2}, \frac{c}{2})$. So the equations of the two medians are

$$y - 0 = \frac{\frac{c}{2} - 0}{\frac{b}{2} - a}(x - a), \text{ or } y = \frac{c}{b - 2a}(x - a)$$

$$y - 0 = \frac{\frac{c}{2} - 0}{\frac{a}{2} - b}(x - b), \text{ or } y = \frac{c}{a - 2b}(x - b).$$

(Note that $b - 2a > 0$ since $b > 0$ and $a < 0$, so that the denominator in the first expression is nonzero. Similarly, $a - 2b < 0$. Therefore the denominators in these equations cannot be zero.) These two lines intersect when

$$\frac{c}{b - 2a}(x - a) = \frac{c}{a - 2b}(x - b).$$

Clearing fractions gives

$$\begin{aligned} c(a - 2b)(x - a) &= c(b - 2a)(x - b) \\ acx - a^2c - 2bcx + 2abc &= bcx - b^2c - 2acx + 2abc \\ (ac - 2bc)x - a^2c &= (bc - 2ac)x - b^2c \\ (ac - 2bc - bc + 2ac)x &= (b^2 - a^2)c \\ 3c(a - b)x &= (b - a)(b + a)c \\ -3x &= -(a + b) \\ x &= \frac{a + b}{3}. \end{aligned}$$

Again note that dividing through by $(a - b)c$ is justified since $a - b < 0$ and $c > 0$, so the product cannot be zero. Then

$$y = \frac{c}{b - 2a}(x - a) = \frac{c}{b - 2a} \cdot \left(\frac{a + b}{3} - a \right) = \frac{c}{b - 2a} \cdot \frac{b - 2a}{3} = \frac{c}{3}.$$

So the point M has coordinates $(\frac{1}{3}(a + b), \frac{1}{3}c)$. Now consider the third median, from $(0, c)$ to the x -axis. If $a = -b$, then the midpoint of the lower side of the triangle is the origin, and the median is the line $x = 0$ from $(0, c)$ to the origin. In this case, the point M has coordinates $(0, \frac{1}{3}c)$ since $a + b = 0$, and so the median from $(0, c)$ passes through M as well. If $a \neq -b$, then the midpoint of the lower side of the triangle is $\frac{a+b}{2}$, and the median has equation

$$y - c = \frac{0 - c}{\frac{a+b}{2} - 0}(x - 0), \text{ or } y = c - \frac{2c}{a + b}x.$$

Substituting the x -coordinate of M for x in this equation gives

$$y = c - \frac{2c}{a + b} \cdot \frac{a + b}{3} = c - \frac{2}{3}c = \frac{1}{3}c,$$

so that again the median passes through M . Therefore M is the point of intersection of all three medians.

It remains to show that M is the centroid of the triangle. The triangle has base $b - a$ and height c , so its area is $\frac{1}{2}c(b - a)$. This triangle is composed of two smaller triangles, one in the first quadrant and one in the second quadrant. The first quadrant triangle is bounded above by the line $y = -\frac{c}{b}x + c$ (note that $b \neq 0$), so its moments are

$$\begin{aligned} M_y &= \int_0^b x \left(-\frac{c}{b}x + c \right) dx = \int_0^b \left(cx - \frac{c}{b}x^2 \right) dx = \left[\frac{1}{2}cx^2 - \frac{c}{3b}x^3 \right]_0^b = \frac{1}{6}cb^2 \\ M_x &= \frac{1}{2} \int_0^b \left(-\frac{c}{b}x + c \right)^2 dx = \frac{1}{2} \left[-\frac{b}{3c} \left(-\frac{c}{b}x + c \right)^3 \right]_0^b = \frac{1}{6}bc^2. \end{aligned}$$

The second quadrant triangle is bounded above by the line $y = -\frac{c}{a}x + c$ (note that $a \neq 0$), so its moments are

$$M_y = \int_a^0 x \left(-\frac{c}{a}x + c \right) dx = \int_a^0 \left(cx - \frac{c}{a}x^2 \right) dx = \left[\frac{1}{2}cx^2 - \frac{c}{3a}x^3 \right]_a^0 = -\frac{1}{6}ca^2$$

$$M_x = \frac{1}{2} \int_a^0 \left(-\frac{c}{a}x + c \right)^2 dx = \frac{1}{2} \left[-\frac{a}{3c} \left(-\frac{c}{a}x + c \right)^3 \right]_a^0 = -\frac{1}{6}ac^2.$$

The moments of the entire figure are the sum of the moments of each figure, so the centroid of this triangle is

$$\begin{aligned} (\bar{x}, \bar{y}) &= \left(\frac{M_y}{M}, \frac{M_x}{M} \right) \\ &= \left(\frac{(1/6)cb^2 - (1/6)ca^2}{(1/2)c(b-a)}, \frac{(1/6)bc^2 - (1/6)ac^2}{(1/2)c(b-a)} \right) \\ &= \left(\frac{b^2 - a^2}{3(b-a)}, \frac{bc - ac}{3(b-a)} \right) \\ &= \left(\frac{1}{3}(a+b), \frac{1}{3}c \right). \end{aligned}$$

These are the coordinates of the point M computed above, so that the centroid of a triangle is the intersection of the medians.

38. Suppose the region is defined as shown in the diagram. As in the text, partition the interval $[a, b]$ into n subintervals

$$[a, x_1], [x_1, x_2], \dots, [x_{n-1}, b] \quad a = x_0, \quad b = x_n.$$

Each of these has width $\Delta x = \frac{b-a}{n}$. Let u_i be the midpoint of the i^{th} interval for $i = 1, 2, \dots, n$. That is,

$$u_i = \frac{x_{i-1} + x_i}{2}.$$

So we have partitioned the lamina into n nonoverlapping regions R_i for $i = 1, \dots, n$, each of which is roughly rectangular. The centroid of R_i is the point $\left(u_i, \frac{f(u_i) + g(u_i)}{2} \right)$, since that is the center of the rectangle. Further, the height of each rectangle is $f(u_i) - g(u_i)$, and the width is Δx , so the mass m_i of R_i is

$$m_i = \rho A_i = \rho(f(u_i) - g(u_i))\Delta x.$$

The moment of R_i about the y -axis is

$$M_y(R_i) = m_i u_i = \rho u_i (f(u_i) - g(u_i))\Delta x,$$

since the distance of the centroid from the y -axis is u_i . Adding up these moments over all rectangles gives

$$M_y \approx \rho \sum_{i=1}^n u_i (f(u_i) - g(u_i))\Delta x.$$

This is a Riemann sum whose limit as $n \rightarrow \infty$ is

$$M_y = \rho \int_a^b x(f(x) - g(x)) dx.$$

Similarly, the moment of R_i about the x -axis is the product of its mass and the distance of its centroid from the x -axis:

$$M_x(R_i) = m_i \cdot \frac{1}{2}(f(u_i) + g(u_i)) = \rho(f(u_i) - g(u_i))\Delta x \cdot \frac{1}{2}(f(u_i) + g(u_i)) = \frac{1}{2}\rho(f(u_i)^2 - g(u_i)^2)\Delta x.$$

Adding up these moments over all rectangles gives

$$M_x \approx \frac{1}{2} \rho \sum_{i=1}^n (f(u_i)^2 - g(u_i)^2) \Delta x.$$

This is a Riemann sum whose limit as $n \rightarrow \infty$ is

$$M_x = \frac{1}{2} \rho \int_a^b (f(x)^2 - g(x)^2) dx.$$

Finally, the mass of the lamina is ρ times the area between the curves, which is

$$M = \rho \int_a^b (f(x) - g(x)) dx.$$

Therefore the centroid of the lamina is

$$\begin{aligned} (\bar{x}, \bar{y}) &= \left(\frac{M_y}{M}, \frac{M_x}{M} \right) = \left(\frac{\rho \int_a^b x(f(x) - g(x)) dx}{\rho \int_a^b (f(x) - g(x)) dx}, \frac{\frac{1}{2} \rho \int_a^b (f(x)^2 - g(x)^2) dx}{\rho \int_a^b (f(x) - g(x)) dx} \right) \\ &= \left(\frac{\int_a^b x(f(x) - g(x)) dx}{\int_a^b (f(x) - g(x)) dx}, \frac{\frac{1}{2} \int_a^b (f(x)^2 - g(x)^2) dx}{\int_a^b (f(x) - g(x)) dx} \right). \end{aligned}$$

39. The region is shown below:

The mass of the lamina is

$$M = \rho \int_{-1}^1 (x^{2/3} - x^2) dx = \rho \left[\frac{3}{5} x^{5/3} - \frac{1}{3} x^3 \right]_{-1}^1 = \frac{8}{15} \rho.$$

By symmetry, $\bar{x} = 0$, so we need only compute M_x to be able to find $\bar{y}$. From Problem 38, M_x is

$$M_x = \frac{1}{2} \int_{-1}^1 \left((x^{2/3})^2 - (x^2)^2 \right) \rho dx = \frac{1}{2} \rho \int_{-1}^1 (x^{4/3} - x^4) dx = \frac{1}{2} \rho \left[\frac{3}{7} x^{7/3} - \frac{1}{5} x^5 \right]_{-1}^1 = \frac{8}{35} \rho.$$

Therefore the centroid is

$$(\bar{x}, \bar{y}) = \left(0, \frac{M_x}{M} \right) = \boxed{\left(0, \frac{3}{7} \right)}.$$

40. The region is shown below:

The mass of the lamina is

$$M = \int_1^4 \left(\frac{1}{x} - \frac{1}{4} \right) \rho \, dx = \rho \left[\ln x - \frac{1}{4}x \right]_1^4 = \left(\ln 4 - \frac{3}{4} \right) \rho.$$

From Problem 38, the moments about the two axes are

$$M_y = \int_1^4 x \left(\frac{1}{x} - \frac{1}{4} \right) \rho \, dx = \rho \int_1^4 \left(1 - \frac{1}{4}x \right) \, dx = \rho \left[x - \frac{1}{8}x^2 \right]_1^4 = \frac{9}{8}\rho$$

$$M_x = \frac{1}{2} \int_1^4 \left(\left(\frac{1}{x} \right)^2 - \left(\frac{1}{4} \right)^2 \right) \rho \, dx = \frac{1}{2}\rho \int_1^4 \left(\frac{1}{x^2} - \frac{1}{16} \right) \, dx = \frac{1}{2}\rho \left[-\frac{1}{x} - \frac{1}{16}x \right]_1^4 = \frac{9}{32}\rho.$$

Therefore the centroid is

$$(\bar{x}, \bar{y}) = \left(\frac{M_y}{M}, \frac{M_x}{M} \right) = \left(\frac{9}{8 \ln 4 - 6}, \frac{9}{32 \ln 4 - 24} \right).$$

41. The region is shown below:

By symmetry, the area of the region is twice the area of that portion of the region lying in the first quadrant. In the first quadrant, $y = |x|$ is the line $y = x$, so we get for the total mass

$$M = 2 \int_0^1 ((-x^2 + 2) - x) \, dx = 2 \int_0^1 (-x^2 - x + 2) \rho \, dx = 2\rho \left[-\frac{1}{3}x^3 - \frac{1}{2}x^2 + 2x \right]_0^1 = \frac{7}{3}\rho.$$

Again by symmetry, $\bar{x} = 0$, so we need only compute $\bar{y}$. Using symmetry yet again, the moment of the first quadrant region and the moment of the second quadrant region about the x -axis are equal,

so to compute M_x , we compute it for the first quadrant region and double it (using the hint preceding Problems 25–30). Therefore the moment of the entire region about the x -axis is

$$M_x = 2 \cdot \frac{1}{2} \int_0^1 ((-x^2 + 2)^2 - x^2) \rho \, dx = \rho \int_0^1 (x^4 - 5x^2 + 4) \, dx = \rho \left[\frac{1}{5}x^5 - \frac{5}{3}x^3 + 4x \right]_0^1 = \frac{38}{15}\rho.$$

Therefore the centroid is

$$(\bar{x}, \bar{y}) = \left(0, \frac{M_x}{M} \right) = \boxed{\left(0, \frac{38}{35} \right)}.$$

42. The region is shown below:

The mass of the region is

$$M = \int_0^1 (\sqrt{x} - x^2) \rho \, dx = \rho \left[\frac{2}{3}x^{3/2} - \frac{1}{3}x^3 \right]_0^1 = \frac{1}{3}\rho.$$

From Problem 38, the moments are

$$M_y = \int_0^1 x (\sqrt{x} - x^2) \rho \, dx = \int_0^1 (x^{3/2} - x^3) \rho \, dx = \rho \left[\frac{2}{5}x^{5/2} - \frac{1}{4}x^4 \right]_0^1 = \frac{3}{20}\rho$$

$$M_x = \frac{1}{2} \int_0^1 ((\sqrt{x})^2 - (x^2)^2) \rho \, dx = \frac{1}{2}\rho \int_0^1 (x - x^4) \, dx = \frac{1}{2}\rho \left[\frac{1}{2}x^2 - \frac{1}{5}x^5 \right]_0^1 = \frac{3}{20}\rho.$$

Therefore the centroid is

$$(\bar{x}, \bar{y}) = \left(\frac{M_y}{M}, \frac{M_x}{M} \right) = \boxed{\left(\frac{9}{20}, \frac{9}{20} \right)}.$$

43. The region is shown below:

The mass of the region is

$$M = \int_{-2}^1 ((4 - x^2) - (x + 2)) \rho \, dx = \rho \int_{-2}^1 (-x^2 - x + 2) \, dx = \rho \left[-\frac{1}{3}x^3 - \frac{1}{2}x^2 + 2x \right]_{-2}^1 = \frac{9}{2}\rho.$$

By Problem 38, the moments are

$$\begin{aligned} M_y &= \int_{-2}^1 x ((4 - x^2) - (x + 2)) \rho \, dx = \rho \int_{-2}^1 (-x^3 - x^2 + 2x) \, dx = \rho \left[-\frac{1}{4}x^4 - \frac{1}{3}x^3 + x^2 \right]_{-2}^1 = -\frac{9}{4}\rho \\ M_x &= \frac{1}{2} \int_{-2}^1 ((4 - x^2)^2 - (x + 2)^2) \rho \, dx = \frac{1}{2}\rho \int_{-2}^1 (x^4 - 9x^2 - 4x + 12) \, dx \\ &= \frac{1}{2}\rho \left[\frac{1}{5}x^5 - 3x^3 - 2x^2 + 12x \right]_{-2}^1 = \frac{54}{5}\rho. \end{aligned}$$

Therefore the centroid is

$$(\bar{x}, \bar{y}) = \left(\frac{M_y}{M}, \frac{M_x}{M} \right) = \left(-\frac{1}{2}, \frac{12}{5} \right).$$

44. The region is shown below:

The point of intersection in the first quadrant is the point where $9 - x^2 = x$, so that $x^2 + x - 9 = 0$. Using the quadratic formula, this gives

$$x = \frac{1}{2}(-1 + \sqrt{37}), \text{ so that the other intersection point is } x = \frac{1}{2}(1 - \sqrt{37}).$$

The mass of the region is twice the mass of the region in the first quadrant (where $|x| = x$), so it is

$$M = 2 \int_0^{\frac{1}{2}(-1+\sqrt{37})} (9 - x^2 - x) \rho \, dx = 2\rho \left[9x - \frac{1}{3}x^3 - \frac{1}{2}x^2 \right]_0^{\frac{1}{2}(-1+\sqrt{37})} = \frac{1}{6}(37\sqrt{37} - 55)\rho.$$

By symmetry, $\bar{x} = 0$, so we need only compute $\bar{y}$. Using symmetry yet again, the moment of the first quadrant region and the moment of the second quadrant region about the x -axis are equal, so to compute M_x , we compute it for the first quadrant region and double it (using the hint preceding Problems 25–30). Therefore the moment of the entire region about the x -axis is

$$\begin{aligned} M_x &= 2 \cdot \frac{1}{2} \int_0^{\frac{1}{2}(-1+\sqrt{37})} ((9 - x^2)^2 - x^2) \rho \, dx = \rho \int_0^{\frac{1}{2}(-1+\sqrt{37})} (x^4 - 19x^2 + 81) \, dx \\ &= \rho \left[\frac{1}{5}x^5 - \frac{19}{3}x^3 + 81x \right]_0^{\frac{1}{2}(-1+\sqrt{37})} = \frac{2}{15}(148\sqrt{37} + 23)\rho. \end{aligned}$$

Now,

$$\begin{aligned}\frac{M_x}{M} &= \frac{4(148\sqrt{37} + 23)}{5(37\sqrt{37} - 55)} = \frac{4(148\sqrt{37} + 23)(37\sqrt{37} + 55)}{5(37\sqrt{37} - 55)(37\sqrt{37} + 55)} \\ &= \frac{815508 + 35964\sqrt{37}}{238140} = \frac{1}{245}(37\sqrt{37} + 839).\end{aligned}$$

Therefore the centroid is

$$(\bar{x}, \bar{y}) = \left(0, \frac{1}{245}(37\sqrt{37} + 839) \right).$$

45. Suppose the region is defined as shown in Figures 69 and 70 in the text. As in the text, partition the interval $[a, b]$ into n subintervals

$$[a, x_1], [x_1, x_2], \dots, [x_{n-1}, b] \quad a = x_0, \quad b = x_n.$$

Each of these has width $\Delta x = \frac{b-a}{n}$. Let u_i be the midpoint of the i^{th} interval for $i = 1, 2, \dots, n$. That is,

$$u_i = \frac{x_{i-1} + x_i}{2}.$$

So we have partitioned the lamina into n nonoverlapping regions R_i for $i = 1, \dots, n$, each of which is roughly rectangular. Within R_i , the density of the lamina is roughly constant at $\rho(u_i)$, so the centroid of R_i is the point $(u_i, \frac{1}{2}f(u_i))$, since that is the center of R_i . Further, the height of each rectangle is $f(u_i)$, and the width is Δx , so the mass m_i of R_i is

$$m_i = \rho(u_i)A_i = \rho(u_i)f(u_i)\Delta x.$$

The mass of the lamina is therefore approximated by

$$M \approx \sum_{i=1}^n m_i = \sum_{i=1}^n \rho(u_i)f(u_i)\Delta x.$$

This is a Riemann sum whose limit as $n \rightarrow \infty$ is

$$M = \int_a^b \rho(x)f(x) dx.$$

The moment of R_i about the y -axis is

$$M_y(R_i) = m_i u_i = \rho(u_i)u_i f(u_i)\Delta x,$$

since the distance of the centroid from the y -axis is u_i . Adding up these moments over all rectangles gives

$$M_y \approx \sum_{i=1}^n \rho(u_i)u_i f(u_i)\Delta x.$$

This is a Riemann sum whose limit as $n \rightarrow \infty$ is

$$M_y = \int_a^b \rho(x)x f(x) dx.$$

Similarly, the moment of R_i about the x -axis is the product of its mass and the distance of its centroid from the x -axis:

$$M_x(R_i) = m_i \cdot \frac{1}{2}f(u_i) = \rho(u_i)f(u_i)\Delta x \cdot \frac{1}{2}f(u_i) = \frac{1}{2}\rho(u_i)f(u_i)^2\Delta x.$$

Adding up these moments over all rectangles gives

$$M_x \approx \frac{1}{2} \sum_{i=1}^n \rho(u_i) f(u_i)^2 \Delta x.$$

This is a Riemann sum whose limit as $n \rightarrow \infty$ is

$$M_x = \frac{1}{2} \int_a^b \rho(x) f(x)^2 dx.$$

Therefore the centroid of the lamina is

$$(\bar{x}, \bar{y}) = \left(\frac{M_y}{M}, \frac{M_x}{M} \right) = \left(\frac{\int_a^b \rho(x) x f(x) dx}{\int_a^b \rho(x) f(x) dx}, \frac{\frac{1}{2} \int_a^b \rho(x) f(x)^2 dx}{\int_a^b \rho(x) f(x) dx} \right).$$

46. The region is shown below:

From Problem 45, the mass of the lamina is

$$M = \int_a^b \rho(x) f(x) dx = \int_1^e \frac{1}{x^3} \cdot \frac{1}{2} x^2 dx = \frac{1}{2} \int_1^e \frac{1}{x} dx = \frac{1}{2} [\ln x]_1^e = \frac{1}{2}.$$

The moments about the two axes are

$$M_y = \int_a^b \rho(x) x f(x) dx = \int_1^e \frac{1}{x^3} \cdot x \cdot \frac{1}{2} x^2 dx = \frac{1}{2} \int_1^e 1 dx = \frac{1}{2} (e - 1)$$

$$M_x = \frac{1}{2} \int_a^b \rho(x) f(x)^2 dx = \frac{1}{2} \int_1^e \frac{1}{x^3} \cdot \frac{1}{4} x^4 dx = \frac{1}{8} \int_1^e x dx = \frac{1}{8} \left[\frac{1}{2} x^2 \right]_1^e = \frac{1}{16} (e^2 - 1).$$

Therefore the center of mass is

$$(\bar{x}, \bar{y}) = \left(\frac{M_y}{M}, \frac{M_x}{M} \right) = \left(e - 1, \frac{1}{8} (e^2 - 1) \right).$$

47. The region is shown below:

From Problems 38 and 45, the mass of the lamina is

$$\begin{aligned}
 M &= \int_0^8 \rho(x)(3 - \sqrt{x+1}) dx \\
 &= \int_0^8 (3x - x\sqrt{x+1}) dx \\
 &= \int_0^8 (3x - (x+1)\sqrt{x+1} + \sqrt{x+1}) dx \\
 &= \int_0^8 \left(3x - (x+1)^{3/2} + (x+1)^{1/2} \right) dx \\
 &= \left[\frac{3}{2}x^2 - \frac{2}{5}(x+1)^{5/2} + \frac{2}{3}(x+1)^{3/2} \right]_0^8 \\
 &= \frac{248}{15}.
 \end{aligned}$$

The moments about the two axes are

$$\begin{aligned}
 M_y &= \int_0^8 \rho(x)x(3 - \sqrt{x+1}) dx \\
 &= \int_0^8 (3x^2 - x^2\sqrt{x+1}) dx \\
 &= \int_0^8 (3x^2 - (x^2 + 2x + 1)\sqrt{x+1} + (2x+1)\sqrt{x+1}) dx \\
 &= \int_0^8 \left(3x^2 - (x+1)^{5/2} + 2(x+1)\sqrt{x+1} - \sqrt{x+1} \right) dx \\
 &= \int_0^8 \left(3x^2 - (x+1)^{5/2} + 2(x+1)^{3/2} - (x+1)^{1/2} \right) dx \\
 &= \left[x^3 - \frac{2}{7}(x+1)^{7/2} + \frac{4}{5}(x+1)^{5/2} - \frac{2}{3}(x+1)^{3/2} \right]_0^8 \\
 &= \frac{6688}{105}
 \end{aligned}$$

and

$$M_x = \frac{1}{2} \int_0^8 \rho(x) \left(3^2 - (\sqrt{x+1})^2 \right) dx = \int_0^8 x(8-x) dx = \int_0^8 (8x - x^2) dx = \left[4x^2 - \frac{1}{3}x^3 \right]_0^8 = \frac{128}{3}.$$

Therefore the center of mass is

$$(\bar{x}, \bar{y}) = \left(\frac{M_y}{M}, \frac{M_x}{M} \right) = \left(\frac{836}{217}, \frac{80}{31} \right).$$

48. From Problem 45, the mass of the lamina is

$$M = \int_0^3 \rho(x)f(x) dx = \int_0^3 x^2 dx = \left[\frac{1}{3}x^3 \right]_0^3 = 9.$$

The moments about the two axes are

$$\begin{aligned}
 M_y &= \int_0^3 \rho(x)xf(x) dx = \int_0^3 x^3 dx = \left[\frac{1}{4}x^4 \right]_0^3 = \frac{81}{4} \\
 M_x &= \frac{1}{2} \int_0^3 \rho(x)f(x)^2 dx = \int_0^3 x^3 dx = \frac{1}{2} \left[\frac{1}{4}x^4 \right]_0^3 = \frac{81}{8}.
 \end{aligned}$$

Therefore the center of mass is

$$(\bar{x}, \bar{y}) = \left(\frac{M_y}{M}, \frac{M_x}{M} \right) = \boxed{\left(\frac{9}{4}, \frac{9}{8} \right)}.$$

49. From Problem 45, the mass of the lamina is

$$M = \int_1^4 \rho(x)f(x) dx = \int_1^4 x(3x-1) dx = \int_1^4 (3x^2 - x) dx = \left[x^3 - \frac{1}{2}x^2 \right]_1^4 = \frac{111}{2}.$$

The moments about the two axes are

$$\begin{aligned} M_y &= \int_1^4 \rho(x)xf(x) dx = \int_1^4 x^2(3x-1) dx = \int_1^4 (3x^3 - x^2) dx = \left[\frac{3}{4}x^4 - \frac{1}{3}x^3 \right]_1^4 = \frac{681}{4} \\ M_x &= \frac{1}{2} \int_1^4 \rho(x)f(x)^2 dx = \int_1^4 x(3x-1)^2 dx = \frac{1}{2} \int_1^4 (9x^3 - 6x^2 + x) dx \\ &= \frac{1}{2} \left[\frac{9}{4}x^4 - 2x^3 + \frac{1}{2}x^2 \right]_1^4 = \frac{1821}{8}. \end{aligned}$$

Therefore the center of mass is

$$(\bar{x}, \bar{y}) = \left(\frac{M_y}{M}, \frac{M_x}{M} \right) = \boxed{\left(\frac{227}{74}, \frac{607}{148} \right)}.$$

50. From Problem 45, the mass of the lamina is

$$M = \int_0^1 \rho(x)f(x) dx = \int_0^1 (x+1) \cdot 2x dx = \int_0^1 (2x^2 + 2x) dx = \left[\frac{2}{3}x^3 + x^2 \right]_0^1 = \frac{5}{3}.$$

The moments about the two axes are

$$\begin{aligned} M_y &= \int_0^1 \rho(x)xf(x) dx = \int_0^1 (x+1) \cdot x \cdot 2x dx = \int_0^1 (2x^3 + 2x^2) dx = \left[\frac{1}{2}x^4 + \frac{2}{3}x^3 \right]_0^1 = \frac{7}{6} \\ M_x &= \frac{1}{2} \int_0^1 \rho(x)f(x)^2 dx = \frac{1}{2} \int_0^1 (x+1)(2x)^2 dx = \frac{1}{2} \int_0^1 (4x^3 + 4x^2) dx = \frac{1}{2} \left[x^4 + \frac{4}{3}x^3 \right]_0^1 = \frac{7}{6}. \end{aligned}$$

Therefore the center of mass is

$$(\bar{x}, \bar{y}) = \left(\frac{M_y}{M}, \frac{M_x}{M} \right) = \boxed{\left(\frac{7}{10}, \frac{7}{10} \right)}.$$

51. From Problem 45, the mass of the lamina is

$$M = \int_1^4 \rho(x)f(x) dx = \int_1^4 (x+1)x dx = \int_1^4 (x^2 + x) dx = \left[\frac{1}{3}x^3 + \frac{1}{2}x^2 \right]_1^4 = \frac{57}{2}.$$

The moments about the two axes are

$$\begin{aligned} M_y &= \int_1^4 \rho(x)xf(x) dx = \int_1^4 (x+1) \cdot x \cdot x dx = \int_1^4 (x^3 + x^2) dx = \left[\frac{1}{4}x^4 + \frac{1}{3}x^3 \right]_1^4 = \frac{339}{4} \\ M_x &= \frac{1}{2} \int_1^4 \rho(x)f(x)^2 dx = \frac{1}{2} \int_1^4 (x+1) \cdot x^2 dx = \frac{1}{2} \int_1^4 (x^3 + x^2) dx = \frac{1}{2} \left[\frac{1}{4}x^4 + \frac{1}{3}x^3 \right]_1^4 = \frac{339}{8}. \end{aligned}$$

Therefore the center of mass is

$$(\bar{x}, \bar{y}) = \left(\frac{M_y}{M}, \frac{M_x}{M} \right) = \boxed{\left(\frac{113}{38}, \frac{113}{76} \right)}.$$

Chapter Review

1. The region is shown below:

Partitioning along the x -axis, we have $e^x \leq 4$, so the area is

$$\int_0^{\ln 4} (4 - e^x) dx = [4x - e^x]_0^{\ln 4} = \boxed{4 \ln 4 - 3}.$$

2. The region is shown below:

Partitioning along the x -axis, we have $x^2 \leq 18 - x^2$, so the area is

$$\int_{-3}^3 (18 - x^2 - x^2) dx = \int_{-3}^3 (18 - 2x^2) dx = \left[18x - \frac{2}{3}x^3 \right]_{-3}^3 = \boxed{72}.$$

3. The region is shown below:

Since we are given x in terms of y , it is more convenient to partition along the y -axis. There, we have $2y^2 \leq 2$, so the area is

$$\int_{-1}^1 (2 - 2y^2) \, dy = \left[2y - \frac{2}{3}y^3 \right]_{-1}^1 = \boxed{\frac{8}{3}}.$$

4. The region is shown below:

The equation $x + y = 4$ is the same as $y = 4 - x$. The graphs of $\frac{1}{x}$ and $4 - x$ meet when $\frac{1}{x} = 4 - x$, so when $4x - x^2 = 1$. This gives the quadratic $x^2 - 4x + 1 = 0$, which has roots $2 \pm \sqrt{3}$. Partitioning along the x -axis, we have $\frac{1}{x} \leq 4 - x$, so the area is

$$\begin{aligned} \int_{2-\sqrt{3}}^{2+\sqrt{3}} \left(4 - x - \frac{1}{x} \right) dx &= \left[4x - \frac{1}{2}x^2 - \ln x \right]_{2-\sqrt{3}}^{2+\sqrt{3}} \\ &= \left(8 + 4\sqrt{3} - \left(\frac{7}{2} + 2\sqrt{3} \right) - \ln(2 + \sqrt{3}) \right) \\ &\quad - \left(8 - 4\sqrt{3} - \left(\frac{7}{2} - 2\sqrt{3} \right) - \ln(2 - \sqrt{3}) \right) \\ &= 4\sqrt{3} + \ln \frac{2 - \sqrt{3}}{2 + \sqrt{3}} = \boxed{4\sqrt{3} + \ln(7 - 4\sqrt{3})}. \end{aligned}$$

5. The region is shown below:

Partitioning along the x -axis, we have $4 - x^2 \geq 3x$, so the area is

$$\int_{-4}^1 (4 - x^2 - 3x) dx = \left[4x - \frac{1}{3}x^3 - \frac{3}{2}x^2 \right]_{-4}^1 = \boxed{\frac{125}{6}}.$$

6. The region is shown below:

We use the washer method along the x -axis. Each outer radius is $4x - x^2$ and each inner radius is x^2 , so the volume is

$$V = \pi \int_0^2 \left((4x - x^2)^2 - (x^2)^2 \right) dx = \pi \int_0^2 (16x^2 - 8x^3) dx = \pi \left[\frac{16}{3}x^3 - 2x^4 \right]_0^2 = \boxed{\frac{32}{3}\pi}.$$

7. The region is shown below:

We use the shell method along the x -axis. Each height is $-x^2 + 5x - 6$, and each radius is x , so the volume is

$$V = 2\pi \int_2^3 x(-x^2 + 5x - 6) dx = 2\pi \int_2^3 (-x^3 + 5x^2 - 6x) dx = 2\pi \left[-\frac{1}{4}x^4 + \frac{5}{3}x^3 - 3x^2 \right]_2^3 = \boxed{\frac{5}{6}\pi}.$$

8. The region is shown below:

Since we are given equations expressing x in terms of y , and we are revolving about the y -axis, it is easiest to use the disk method along the y -axis. Each radius is $4 - y^2$, so the volume is

$$V = \pi \int_{-2}^2 (4 - y^2)^2 dy = \pi \int_{-2}^2 (y^4 - 8y^2 + 16) dy = \pi \left[\frac{1}{5}y^5 - \frac{8}{3}y^3 + 16y \right]_{-2}^2 = \boxed{\frac{512}{15}\pi}.$$

9. The region is shown below:

We use the disk method along the x -axis. Each radius is $\frac{1}{x}$, so the volume is

$$V = \pi \int_1^2 \left(\frac{1}{x} \right)^2 dx = \pi \int_1^2 \frac{1}{x^2} dx = \pi \left[-\frac{1}{x} \right]_1^2 = \boxed{\frac{1}{2}\pi}.$$

10. The region is shown below:

We use the washer method in the x direction. Each outer radius is $0 - (-4) = 4$, and each inner radius is $x^2 - 4 - (-4) = x^2$. Therefore the volume is

$$V = \pi \int_{-2}^2 \left(4^2 - (x^2)^2 \right) dx = \pi \int_{-2}^2 (16 - x^4) dx = \pi \left[16x - \frac{1}{5}x^5 \right]_{-2}^2 = \boxed{\frac{256}{5}\pi}.$$

11. The region is shown below:

We use the disk method along the x -axis. Each radius is $4x - x^2$, so the volume is

$$V = \pi \int_0^4 (4x - x^2)^2 dx = \pi \int_0^4 (16x^2 - 8x^3 + x^4) dx = \pi \left[\frac{16}{3}x^3 - 2x^4 + \frac{1}{5}x^5 \right]_0^4 = \boxed{\frac{512}{15}\pi}.$$

12. The region is shown below:

We use the shell method in the x direction, so we must first solve for y , giving $y = \sqrt{8x}$ (note that from the diagram, we take the positive square root). Revolving about $x = 2$, each radius is $2 - x$, and each height is $\sqrt{8x}$, so that the volume is

$$\begin{aligned} V &= 2\pi \int_0^2 (2-x)\sqrt{8x} \, dx = 4\pi\sqrt{2} \int_0^2 (2x^{1/2} - x^{3/2}) \, dx \\ &= 4\pi\sqrt{2} \left[\frac{4}{3}x^{3/2} - \frac{2}{5}x^{5/2} \right]_0^2 = 4\pi\sqrt{2} \left(\frac{8}{3}\sqrt{2} - \frac{8}{5}\sqrt{2} \right) = \boxed{\frac{128}{15}\pi}. \end{aligned}$$

13. The region is shown below:

It is easiest to use the shell method along the x -axis. Each height is $\frac{x^3}{2}$, and each radius is x , so the volume is

$$V = 2\pi \int_0^2 x \cdot \frac{x^3}{2} \, dx = \pi \int_0^2 x^4 \, dx = \pi \left[\frac{1}{5}x^5 \right]_0^2 = \boxed{\frac{32}{5}\pi}.$$

14. The region is shown below:

Use the washer method along the x -axis. Each outer radius is e^x and each inner radius is 1, so the volume is

$$V = \pi \int_0^1 \left((e^x)^2 - 1^2 \right) dx = \pi \int_0^1 (e^{2x} - 1) dx = \pi \left[\frac{1}{2} e^{2x} - x \right]_0^1 = \boxed{\frac{1}{2} \pi (e^2 - 3)}.$$

15. The region is shown below:

To revolve about $x = 4$, we could use either shells along the x -axis or washers in the y direction. We choose to use shells. Solving $y^2 = x^3$ for y gives $y = x^{3/2}$ (we choose the positive square root since this is a first quadrant region). Then each height is $8 - x^{3/2}$, and each radius is $4 - x$. Therefore the volume is

$$\begin{aligned} V &= 2\pi \int_0^4 (4 - x) (8 - x^{3/2}) dx = 2\pi \int_0^4 (32 - 8x - 4x^{3/2} + x^{5/2}) dx \\ &= 2\pi \left[32x - 4x^2 - \frac{8}{5} x^{5/2} + \frac{2}{7} x^{7/2} \right]_0^4 = \boxed{\frac{3456}{35} \pi}. \end{aligned}$$

16. Since $y' = \frac{3}{2}x^{1/2}$, the arc length is

$$L = \int_2^5 \sqrt{(y')^2 + 1} dx = \int_2^5 \sqrt{\frac{9}{4}x + 1} dx = \frac{1}{2} \int_2^5 \sqrt{9x + 4} dx.$$

Now use the substitution $u = 9x + 4$, so that $du = 9 dx$; then $x = 2$ corresponds to $u = 22$ and $x = 5$ to $u = 49$, so that we get

$$L = \frac{1}{2} \int_2^5 \sqrt{9x+4} dx = \frac{1}{18} \int_{22}^{49} u^{1/2} du = \frac{1}{18} \left[\frac{2}{3} u^{3/2} \right]_{22}^{49} = \boxed{\frac{1}{27} (343 - 22\sqrt{22})}.$$

17. We have $y' = \frac{x^2}{2} - \frac{1}{2x^2}$, so that

$$(y')^2 + 1 = \left(\frac{x^2}{2} - \frac{1}{2x^2} \right)^2 + 1 = \frac{x^2}{4} - \frac{1}{2} + \frac{1}{4x^4} + 1 = \frac{x^2}{4} + \frac{1}{2} + \frac{1}{4x^4} = \left(\frac{x^2}{2} + \frac{1}{2x^2} \right)^2.$$

Then the arc length is

$$L = \int_2^6 \sqrt{(y')^2 + 1} dy = \int_2^6 \left(\frac{x^2}{2} + \frac{1}{2x^2} \right) dx = \left[\frac{x^3}{6} - \frac{1}{2x} \right]_2^6 = \boxed{\frac{209}{6}}.$$

18. Partition along the y -axis. Then $x = g(y) = \sqrt{2} y^{3/2}$, so that $g'(y) = \frac{3}{\sqrt{2}} y^{1/2}$. Then the arc length is

$$\begin{aligned} L &= \int_0^2 \sqrt{(g'(y))^2 + 1} dy \\ &= \int_0^2 \sqrt{\frac{9}{2}x + 1} dy \\ &= \frac{1}{\sqrt{2}} \int_0^2 \sqrt{9x + 2} dy \\ &= \frac{1}{\sqrt{2}} \left[\frac{2}{27} (9x + 2)^{3/2} \right]_0^2 \\ &= \frac{\sqrt{2}}{27} (20\sqrt{20} - 2\sqrt{2}) \\ &= \boxed{\frac{4}{27} (10\sqrt{10} - 1)}. \end{aligned}$$

19. The center of mass is

$$\bar{x} = \frac{\sum_{i=1}^4 m_i x_i}{\sum_{i=1}^4 m_i} = \frac{1 \cdot (-1) + 3 \cdot 2 + 8 \cdot 14 + 1 \cdot 0}{1 + 3 + 8 + 1} = \boxed{9}.$$

20. The moments are

$$\begin{aligned} M_y &= \sum_{i=1}^4 m_i x_i = 2 \cdot (-4) + 2 \cdot 2 + 3 \cdot 4 + 2 \cdot (-3) = 2 \\ M_x &= \sum_{i=1}^4 m_i y_i = 2 \cdot 4 + 2 \cdot 3 + 3 \cdot 4 + 2 \cdot (-5) = 16 \end{aligned}$$

and the mass is $M = 2 + 2 + 3 + 2 = 9$, so the center of mass is

$$(\bar{x}, \bar{y}) = \left(\frac{M_y}{M}, \frac{M_x}{M} \right) = \boxed{\left(\frac{2}{9}, \frac{16}{9} \right)}.$$

21. The region is shown below:

The lines $x - y + 1 = 0$ and $3x + y - 13 = 0$ intersect when

$$y = x + 1 = 13 - 3x, \text{ so that } 4x = 12, \text{ or } x = 3, \text{ which is the point } (3, 4).$$

The lines $x - y + 1 = 0$ and $x + 3y - 7 = 0$ intersect when

$$x = y - 1 = 7 - 3y, \text{ so that } 4y = 8, \text{ or } y = 2, \text{ which is the point } (1, 2).$$

The lines $3x + y - 13 = 0$ and $x + 3y - 7 = 0$ intersect when

$$y = 13 - 3x = \frac{7}{3} - \frac{1}{3}x, \text{ so that } \frac{8}{3}x = \frac{32}{3}, \text{ or } x = 4, \text{ which is the point } (4, 1).$$

We partition along the x -axis, so we end up with two integrals, one from $x = 1$ to $x = 3$ and one from $x = 3$ to $x = 4$. The first has lower bound $y = \frac{7}{3} - \frac{1}{3}x$ and upper bound $y = x + 1$; the second has the same lower bound but has upper bound $y = 13 - 3x$. So the area is

$$\begin{aligned} A &= \int_1^3 \left((x+1) - \left(\frac{7}{3} - \frac{1}{3}x \right) \right) dx + \int_3^4 \left((13-3x) - \left(\frac{7}{3} - \frac{1}{3}x \right) \right) dx \\ &= \int_1^3 \left(\frac{4}{3}x - \frac{4}{3} \right) dx + \int_3^4 \left(-\frac{8}{3}x + \frac{32}{3} \right) dx \\ &= \left[\frac{2}{3}x^2 - \frac{4}{3}x \right]_1^3 + \left[-\frac{4}{3}x^2 + \frac{32}{3}x \right]_3^4 \\ &= \frac{8}{3} + \frac{4}{3} = \boxed{4}. \end{aligned}$$

22. The region is shown below:

An equilateral triangle with side a has height $a \sin 60^\circ = \frac{\sqrt{3}}{2}a$, so its area is $\frac{1}{2} \cdot a \cdot \frac{\sqrt{3}}{2}a = \frac{\sqrt{3}}{4}a^2$. With the fixed diameter as shown, along the x -axis, centered at the origin, the side length of the equilateral triangle at a given value of x is $2\sqrt{16 - x^2}$, so the area of the triangle is

$$\frac{\sqrt{3}}{4} \cdot \left(2\sqrt{16 - x^2}\right)^2 = (16 - x^2)\sqrt{3}.$$

Therefore the volume of the solid is

$$V = \int_{-4}^4 (16 - x^2)\sqrt{3} dx = \sqrt{3} \left[16x - \frac{1}{3}x^3 \right]_{-4}^4 = \boxed{\frac{256}{3}\sqrt{3}}.$$

23. The region is shown below:

Using the shell method along the y -axis, we solve for x , giving $x = \sqrt{9 - \frac{9}{4}y^2}$. Then the volume is

$$V = 2\pi \int_0^2 y \sqrt{9 - \frac{9}{4}y^2} dy = \pi \int_0^2 y \sqrt{36 - 9y^2} dy.$$

Now use the substitution $u = 36 - 9y^2$, so that $du = -18y dy$. Then $y = 0$ corresponds to $u = 36$, and $y = 2$ to $u = 0$, and the integral becomes

$$V = \pi \int_0^2 y \sqrt{36 - 9y^2} dy = \pi \cdot \left(-\frac{1}{18}\right) \int_{36}^0 u^{1/2} du = -\frac{\pi}{18} \left[\frac{2}{3} u^{3/2} \right]_{36}^0 = \boxed{8\pi}.$$

24. The region is shown below:

Place the origin at the tip of the cone, with the positive x -axis pointing in the direction of the base, so that the base of the cone is an ellipse with semi axes 2 and 1 at $x = 5$. The cross section at each value of x is an ellipse, and since both axes increase linearly, one from 0 to 2 and the other from 0 to 1 as x increases from 0 to 5, it follows that for a given value of x , the cross section at x is an ellipse

with semi axes $2 \cdot \frac{x}{5} = \frac{2x}{5}$ and $\frac{x}{5}$. We must integrate over the area of these ellipses. Now by the hint, the area of each ellipse is

$$\pi \cdot \left(\frac{2x}{5}\right) \cdot \left(\frac{x}{5}\right) = \frac{2}{25}\pi x^2$$

so the volume is

$$V = \int_0^5 \left(\frac{2}{25}\pi x^2\right) dx = \frac{2}{25}\pi \left[\frac{1}{3}x^3\right]_0^5 = \boxed{\frac{10}{3}\pi}.$$

25. The base is shown below:

Solving $4x + 5y = 20$ for y gives $y = 4 - \frac{4}{5}x$, so for a given value of x , the area of the semicircular cross section is

$$\frac{1}{2}\pi \left(\frac{d}{2}\right)^2 = \frac{1}{2}\pi \left(\frac{4 - \frac{4}{5}x}{2}\right)^2 = \frac{1}{8}\pi \left(16 - \frac{32}{5}x + \frac{16}{25}x^2\right).$$

Therefore the volume of the solid is

$$V = \int_0^5 \frac{1}{8}\pi \left(16 - \frac{32}{5}x + \frac{16}{25}x^2\right) dx = \frac{1}{8}\pi \left[16x - \frac{16}{5}x^2 + \frac{16}{75}x^3\right]_0^5 = \boxed{\frac{10}{3}\pi}.$$

26. We have $y' = x^{1/2}$, which is continuous for $x > 0$. So using the Arc Length Formula, the arc length from 0 to k is

$$L = \int_0^k \sqrt{(y')^2 + 1} dx = \int_0^k \sqrt{x + 1} dx = \left[\frac{2}{3}(x + 1)^{3/2}\right]_0^k = \frac{2}{3}((k + 1)^{3/2} - 1).$$

We want this length to be $\frac{52}{3}$, so setting the two equal and multiplying through by 3 gives

$$2((k + 1)^{3/2} - 1) = 52, \text{ or } (k + 1)^{3/2} - 1 = 26.$$

Add 1 to both sides and simplify to get $k = 8$. Therefore the point P is $(8, \frac{2}{3} \cdot 8^{3/2}) = \boxed{\left(8, \frac{16}{3}\right)}.$

27. The anchor must be lifted 150 ft; since it weighs 800 lb, the work involved in lifting the anchor itself is $800 \cdot 150 = 120000$ ft-lbs. The remainder of the work expended is for the chain itself. The weight density of the chain is 20 lb/ft, and the portion of the chain x ft below the boat must be lifted x ft. Therefore the total work expended in lifting the chain is

$$\int_0^{150} 20x dx = [10x^2]_0^{150} = 225000 \text{ ft-lbs.}$$

So the work required to lift the anchor and chain is $120000 + 225000 = \boxed{345000 \text{ ft-lbs}}.$

28. The container must be lifted 1200 m; since its mass is 1000 kg, its weight is 9800 N. Then the work involved in lifting the container itself is $1200 \cdot 9800 = 1.176 \times 10^7$ J. The remainder of the work expended is for the cable itself. The density of the cable is 3 kg/m, and the portion of the cable x ft below the surface must be lifted x ft. Therefore the total work expended in lifting the cable is

$$9.8 \int_0^{1200} 3x \, dx = 9.8 \left[\frac{3}{2} x^2 \right]_0^{1200} = 1.0584 \times 10^7 \text{ J.}$$

So the work required to lift the container and the cable is $1.176 \times 10^7 + 1.0584 \times 10^7 = \boxed{2.2344 \times 10^7 \text{ J}}$.

29. To determine the radius of the cross section x m below the top of the bowl, consider the following diagram, which shows a vertical cross section through the center of the bowl:

At a height x m below the top, the radius of the cross section is $\sqrt{36 - x^2}$, so that the area of the cross section at that height is $(36 - x^2)\pi$. That cross section must be lifted x m, so the work performed is

$$9.8 \int_2^6 1000x(36 - x^2)\pi \, dx = 9800\pi \int_2^6 (36h - x^3) \, dx = 9800\pi \left[18x^2 - \frac{1}{4}x^4 \right]_2^6 = \boxed{2.5088 \times 10^6 \pi \text{ J}}.$$

30. To determine k , note that a displacement of 0.2 m requires 4 N, so that $-4 = k \cdot 0.2$, or $k = -20$. So the equation of the spring is $F = -20x$. Then stretching it to 1.4 m, or 0.8 m from its equilibrium point, takes

$$\int_0^{0.8} (-20x) \, dx = [-10x^2]_0^{0.8} = \boxed{-6.4 \text{ N}}.$$

31. Let the equilibrium length of the spring be s , and the spring constant be k . Then

$$\begin{aligned} \int_{1-s}^{1.4-s} (-kx) \, dx &= \frac{1}{2} \int_{1.2-s}^{1.8-s} (-kx) \, dx \\ \left[-\frac{1}{2}kx^2 \right]_{1-s}^{1.4-s} &= \frac{1}{2} \left[-\frac{1}{2}kx^2 \right]_{1.2-s}^{1.8-s} \\ [x^2]_{1-s}^{1.4-s} &= \frac{1}{2} [x^2]_{1.2-s}^{1.8-s} \\ 2((1.4-s)^2 - (1-s)^2) &= (1.8-s)^2 - (1.2-s)^2 \\ -1.6s + 1.92 &= -1.2s + 1.8 \\ 0.4s &= 0.12 \\ s &= 0.3. \end{aligned}$$

The equilibrium length of the spring is $\boxed{0.3 \text{ m}}$.

32. Place the trapezoid on a Cartesian grid:

Then the equations of the two diagonal lines are:

$$y - 0 = \frac{3 - 0}{0 - 1}(x - 1), \text{ or } y = -3x + 3, \text{ or } x = -\frac{1}{3}y + 1$$

$$y - 0 = \frac{3 - 0}{4 - 3}(x - 3), \text{ or } y = 3x - 9, \text{ or } x = \frac{1}{3}y + 3.$$

So at any height y , the height of the water above a slice at that point is $3 - y$, and the width of the slice is $(\frac{1}{3}y + 3) - (-\frac{1}{3}y + 1) = \frac{2}{3}y + 2$. For water, $\rho g = 62.5$, so the force on the end of the trough is

$$\int_0^3 \rho g(3 - y) \left(\frac{2}{3}y + 2 \right) dy = \rho g \int_0^3 \left(-\frac{2}{3}y^2 + 6 \right) dy = \rho g \left[-\frac{2}{9}y^3 + 6y \right]_0^3 = 12 \cdot 62.5 = \boxed{750 \text{ lbs}}.$$

33. Since the tank's radius is 5 m, it is half-full. Position the y -axis at the center of one end of the tank, with the positive y -axis pointing down. Then at a given y -coordinate (depth), the width of the cross section of that end is $2\sqrt{5^2 - y^2}$, and the cross section lies y m below the surface. So the total force is

$$\begin{aligned} \int_0^5 \rho g y \cdot 2\sqrt{5^2 - y^2} dy &= 2\rho g \left[-\frac{1}{3}(5^2 - y^2)^{3/2} \right]_0^5 = -\frac{2}{3}\rho g \left((5^2 - 5^2)^{3/2} - (5^2 - 0^2)^{3/2} \right) \\ &= -\frac{2}{3}\rho g \cdot (-125) = \frac{2}{3} \cdot 737 \cdot 9.8 \cdot 125 \approx \boxed{601883 \text{ N}}. \end{aligned}$$

34. Placing the origin at the center of the bottom of the dam, the face of the dam is

Note that for water, $\rho g = 62.5$. The two diagonal lines have equations

$$y - 0 = \frac{80 - 0}{-500 - (-350)}(x - (-350)) \quad \text{or} \quad y = -\frac{8}{15}(x + 350)$$

$$y - 0 = \frac{80 - 0}{500 - 350}(x - 350) \quad \text{or} \quad y = \frac{8}{15}(x - 350).$$

Solving for x gives

$$x = -\frac{15}{8}y - 350, \quad x = \frac{15}{8}y + 350.$$

Therefore the width of a cross section at height y is

$$\left(\frac{15}{8}y + 350\right) - \left(-\frac{15}{8}y - 350\right) = \frac{15}{4}y + 700.$$

(a) If the dam is full, then the cross section at y lies $80 - y$ ft below the surface, and the total force is

$$\begin{aligned} \int_0^{80} \rho g(80 - y) \left(\frac{15}{4}y + 700\right) dy &= \rho g \int_0^{80} \left(-\frac{15}{4}y^2 - 400y + 56000\right) dy \\ &= \rho g \left[-\frac{5}{4}y^3 - 200y^2 + 56000y\right]_0^{80} \\ &= 2.56 \times 10^6 \rho g = \boxed{1.6 \times 10^8 \text{ lbs}}. \end{aligned}$$

(b) If the water has a depth of 60 ft, then the cross section at y lies only $60 - y$ ft below the surface, and the integral goes from 0 to 60, so the total force is

$$\begin{aligned} \int_0^{60} \rho g(60 - y) \left(\frac{15}{4}y + 700\right) dy &= \rho g \int_0^{60} \left(-\frac{15}{4}y^2 - 475y + 42000\right) dy \\ &= \rho g \left[-\frac{5}{4}y^3 - \frac{475}{2}y^2 + 42000y\right]_0^{60} \\ &= 1.395 \times 10^6 \rho g = \boxed{\approx 8.719 \times 10^7 \text{ lbs}}. \end{aligned}$$

op

35. The region is shown below:

The mass of the region is

$$M = \rho \int_0^9 \sqrt{x} dx = \rho \left[\frac{2}{3}x^{3/2}\right]_0^9 = 18\rho,$$

and the moments about the axes are

$$\begin{aligned} M_y &= \rho \int_0^9 x\sqrt{x} dx = \rho \int_0^9 x^{3/2} dx = \rho \left[\frac{2}{5}x^{5/2}\right]_0^9 = \frac{486}{5}\rho \\ M_x &= \rho \cdot \frac{1}{2} \int_0^9 (\sqrt{x})^2 dx = \frac{1}{2}\rho \int_0^9 x dx = \frac{1}{2}\rho \left[\frac{1}{2}x^2\right]_0^9 = \frac{81}{4}\rho. \end{aligned}$$

Therefore the centroid is

$$(\bar{x}, \bar{y}) = \left(\frac{M_y}{M}, \frac{M_x}{M}\right) = \boxed{\left(\frac{27}{5}, \frac{9}{8}\right)}.$$

36. This torus is the solid of revolution of the circle of radius $\frac{5-2}{2} = \frac{3}{2}$ centered at $(\frac{5+2}{2} = \frac{7}{2}, 0)$ about the y -axis. By symmetry, the centroid of this circle is at $(\frac{7}{2}, 0)$, which is $\frac{7}{2}$ cm from the axis of revolution. So by Pappus' Theorem, the volume of the torus is

$$2\pi Ad = 2\pi \cdot \pi \left(\frac{3}{2}\right)^2 \cdot \frac{7}{2} = \boxed{\frac{63}{4}\pi^2 \text{ cm}^2}.$$

37. The region is shown below:

Since we are dealing with areas, we may assume that the region is a homogeneous lamina, and we must compute its centroid. The diagonal line has equation $y = 12 - 2x$, so we have

$$\begin{aligned} A &= \int_3^6 (12 - 2x) dx = [12x - x^2]_3^6 = 36 - 27 = 9 \\ \bar{x} &= \frac{1}{A} \int_3^6 x(12 - 2x) dx = \frac{1}{9} \int_3^6 (12x - 2x^2) dx = \frac{1}{9} \left[6x^2 - \frac{2}{3}x^3 \right]_3^6 = \frac{1}{9}(72 - 36) = 4 \\ \bar{y} &= \frac{1}{2A} \int_3^6 (12 - 2x)^2 dx = \frac{1}{18} \int_3^6 (144 - 48x + 4x^2) dx = \frac{1}{18} \left[144x - 24x^2 + \frac{4}{3}x^3 \right]_3^6 \\ &= \frac{1}{18}(288 - 252) = 2. \end{aligned}$$

Then the centroid is at $(4, 2)$. We are revolving about the y -axis, so the distance from the centroid to the line of revolution is 4. The area of the region is 9. So by Pappus' Theorem, the volume of the solid of revolution is

$$V = 2\pi Ad = 2\pi \cdot 9 \cdot 4 = \boxed{72\pi}.$$

38. The region is shown below:

The two graphs intersect when $3\sqrt{x} = -x^2 + 6x - 2$. Looking at the graph, the intersection points appear to be at $x = 1$ and $x = 4$; substituting those values into the equation above reveals that $3\sqrt{1} = -1^2 + 6 \cdot 1 - 2$ and $3\sqrt{4} = -4^2 + 6 \cdot 4 - 2$, so that those are in fact the correct x -coordinates, and the two points of intersection are $(1, 3)$ and $(4, 6)$.

- (a) To revolve about $y = 0$ (the x -axis), use the washer method. Each outer radius is $-x^2 + 6x - 2$ and each inner radius is $3\sqrt{x}$, so the volume is

$$\begin{aligned} V &= \pi \int_1^4 \left((-x^2 + 6x - 2)^2 - (3\sqrt{x})^2 \right) dx \\ &= \pi \int_1^4 (x^4 - 12x^3 + 40x^2 - 33x + 4) dx \\ &= \pi \left[\frac{1}{5}x^5 - 3x^4 + \frac{40}{3}x^3 - \frac{33}{2}x^2 + 4x \right]_1^4 \\ &= \boxed{\frac{441}{10}\pi}. \end{aligned}$$

- (b) To revolve about $x = 0$ (the y -axis), use the shell method. The radius of each shell is x , and the height of each shell is $-x^2 + 6x - 2 - 3\sqrt{x}$, so the volume is

$$\begin{aligned} V &= 2\pi \int_1^4 x (-x^2 + 6x - 2 - 3\sqrt{x}) dx \\ &= 2\pi \int_1^4 (-x^3 + 6x^2 - 2x - 3x^{3/2}) dx \\ &= 2\pi \left[-\frac{1}{4}x^4 + 2x^3 - x^2 - \frac{6}{5}x^{5/2} \right]_1^4 \\ &= \boxed{\frac{201}{10}\pi}. \end{aligned}$$

- (c) To revolve about $y = -2$, use the washer method. Outer radii are $-x^2 + 6x - 2 - (-2) = -x^2 + 6x$, and inner radii are $3\sqrt{x} - (-2) = 3\sqrt{x} + 2$. Therefore the volume is

$$\begin{aligned} V &= \pi \int_1^4 \left((-x^2 + 6x)^2 - (3\sqrt{x} + 2)^2 \right) dx \\ &= \pi \int_1^4 (x^4 - 12x^3 + 36x^2 - 9x - 12x^{1/2} - 4) dx \\ &= \pi \left[\frac{1}{5}x^5 - 3x^4 + 12x^3 - \frac{9}{2}x^2 - 8x^{3/2} - 4x \right]_1^4 \\ &= \boxed{\frac{601}{10}\pi}. \end{aligned}$$

- (d) To revolve about $y = 8$, use the washer method. Each outer radius is $8 - 3\sqrt{x}$ and each inner radius is $8 - (-x^2 + 6x - 2) = x^2 - 6x + 10$, so the volume is

$$\begin{aligned} V &= \pi \int_1^4 \left((8 - 3\sqrt{x})^2 - (x^2 - 6x + 10)^2 \right) dx \\ &= \pi \int_1^4 (-x^4 + 12x^3 - 56x^2 + 129x - 48x^{1/2} - 36) dx \\ &= \pi \left[-\frac{1}{5}x^5 + 3x^4 - \frac{56}{3}x^3 + \frac{129}{2}x^2 - 32x^{3/2} - 36x \right]_1^4 \\ &= \boxed{\frac{199}{10}\pi}. \end{aligned}$$

- (e) To revolve about $x = -3$, use the shell method along the x -axis. The height of each shell is $-x^2 + 6x - 2 - 3\sqrt{x}$ and its radius is $x - (-3) = x + 3$, so the volume is

$$\begin{aligned}
 V &= 2\pi \int_1^4 (x+3) (-x^2 + 6x - 2 - 3\sqrt{x}) \, dx \\
 &= 2\pi \int_1^4 (-x^3 + 3x^2 + 16x - 3x^{3/2} - 9x^{1/2} - 6) \, dx \\
 &= 2\pi \left[-\frac{1}{4}x^4 + x^3 + 8x^2 - \frac{6}{5}x^{5/2} - 6x^{3/2} - 6x \right]_1^4 \\
 &= \boxed{\frac{441}{10}\pi}.
 \end{aligned}$$

- (f) To revolve about $x = 5$, use the shell method along the x -axis. The height of each shell is $-x^2 + 6x - 2 - 3\sqrt{x}$ and its radius is $5 - x$, so the volume is

$$\begin{aligned}
 V &= 2\pi \int_1^4 (5-x) (-x^2 + 6x - 2 - 3\sqrt{x}) \, dx \\
 &= 2\pi \int_1^4 (x^3 - 11x^2 + 32x + 3x^{3/2} - 15x^{1/2} - 10) \, dx \\
 &= 2\pi \left[\frac{1}{4}x^4 - \frac{11}{3}x^3 + 16x^2 + \frac{6}{5}x^{5/2} - 10x^{3/2} - 10x \right]_1^4 \\
 &= \boxed{\frac{199}{10}\pi}.
 \end{aligned}$$

Techniques of Integration

7.1: Integration by Parts

Concepts and Vocabulary

1. True.
2. $uv - \int v \, du$

Skill Building

3. We use integration by parts with $u = x$ and $dv = e^{2x} \, dx$. Then $du = dx$ and $v = \frac{1}{2}e^{2x}$. We obtain

$$\begin{aligned}\int x e^{2x} \, dx &= x \left(\frac{1}{2} e^{2x} \right) - \int \frac{1}{2} e^{2x} \, dx \\ &= \frac{1}{2} x e^{2x} - \frac{1}{2} \int e^{2x} \, dx \\ &= \frac{1}{2} x e^{2x} - \frac{1}{2} \left(\frac{1}{2} e^{2x} \right) + C \\ &= \boxed{\frac{1}{2} x e^{2x} - \frac{1}{4} e^{2x} + C}.\end{aligned}$$

4. We use integration by parts with $u = x$ and $dv = e^{-3x} \, dx$. Then $du = dx$ and $v = -\frac{1}{3}e^{-3x}$. We obtain

$$\begin{aligned}\int x e^{-3x} \, dx &= x \left(-\frac{1}{3} e^{-3x} \right) - \int \left(-\frac{1}{3} e^{-3x} \right) \, dx \\ &= -\frac{1}{3} x e^{-3x} + \frac{1}{3} \int e^{-3x} \, dx \\ &= -\frac{1}{3} x e^{-3x} + \frac{1}{3} \left(-\frac{1}{3} e^{-3x} \right) + C \\ &= \boxed{-\frac{1}{3} x e^{-3x} - \frac{1}{9} e^{-3x} + C}.\end{aligned}$$

5. We use integration by parts with $u = x$ and $dv = \cos x \, dx$. Then $du = dx$ and $v = \sin x$. We obtain

$$\begin{aligned}\int x \cos x \, dx &= x \sin x - \int \sin x \, dx \\ &= x \sin x - (-\cos x) + C \\ &= \boxed{x \sin x + \cos x + C}.\end{aligned}$$

6. We use integration by parts with $u = x$ and $dv = \sin(3x) dx$. Then $du = dx$ and $v = \frac{1}{3}(-\cos(3x)) = -\frac{1}{3}\cos(3x)$. We obtain

$$\begin{aligned}\int x \sin(3x) dx &= x \left(-\frac{1}{3} \cos(3x) \right) - \int \left(-\frac{1}{3} \cos(3x) \right) dx \\ &= -\frac{1}{3}x \cos(3x) + \frac{1}{3} \int \cos(3x) dx \\ &= -\frac{1}{3}x \cos(3x) + \frac{1}{3} \left(\frac{1}{3} \sin 3x \right) + C \\ &= \boxed{-\frac{1}{3}x \cos(3x) + \frac{1}{9} \sin(3x) + C}.\end{aligned}$$

7. We use integration by parts with $u = \ln x$ and $dv = \sqrt{x} dx = x^{1/2} dx$. Then $du = \frac{1}{x} dx$ and $v = \frac{2}{3}x^{3/2}$. We obtain

$$\begin{aligned}\int \sqrt{x} \ln x dx &= (\ln x) \left(\frac{2}{3}x^{3/2} \right) - \int \left(\frac{2}{3}x^{3/2} \right) \left(\frac{1}{x} \right) dx \\ &= \frac{2}{3}x^{3/2} \ln x - \frac{2}{3} \int x^{1/2} dx \\ &= \frac{2}{3}x^{3/2} \ln x - \frac{2}{3} \left(\frac{2}{3}x^{3/2} \right) + C \\ &= \boxed{\frac{2}{3}x^{3/2} \ln x - \frac{4}{9}x^{3/2} + C}.\end{aligned}$$

8. We use integration by parts with $u = \ln x$ and $dv = x^{-2} dx$. Then $du = \frac{1}{x} dx$ and $v = -x^{-1}$. We obtain

$$\begin{aligned}\int x^{-2} \ln x dx &= (\ln x)(-x^{-1}) - \int (-x^{-1}) \left(\frac{1}{x} \right) dx \\ &= -\frac{\ln x}{x} + \int x^{-2} dx \\ &= \boxed{-\frac{\ln x}{x} - \frac{1}{x} + C}.\end{aligned}$$

9. We use integration by parts with $u = \cot^{-1} x$ and $dv = dx$. Then $du = \left(-\frac{1}{1+x^2} \right) dx$ and $v = x$. We obtain

$$\begin{aligned}\int \cot^{-1} x dx &= (\cot^{-1} x)(x) - \int \left(-\frac{1}{1+x^2} \right) (x) dx \\ &= x \cot^{-1} x + \int \frac{x}{1+x^2} dx.\end{aligned}$$

Let $u = 1 + x^2$, then $du = 2x dx$, so $x dx = \frac{du}{2}$. We now substitute and obtain

$$\begin{aligned}\int \cot^{-1} x dx &= x \cot^{-1} x + \int \frac{1}{u} \frac{du}{2} \\ &= x \cot^{-1} x + \frac{1}{2} \int \frac{1}{u} du \\ &= x \cot^{-1} x + \frac{1}{2} \ln |u| + C \\ &= x \cot^{-1} x + \frac{1}{2} \ln |1 + x^2| + C \\ &= \boxed{x \cot^{-1} x + \frac{1}{2} \ln(1 + x^2) + C}.\end{aligned}$$

10. We use integration by parts with $u = \sin^{-1} x$ and $dv = dx$. Then $du = \frac{1}{\sqrt{1-x^2}} dx$ and $v = x$. We obtain

$$\begin{aligned}\int \sin^{-1} x \, dx &= (\sin^{-1} x)(x) - \int \left(\frac{1}{\sqrt{1-x^2}} \right)(x) \, dx \\ &= x \sin^{-1} x - \int \frac{x}{\sqrt{1-x^2}} \, dx.\end{aligned}$$

Let $u = 1 - x^2$, then $du = (-2x) \, dx$, so $x \, dx = \left(-\frac{du}{2}\right)$. We now substitute and obtain

$$\begin{aligned}\int \sin^{-1} x \, dx &= x \sin^{-1} x - \int \frac{1}{\sqrt{u}} \left(-\frac{du}{2}\right) \\ &= x \sin^{-1} x + \frac{1}{2} \int u^{-1/2} \, du \\ &= x \sin^{-1} x + \frac{1}{2} (2u^{1/2}) + C \\ &= \boxed{x \sin^{-1} x + \sqrt{1-x^2} + C}.\end{aligned}$$

11. We use integration by parts with $u = (\ln x)^2$ and $dv = dx$. Then $du = \frac{2 \ln x}{x} dx$ and $v = x$. We obtain

$$\begin{aligned}\int (\ln x)^2 \, dx &= (\ln x)^2 x - \int x \left(\frac{2 \ln x}{x} \right) \, dx \\ &= x(\ln x)^2 - 2 \int \ln x \, dx\end{aligned}$$

We use integration by parts again with $u = \ln x$ and $dv = dx$. Then $du = \frac{1}{x} dx$ and $v = x$. We obtain

$$\begin{aligned}\int (\ln x)^2 \, dx &= x(\ln x)^2 - 2 \left[(\ln x)x - \int x \left(\frac{1}{x} \right) \, dx \right] \\ &= x(\ln x)^2 - 2 \left[(\ln x)x - \int 1 \, dx \right] \\ &= x(\ln x)^2 - 2 [(\ln x)x - x] + C \\ &= \boxed{x(\ln x)^2 - 2x \ln x + 2x + C}.\end{aligned}$$

12. We use integration by parts with $u = (\ln x)^2$ and $dv = x \, dx$. Then $du = \frac{2 \ln x}{x} dx$ and $v = \frac{1}{2} x^2$. We obtain

$$\begin{aligned}\int x(\ln x)^2 \, dx &= (\ln x)^2 \left(\frac{1}{2} x^2 \right) - \int \left(\frac{1}{2} x^2 \right) \left(\frac{2 \ln x}{x} \right) \, dx \\ &= \frac{1}{2} x^2 (\ln x)^2 - \int x \ln x \, dx\end{aligned}$$

We use integration by parts again with $u = \ln x$ and $dv = x \, dx$. Then $du = \frac{1}{x} dx$ and

$v = \frac{1}{2}x^2$. We obtain

$$\begin{aligned}
 \int x(\ln x)^2 dx &= \frac{1}{2}x^2(\ln x)^2 - \left[(\ln x)\left(\frac{1}{2}x^2\right) - \int \left(\frac{1}{2}x^2\right)\left(\frac{1}{x}\right) dx \right] \\
 &= \frac{1}{2}x^2(\ln x)^2 - \frac{1}{2}x^2(\ln x) + \frac{1}{2} \int x dx \\
 &= \frac{1}{2}x^2(\ln x)^2 - \frac{1}{2}x^2(\ln x) + \frac{1}{2}\left(\frac{1}{2}x^2\right) + C \\
 &= \boxed{\frac{1}{2}x^2(\ln x)^2 - \frac{1}{2}x^2(\ln x) + \frac{1}{4}x^2 + C}.
 \end{aligned}$$

13. We use integration by parts with $u = x^2$ and $dv = \sin x dx$. Then $du = 2x dx$ and $v = -\cos x$. We obtain

$$\begin{aligned}
 \int x^2 \sin x dx &= x^2(-\cos x) - \int (-\cos x)(2x) dx \\
 &= -x^2 \cos x + 2 \int x \cos x dx
 \end{aligned}$$

We use integration by parts again with $u = x$ and $dv = \cos x dx$. Then $du = dx$ and $v = \sin x$. We obtain

$$\begin{aligned}
 \int x^2 \sin x dx &= -x^2 \cos x + 2 \left[x \sin x - \int \sin x dx \right] \\
 &= -x^2 \cos x + 2x \sin x - 2 \int \sin x dx \\
 &= -x^2 \cos x + 2x \sin x - 2(-\cos x) + C \\
 &= \boxed{-x^2 \cos x + 2x \sin x + 2 \cos x + C}.
 \end{aligned}$$

14. We use integration by parts with $u = x^2$ and $dv = \cos x dx$. Then $du = 2x dx$ and $v = \sin x$. We obtain

$$\begin{aligned}
 \int x^2 \cos x dx &= x^2(\sin x) - \int (\sin x)(2x) dx \\
 &= x^2 \sin x - 2 \int x \sin x dx
 \end{aligned}$$

We use integration by parts again with $u = x$ and $dv = \sin x dx$. Then $du = dx$ and $v = -\cos x$. We obtain

$$\begin{aligned}
 \int x^2 \cos x dx &= x^2 \sin x - 2 \left[x(-\cos x) - \int (-\cos x) dx \right] \\
 &= x^2 \sin x + 2x \cos x - 2 \int \cos x dx \\
 &= \boxed{x^2 \sin x + 2x \cos x - 2 \sin x + C}.
 \end{aligned}$$

15. We use integration by parts with $u = x \cos x$ and $dv = \cos x \, dx$. Then $du = (-x \sin x + \cos x) \, dx$ and $v = \sin x$. We obtain

$$\begin{aligned}
 \int x \cos^2 x \, dx &= (x \cos x)(\sin x) - \int (\sin x)(-x \sin x + \cos x) \, dx \\
 &= x \cos x \sin x + \int x \sin^2 x \, dx - \int \cos x \sin x \, dx \\
 &= x \cos x \sin x + \int x(1 - \cos^2 x) \, dx - \int \cos x \sin x \, dx \\
 &= x \cos x \sin x + \int x \, dx - \int x \cos^2 x \, dx - \int \cos x \sin x \, dx.
 \end{aligned}$$

We add $\int x \cos^2 x \, dx$ to each side, and then let $u = \sin x$, so $du = \cos x \, dx$ in the remaining integral. Upon substitution, we obtain

$$\begin{aligned}
 2 \int x \cos^2 x \, dx &= x \cos x \sin x + \frac{1}{2}x^2 - \int u \, du \\
 &= x \cos x \sin x + \frac{1}{2}x^2 - \frac{1}{2}u^2 + C \\
 &= x \cos x \sin x + \frac{1}{2}x^2 - \frac{1}{2}\sin^2 x + C.
 \end{aligned}$$

Finally, we divide by 2 to obtain

$$\int x \cos^2 x \, dx = \boxed{\frac{1}{2}x \cos x \sin x + \frac{1}{4}x^2 - \frac{1}{4}\sin^2 x + C}.$$

16. We use integration by parts with $u = x \sin x$ and $dv = \sin x \, dx$. Then $du = (x \cos x + \sin x) \, dx$ and $v = -\cos x$. We obtain

$$\begin{aligned}
 \int x \sin^2 x \, dx &= (x \sin x)(-\cos x) - \int (-\cos x)(x \cos x + \sin x) \, dx \\
 &= -x \cos x \sin x + \int x \cos^2 x \, dx + \int \cos x \sin x \, dx \\
 &= -x \cos x \sin x + \int x(1 - \sin^2 x) \, dx + \int \cos x \sin x \, dx \\
 &= -x \cos x \sin x + \int x \, dx - \int x \sin^2 x \, dx + \int \cos x \sin x \, dx.
 \end{aligned}$$

We add $\int x \sin^2 x \, dx$ to each side, and then let $u = \sin x$, so $du = \cos x \, dx$ in the remaining integral. Upon substitution, we obtain

$$\begin{aligned}
 2 \int x \sin^2 x \, dx &= -x \cos x \sin x + \frac{1}{2}x^2 + \int u \, du \\
 &= -x \cos x \sin x + \frac{1}{2}x^2 + \frac{1}{2}u^2 \\
 &= -x \cos x \sin x + \frac{1}{2}x^2 + \frac{1}{2}\sin^2 x.
 \end{aligned}$$

Finally, we divide by 2, add the constant of integration, and obtain

$$\int x \sin^2 x \, dx = \boxed{-\frac{1}{2}x \cos x \sin x + \frac{1}{4}x^2 + \frac{1}{4}\sin^2 x + C}.$$

17. We use integration by parts with $u = x$ and $dv = \sinh x \, dx$. Then $du = dx$ and $v = \cosh x$. We obtain

$$\begin{aligned}\int x \sinh x \, dx &= x \cosh x - \int \cosh x \, dx \\ &= \boxed{x \cosh x - \sinh x + C}.\end{aligned}$$

18. We use integration by parts with $u = x$ and $dv = \cosh x \, dx$. Then $du = dx$ and $v = \sinh x$. We obtain

$$\begin{aligned}\int x \cosh x \, dx &= x \sinh x - \int \sinh x \, dx \\ &= \boxed{x \sinh x - \cosh x + C}.\end{aligned}$$

19. We use integration by parts with $u = \cosh^{-1} x$ and $dv = dx$. Then $du = \frac{1}{\sqrt{x^2-1}} \, dx$ and $v = x$. We obtain

$$\int \cosh^{-1} x \, dx = (\cosh^{-1} x)x - \int x \left(\frac{1}{\sqrt{x^2-1}} \right) dx.$$

Let $u = x^2 - 1$, then $du = 2x \, dx$, so $x \, dx = \frac{du}{2}$. We substitute and obtain

$$\begin{aligned}\int \cosh^{-1} x \, dx &= x \cosh^{-1} x - \int u^{-1/2} \frac{du}{2} \\ &= x \cosh^{-1} x - \frac{1}{2} \int u^{-1/2} \, du \\ &= x \cosh^{-1} x - \frac{1}{2} (2\sqrt{u}) + C \\ &= \boxed{x \cosh^{-1} x - \sqrt{x^2-1} + C}.\end{aligned}$$

20. We use integration by parts with $u = \sinh^{-1} x$ and $dv = dx$. Then $du = \frac{1}{\sqrt{x^2+1}} \, dx$ and $v = x$. We obtain

$$\int \sinh^{-1} x \, dx = (\sinh^{-1} x)x - \int x \left(\frac{1}{\sqrt{x^2+1}} \right) dx.$$

Let $u = x^2 + 1$, then $du = 2x \, dx$, so $x \, dx = \frac{du}{2}$. We substitute and obtain

$$\begin{aligned}\int \sinh^{-1} x \, dx &= x \sinh^{-1} x - \int u^{-1/2} \frac{du}{2} \\ &= x \sinh^{-1} x - \frac{1}{2} \int u^{-1/2} \, du \\ &= x \sinh^{-1} x - \frac{1}{2} (2\sqrt{u}) + C \\ &= \boxed{x \sinh^{-1} x - \sqrt{x^2+1} + C}.\end{aligned}$$

21. We use integration by parts with $u = \sin(\ln x)$ and $dv = dx$. Then $du = \frac{\cos(\ln x)}{x} dx$ and $v = x$. We obtain

$$\begin{aligned}\int \sin(\ln x) dx &= (\sin(\ln x))x - \int x \left(\frac{\cos(\ln x)}{x} \right) dx \\ &= x \sin(\ln x) - \int \cos(\ln x) dx.\end{aligned}$$

We use integration by parts again with $u = \cos(\ln x)$ and $dv = dx$. Then $du = \frac{-\sin(\ln x)}{x} dx$ and $v = x$. We obtain

$$\begin{aligned}\int \sin(\ln x) dx &= x \sin(\ln x) - \left[(\cos(\ln x))x - \int x \left(\frac{-\sin(\ln x)}{x} \right) dx \right] \\ &= x \sin(\ln x) - x \cos(\ln x) - \int \sin(\ln x) dx.\end{aligned}$$

We add $\int \sin(\ln x) dx$ to each side, divide by 2, and add the constant of integration to obtain

$$\begin{aligned}2 \int \sin(\ln x) dx &= x \sin(\ln x) - x \cos(\ln x) + C \\ \int \sin(\ln x) dx &= \frac{1}{2}x \sin(\ln x) - \frac{1}{2}x \cos(\ln x) + C = \boxed{\frac{x}{2} [\sin(\ln x) - \cos(\ln x)] + C}.\end{aligned}$$

22. We use integration by parts with $u = \cos(\ln x)$ and $dv = dx$. Then $du = \frac{-\sin(\ln x)}{x} dx$ and $v = x$. We obtain

$$\begin{aligned}\int \cos(\ln x) dx &= (\cos(\ln x))x - \int x \left(\frac{-\sin(\ln x)}{x} \right) dx \\ &= x \cos(\ln x) + \int \sin(\ln x) dx.\end{aligned}$$

We use integration by parts again with $u = \sin(\ln x)$ and $dv = dx$. Then $du = \frac{\cos(\ln x)}{x} dx$ and $v = x$. We obtain

$$\begin{aligned}\int \cos(\ln x) dx &= x \cos(\ln x) + \left[(\sin(\ln x))x - \int x \left(\frac{\cos(\ln x)}{x} \right) dx \right] \\ &= x \cos(\ln x) + x \sin(\ln x) - \int \cos(\ln x) dx.\end{aligned}$$

We add $\int \cos(\ln x) dx$ to each side, divide by 2, and add the constant of integration to obtain

$$\begin{aligned}2 \int \cos(\ln x) dx &= x \cos(\ln x) + x \sin(\ln x) + C \\ \int \cos(\ln x) dx &= \boxed{\frac{1}{2}x \cos(\ln x) + \frac{1}{2}x \sin(\ln x) + C}.\end{aligned}$$

23. We use integration by parts with $u = (\ln x)^3$ and $dv = dx$. Then $du = 3\frac{(\ln x)^2}{x} dx$ and $v = x$. We obtain

$$\begin{aligned}\int (\ln x)^3 dx &= (\ln x)^3 x - \int x \left(\frac{3(\ln x)^2}{x} \right) dx \\ &= x(\ln x)^3 - 3 \int (\ln x)^2 dx.\end{aligned}$$

We use integration by parts again with $u = (\ln x)^2$ and $dv = dx$. Then $du = 2\frac{\ln x}{x} dx$ and $v = x$. We obtain

$$\begin{aligned}\int (\ln x)^3 dx &= x(\ln x)^3 - 3 \left[(\ln x)^2(x) - \int x \left(2\frac{\ln x}{x} \right) dx \right] \\ &= x(\ln x)^3 - 3x(\ln x)^2 + 6 \int \ln x dx.\end{aligned}$$

We use integration by parts again with $u = \ln x$ and $dv = dx$. Then $du = \frac{1}{x} dx$ and $v = x$. We obtain

$$\begin{aligned}\int (\ln x)^3 dx &= x(\ln x)^3 - 3x(\ln x)^2 + 6 \left[(\ln x)x - \int x \left(\frac{1}{x} \right) dx \right] \\ &= x(\ln x)^3 - 3x(\ln x)^2 + 6x \ln x - 6 \int dx \\ &= \boxed{x(\ln x)^3 - 3x(\ln x)^2 + 6x \ln x - 6x + C}.\end{aligned}$$

24. We use integration by parts with $u = (\ln x)^4$ and $dv = dx$. Then $du = 4\frac{(\ln x)^3}{x} dx$ and $v = x$. We obtain

$$\begin{aligned}\int (\ln x)^4 dx &= (\ln x)^4 x - \int x \left(\frac{4(\ln x)^3}{x} \right) dx \\ &= x(\ln x)^4 - 4 \int (\ln x)^3 dx.\end{aligned}$$

We use integration by parts again with $u = (\ln x)^3$ and $dv = dx$. Then $du = 3\frac{(\ln x)^2}{x} dx$ and $v = x$. We obtain

$$\begin{aligned}\int (\ln x)^4 dx &= x(\ln x)^4 - 4 \left[(\ln x)^3 x - \int x \left(\frac{3(\ln x)^2}{x} \right) dx \right] \\ &= x(\ln x)^4 - 4x(\ln x)^3 + 12 \int (\ln x)^2 dx.\end{aligned}$$

We use integration by parts again with $u = (\ln x)^2$ and $dv = dx$. Then $du = 2\frac{\ln x}{x} dx$ and $v = x$. We obtain

$$\begin{aligned}\int (\ln x)^4 dx &= x(\ln x)^4 - 4x(\ln x)^3 + 12 \left[(\ln x)^2(x) - \int x \left(2\frac{\ln x}{x} \right) dx \right] \\ &= x(\ln x)^4 - 4x(\ln x)^3 + 12x(\ln x)^2 - 24 \int \ln x dx.\end{aligned}$$

We use integration by parts again with $u = \ln x$ and $dv = dx$. Then $du = \frac{1}{x} dx$ and $v = x$. We obtain

$$\begin{aligned}\int (\ln x)^4 dx &= x(\ln x)^4 - 4x(\ln x)^3 + 12x(\ln x)^2 - 24 \left[(\ln x)x - \int x \left(\frac{1}{x} \right) dx \right] \\ &= x(\ln x)^4 - 4x(\ln x)^3 + 12x(\ln x)^2 - 24x \ln x + 24 \int dx \\ &= \boxed{x(\ln x)^4 - 4x(\ln x)^3 + 12x(\ln x)^2 - 24x \ln x + 24x + C}.\end{aligned}$$

25. We use integration by parts with $u = (\ln x)^2$ and $dv = x^2 dx$. Then $du = 2\frac{\ln x}{x} dx$ and $v = \frac{1}{3}x^3$. We obtain

$$\begin{aligned}\int x^2(\ln x)^2 dx &= (\ln x)^2 \left(\frac{1}{3}x^3 \right) - \int \left(\frac{1}{3}x^3 \right) \left(2\frac{\ln x}{x} \right) dx \\ &= \frac{1}{3}x^3(\ln x)^2 - \frac{2}{3} \int x^2 \ln x dx.\end{aligned}$$

We use integration by parts again with $u = \ln x$ and $dv = x^2 dx$. Then $du = \frac{dx}{x}$ and $v = \frac{1}{3}x^3$. We obtain

$$\begin{aligned}\int x^2(\ln x)^2 dx &= \frac{1}{3}x^3(\ln x)^2 - \frac{2}{3} \left[(\ln x) \left(\frac{1}{3}x^3 \right) - \int \left(\frac{1}{3}x^3 \right) \frac{dx}{x} \right] \\ &= \frac{1}{3}x^3(\ln x)^2 - \frac{2}{9}x^3 \ln x + \frac{2}{9} \int x^2 dx \\ &= \frac{1}{3}x^3(\ln x)^2 - \frac{2}{9}x^3 \ln x + \frac{2}{9} \left(\frac{1}{3}x^3 \right) + C \\ &= \boxed{\frac{1}{3}x^3(\ln x)^2 - \frac{2}{9}x^3 \ln x + \frac{2}{27}x^3 + C}.\end{aligned}$$

26. We use integration by parts with $u = (\ln x)^2$ and $dv = x^3 dx$. Then $du = 2\frac{\ln x}{x} dx$ and $v = \frac{1}{4}x^4$. We obtain

$$\begin{aligned}\int x^3(\ln x)^2 dx &= (\ln x)^2 \left(\frac{1}{4}x^4 \right) - \int \left(\frac{1}{4}x^4 \right) \left(2\frac{\ln x}{x} \right) dx \\ &= \frac{1}{4}x^4(\ln x)^2 - \frac{1}{2} \int x^3 \ln x dx.\end{aligned}$$

We use integration by parts again with $u = \ln x$ and $dv = x^3 dx$. Then $du = \frac{dx}{x}$ and $v = \frac{1}{4}x^4$. We obtain

$$\begin{aligned}\int x^3(\ln x)^2 dx &= \frac{1}{4}x^4(\ln x)^2 - \frac{1}{2} \left[(\ln x) \left(\frac{1}{4}x^4 \right) - \int \left(\frac{1}{4}x^4 \right) \frac{dx}{x} \right] \\ &= \frac{1}{4}x^4(\ln x)^2 - \frac{1}{8}x^4 \ln x + \frac{1}{8} \int x^3 dx \\ &= \frac{1}{4}x^4(\ln x)^2 - \frac{1}{8}x^4 \ln x + \frac{1}{8} \left(\frac{1}{4}x^4 \right) + C \\ &= \boxed{\frac{1}{4}x^4(\ln x)^2 - \frac{1}{8}x^4 \ln x + \frac{1}{32}x^4 + C}.\end{aligned}$$

27. We use integration by parts with $u = \tan^{-1} x$ and $dv = x^2 dx$. Then $du = \frac{1}{1+x^2} dx$ and $v = \frac{1}{3}x^3$. We obtain

$$\begin{aligned}\int x^2 \tan^{-1} x dx &= (\tan^{-1} x) \left(\frac{1}{3}x^3 \right) - \int \left(\frac{1}{3}x^3 \right) \left(\frac{1}{1+x^2} \right) dx \\ &= \frac{1}{3}x^3 \tan^{-1} x - \frac{1}{3} \int \frac{x^3}{1+x^2} dx.\end{aligned}$$

Let $u = 1 + x^2$, then $du = 2x dx$, so $x dx = \frac{du}{2}$. Since $x^2 = u - 1$, we have $x^3 dx = \frac{u-1}{2} du$.

We substitute and obtain

$$\begin{aligned}
 \int x^2 \tan^{-1} x \, dx &= \frac{1}{3} x^3 \tan^{-1} x - \frac{1}{3} \int \frac{u^{-1}}{u} \, du \\
 &= \frac{1}{3} x^3 \tan^{-1} x - \frac{1}{6} \int \left(1 - \frac{1}{u}\right) \, du \\
 &= \frac{1}{3} x^3 \tan^{-1} x - \frac{1}{6} (u - \ln |u|) + C \\
 &= \frac{1}{3} x^3 \tan^{-1} x - \frac{1}{6} ((1 + x^2) - \ln |1 + x^2|) + C \\
 &= \boxed{\frac{1}{3} x^3 \tan^{-1} x - \frac{1}{6} x^2 + \frac{1}{6} \ln (1 + x^2) + C},
 \end{aligned}$$

where we have absorbed any constants with the constant C of integration.

28. We use integration by parts with $u = \tan^{-1} x$ and $dv = x \, dx$. Then $du = \frac{1}{1+x^2} \, dx$ and $v = \frac{1}{2} x^2$. We obtain

$$\begin{aligned}
 \int x \tan^{-1} x \, dx &= (\tan^{-1} x) \left(\frac{1}{2} x^2 \right) - \int \left(\frac{1}{2} x^2 \right) \left(\frac{1}{1+x^2} \right) \, dx \\
 &= \frac{1}{2} x^2 \tan^{-1} x - \frac{1}{2} \int \frac{x^2}{1+x^2} \, dx \\
 &= \frac{1}{2} x^2 \tan^{-1} x - \frac{1}{2} \int \frac{(1+x^2) - 1}{1+x^2} \, dx \\
 &= \frac{1}{2} x^2 \tan^{-1} x - \frac{1}{2} \int \left(1 - \frac{1}{1+x^2} \right) \, dx \\
 &= \frac{1}{2} x^2 \tan^{-1} x - \frac{1}{2} (x - \tan^{-1} x) + C \\
 &= \boxed{\frac{1}{2} x^2 \tan^{-1} x - \frac{1}{2} x + \frac{1}{2} \tan^{-1} x + C}.
 \end{aligned}$$

29. We use integration by parts with $u = x$ and $dv = 7^x \, dx$. Then $du = dx$ and $v = \frac{7^x}{\ln 7}$. We obtain

$$\begin{aligned}
 \int 7^x x \, dx &= (x) \left(\frac{7^x}{\ln 7} \right) - \int \frac{7^x}{\ln 7} \, dx \\
 &= \frac{7^x x}{\ln 7} - \frac{1}{\ln 7} \int 7^x \, dx \\
 &= \frac{7^x x}{\ln 7} - \frac{1}{\ln 7} \left(\frac{7^x}{\ln 7} \right) + C \\
 &= \boxed{\frac{7^x x}{\ln 7} - \frac{7^x}{(\ln 7)^2} + C}.
 \end{aligned}$$

30. We use integration by parts with $u = x$ and $dv = 2^{-x} dx$. Then $du = dx$ and $v = -\frac{2^{-x}}{\ln 2}$. We obtain

$$\begin{aligned}\int 2^{-x} x dx &= (x) \left(-\frac{2^{-x}}{\ln 2} \right) - \int \left(-\frac{2^{-x}}{\ln 2} \right) dx \\ &= -\frac{2^{-x} x}{\ln 2} + \frac{1}{\ln 2} \int 2^{-x} dx \\ &= -\frac{2^{-x} x}{\ln 2} + \frac{1}{\ln 2} \left(-\frac{2^{-x}}{\ln 2} \right) + C \\ &= \boxed{-\frac{2^{-x} x}{\ln 2} - \frac{2^{-x}}{(\ln 2)^2} + C}.\end{aligned}$$

31. We use integration by parts with $u = e^x$ and $dv = \cos x dx$. Then $du = e^x dx$ and $v = \sin x$. We obtain

$$\begin{aligned}\int_0^\pi e^x \cos x dx &= [e^x \sin x]_0^\pi - \int_0^\pi e^x \sin x dx \\ &= [e^\pi \sin \pi - e^0 \sin 0] - \int_0^\pi e^x \sin x dx \\ &= [e^\pi(0) - 1(0)] - \int_0^\pi e^x \sin x dx \\ &= -\int_0^\pi e^x \sin x dx.\end{aligned}$$

We use integration by parts again with $u = e^x$ and $dv = \sin x dx$. Then $du = e^x dx$ and $v = -\cos x$. We obtain

$$\begin{aligned}\int_0^\pi e^x \cos x dx &= -\left([e^x(-\cos x)]_0^\pi - \int_0^\pi e^x(-\cos x) dx \right) \\ &= -\left([e^\pi(-\cos \pi) - e^0(-\cos 0)] + \int_0^\pi e^x \cos x dx \right) \\ &= -\left([e^\pi(1) - 1(-1)] + \int_0^\pi e^x \cos x dx \right) \\ &= -e^\pi - 1 - \int_0^\pi e^x \cos x dx.\end{aligned}$$

We add $\int_0^\pi e^x \cos x dx$ to each side, and then divide by 2 to obtain

$$\begin{aligned}2 \int_0^\pi e^x \cos x dx &= -e^\pi - 1 \\ \int_0^\pi e^x \cos x dx &= \frac{-e^\pi - 1}{2} = \boxed{-\frac{e^\pi + 1}{2}}.\end{aligned}$$

32. We use integration by parts with $u = x^2$ and $dv = e^{-x} dx$. Then $du = 2x dx$ and $v = -e^{-x}$. We obtain

$$\begin{aligned}\int_0^1 x^2 e^{-x} dx &= [x^2(-e^{-x})]_0^1 - \int_0^1 (-e^{-x})(2x) dx \\ &= [1^2(-e^{-1}) - 0^2(-e^{-0})] + 2 \int_0^1 x e^{-x} dx \\ &= -e^{-1} + 2 \int_0^1 x e^{-x} dx.\end{aligned}$$

We use integration by parts again with $u = x$ and $dv = e^{-x}dx$. Then $du = dx$ and $v = -e^{-x}$. We obtain

$$\begin{aligned}
 \int_0^1 x^2 e^{-x} dx &= -e^{-1} + 2 \left([x(-e^{-x})]_0^1 - \int_0^1 (-e^{-x}) dx \right) \\
 &= -e^{-1} + 2 \left([1(-e^{-1}) - 0(-e^{-0})] + \int_0^1 e^{-x} dx \right) \\
 &= -e^{-1} + 2 \left(-e^{-1} + [-e^{-x}]_0^1 \right) \\
 &= -e^{-1} + 2(-e^{-1} + [-e^{-1} - (-e^{-0})]) \\
 &= \boxed{2 - 5e^{-1}}.
 \end{aligned}$$

33. We use integration by parts with $u = x^2$ and $dv = e^{-3x} dx$. Then $du = 2x dx$ and $v = -\frac{1}{3}e^{-3x}$. We obtain

$$\begin{aligned}
 \int_0^2 x^2 e^{-3x} dx &= \left[x^2 \left(-\frac{1}{3} e^{-3x} \right) \right]_0^2 - \int_0^2 \left(-\frac{1}{3} e^{-3x} \right) (2x) dx \\
 &= \left[2^2 \left(-\frac{1}{3} e^{-3(2)} \right) - 0^2 \left(-\frac{1}{3} e^{-3(0)} \right) \right] + \frac{2}{3} \int_0^2 x e^{-3x} dx \\
 &= -\frac{4}{3} e^{-6} + \frac{2}{3} \int_0^2 x e^{-3x} dx.
 \end{aligned}$$

We use integration by parts again with $u = x$ and $dv = e^{-3x} dx$. Then $du = dx$ and $v = -\frac{1}{3}e^{-3x}$. We obtain

$$\begin{aligned}
 \int_0^2 x^2 e^{-3x} dx &= -\frac{4}{3} e^{-6} + \frac{2}{3} \left(\left[x \left(-\frac{1}{3} e^{-3x} \right) \right]_0^2 - \int_0^2 \left(-\frac{1}{3} e^{-3x} \right) dx \right) \\
 &= -\frac{4}{3} e^{-6} + \frac{2}{3} \left(\left[2 \left(-\frac{1}{3} e^{-3(2)} \right) - 0 \left(-\frac{1}{3} e^{-3(0)} \right) \right] + \frac{1}{3} \int_0^2 e^{-3x} dx \right) \\
 &= -\frac{4}{3} e^{-6} + \frac{2}{3} \left(\left(-\frac{2}{3} e^{-6} \right) + \frac{1}{3} \left[-\frac{1}{3} e^{-3x} \right]_0^2 \right) \\
 &= -\frac{4}{3} e^{-6} + \frac{2}{3} \left(\left(-\frac{2}{3} e^{-6} \right) + \frac{1}{3} \left[-\frac{1}{3} e^{-3(2)} - \left(-\frac{1}{3} e^{-3(0)} \right) \right] \right) \\
 &= -\frac{4}{3} e^{-6} + \frac{2}{3} \left(\left(-\frac{2}{3} e^{-6} \right) + \frac{1}{3} \left(\frac{1}{3} - \frac{1}{3} e^{-6} \right) \right) \\
 &= \boxed{\frac{2}{27} - \frac{50}{27} e^{-6}}.
 \end{aligned}$$

34. We use integration by parts with $u = x$ and $dv = \tan^2 x \, dx = (\sec^2 x - 1) \, dx$. Then $du = dx$ and $v = \tan x - x$. We obtain

$$\begin{aligned}
 \int_0^{\pi/4} x \tan^2 x \, dx &= [x(\tan x - x)]_0^{\pi/4} - \int_0^{\pi/4} (\tan x - x) \, dx \\
 &= \left[\frac{\pi}{4} \left(\tan \frac{\pi}{4} - \frac{\pi}{4} \right) - 0(\tan 0 - 0) \right] - \left[\ln |\sec x| - \frac{1}{2} x^2 \right]_0^{\pi/4} \\
 &= \frac{\pi}{4} - \frac{\pi^2}{16} - \left[\ln \left| \sec \frac{\pi}{4} \right| - \frac{1}{2} \left(\frac{\pi}{4} \right)^2 - \left(\ln |\sec 0| - \frac{1}{2} 0^2 \right) \right] \\
 &= \frac{\pi}{4} - \frac{\pi^2}{16} - \left(\ln \sqrt{2} - \frac{\pi^2}{32} \right) \\
 &= \boxed{\frac{\pi}{4} - \frac{\pi^2}{32} - \frac{1}{2} \ln 2}.
 \end{aligned}$$

35. We rewrite $\int_1^9 \ln \sqrt{x} \, dx = \int_1^9 \ln x^{1/2} \, dx = \frac{1}{2} \int_1^9 \ln x \, dx$. We use integration by parts with $u = \ln x$ and $dv = dx$. Then $du = \frac{1}{x} \, dx$ and $v = x$. We obtain

$$\begin{aligned}
 \int_1^9 \ln \sqrt{x} \, dx &= \frac{1}{2} \int_1^9 \ln x \, dx \\
 &= \frac{1}{2} \left([(\ln x)(x)]_1^9 - \int_1^9 x \left(\frac{1}{x} \right) dx \right) \\
 &= \frac{1}{2} \left([(\ln 9)(9) - (\ln 1)(1)] - \int_1^9 dx \right) \\
 &= \frac{1}{2} (9 \ln 9 - 8) \\
 &= \boxed{9 \ln 3 - 4}.
 \end{aligned}$$

36. We use integration by parts with $u = x$ and $dv = \csc^2 x \, dx$. Then $du = dx$ and $v = -\cot x$. We obtain

$$\begin{aligned}
 \int_{\pi/4}^{3\pi/4} x \csc^2 x \, dx &= [x(-\cot x)]_{\pi/4}^{3\pi/4} - \int_{\pi/4}^{3\pi/4} (-\cot x) \, dx \\
 &= \left[\frac{3\pi}{4} \left(-\cot \frac{3\pi}{4} \right) - \frac{\pi}{4} \left(-\cot \frac{\pi}{4} \right) \right] + \int_{\pi/4}^{3\pi/4} \cot x \, dx \\
 &= \left(\frac{3\pi}{4} + \frac{\pi}{4} \right) + [\ln |\sin x|]_{\pi/4}^{3\pi/4} \\
 &= \pi + \left[\ln \left| \sin \frac{3\pi}{4} \right| - \ln \left| \sin \frac{\pi}{4} \right| \right] \\
 &= \pi + \left(\ln \frac{\sqrt{2}}{2} - \ln \frac{\sqrt{2}}{2} \right) \\
 &= \boxed{\pi}.
 \end{aligned}$$

37. We use integration by parts with $u = (\ln x)^2$ and $dv = dx$. Then $du = 2\frac{\ln x}{x} dx$ and $v = x$. We obtain

$$\begin{aligned}\int_1^e (\ln x)^2 dx &= \left[(\ln x)^2(x) \right]_1^e - \int_1^e x \left(2\frac{\ln x}{x} \right) dx \\ &= (\ln e)^2(e) - (\ln 1)^2(1) - \int_1^e 2 \ln x dx \\ &= e - 2 \int_1^e \ln x dx.\end{aligned}$$

We use integration by parts again with $u = \ln x$ and $dv = dx$. Then $du = \frac{1}{x} dx$ and $v = x$. We obtain

$$\begin{aligned}\int_1^e (\ln x)^2 dx &= e - 2 \left([(\ln x)x]_1^e - \int_1^e x \frac{1}{x} dx \right) \\ &= e - 2 \left((\ln e)e - (\ln 1)(1) - \int_1^e dx \right) \\ &= e - 2(e - (e - 1)) \\ &= \boxed{e - 2}.\end{aligned}$$

38. We use integration by parts with $u = x$ and $dv = \sec^2 x dx$. Then $du = dx$ and $v = \tan x$. We obtain

$$\begin{aligned}\int_0^{\pi/4} x \sec^2 x dx &= [x(\tan x)]_0^{\pi/4} - \int_0^{\pi/4} \tan x dx \\ &= \left[\frac{\pi}{4} \left(\tan \frac{\pi}{4} \right) - 0(\tan 0) \right] - [\ln |\sec x|]_0^{\pi/4} \\ &= \frac{\pi}{4} - [\ln |\sec \frac{\pi}{4}| - \ln |\sec 0|] \\ &= \frac{\pi}{4} - \ln \sqrt{2} \\ &= \boxed{\frac{\pi}{4} - \frac{1}{2} \ln 2}.\end{aligned}$$

39. To determine where the graphs intersect, set $3 \ln x = x \ln x$, and obtain $x = 3$. Since $\ln x \geq 0$ when $1 \leq x \leq 3$, we have $x \ln x \leq 3 \ln x$ on the interval $1 \leq x \leq 3$ and the area enclosed by the graphs of f and g is

$$\int_1^3 (3 \ln x - x \ln x) dx = \int_1^3 (3 - x) \ln x dx.$$

We use integration by parts with $u = \ln x$ and $dv = (3 - x) dx$. Then $du = \frac{1}{x} dx$ and $v = 3x - \frac{1}{2}x^2$. We obtain

$$\begin{aligned}\int_1^3 (3 - x) \ln x dx &= \left[(\ln x) \left(3x - \frac{1}{2}x^2 \right) \right]_1^3 - \int_1^3 \frac{3x - \frac{1}{2}x^2}{x} dx \\ &= \left[(\ln 3) \left(3(3) - \frac{1}{2}3^2 \right) - (\ln 1) \left(3(1) - \frac{1}{2}1^2 \right) \right] - \int_1^3 \left(3 - \frac{1}{2}x \right) dx \\ &= \frac{9}{2} \ln 3 - \left[3x - \frac{1}{4}x^2 \right]_1^3 \\ &= \frac{9}{2} \ln 3 - \left[\left(3(3) - \frac{1}{4}3^2 \right) - \left(3(1) - \frac{1}{4}1^2 \right) \right] \\ &= \boxed{\frac{9}{2} \ln 3 - 4}.\end{aligned}$$

40. To determine where the graphs intersect, set $4x \ln x = x^2 \ln x$, and obtain $x = 1$ and $x = 4$. Since $\ln x \geq 0$ when $1 \leq x \leq 4$, we have $x^2 \ln x \leq 4x \ln x$ on the interval $1 \leq x \leq 4$, and the area enclosed by the graphs of f and g is

$$\int_1^4 (4x \ln x - x^2 \ln x) dx = \int_1^4 (4x - x^2) \ln x dx.$$

We use integration by parts with $u = \ln x$ and $dv = (4x - x^2) dx$. Then $du = \frac{1}{x} dx$ and $v = 2x^2 - \frac{1}{3}x^3$. We obtain

$$\begin{aligned} \int_1^4 (4x - x^2) \ln x dx &= \left[(\ln x) \left(2x^2 - \frac{1}{3}x^3 \right) \right]_1^4 - \int_1^4 \frac{2x^2 - \frac{1}{3}x^3}{x} dx \\ &= \left[(\ln 4) \left(2(4)^2 - \frac{1}{3}4^3 \right) - (\ln 1) \left(2(1)^2 - \frac{1}{3}1^3 \right) \right] - \int_1^4 \left(2x - \frac{1}{3}x^2 \right) dx \\ &= \frac{32}{3} \ln 4 - \left[x^2 - \frac{1}{9}x^3 \right]_1^4 \\ &= \frac{32}{3} \ln 4 - \left[\left(4^2 - \frac{1}{9}4^3 \right) - \left(1^2 - \frac{1}{9}1^3 \right) \right] \\ &= \boxed{\frac{32}{3} \ln 4 - 8}. \end{aligned}$$

41. The area under the graph of $y = e^x \sin x$ from 0 to π is given by $\int_0^\pi e^x \sin x dx$. We use integration by parts with $u = e^x$ and $dv = \sin x dx$. Then $du = e^x dx$ and $v = -\cos x$. We obtain

$$\begin{aligned} \int_0^\pi e^x \sin x dx &= [e^x(-\cos x)]_0^\pi - \int_0^\pi e^x(-\cos x) dx \\ &= [e^\pi(-\cos \pi) - e^0(-\cos 0)] + \int_0^\pi e^x \cos x dx \\ &= e^\pi + 1 + \int_0^\pi e^x \cos x dx. \end{aligned}$$

We use integration by parts again with $u = e^x$ and $dv = \cos x dx$. Then $du = e^x dx$ and $v = \sin x$. We obtain

$$\begin{aligned} \int_0^\pi e^x \sin x dx &= e^\pi + 1 + [e^x \sin x]_0^\pi - \int_0^\pi e^x \sin x dx \\ &= e^\pi + 1 + (e^\pi \sin \pi - e^0 \sin 0) - \int_0^\pi e^x \sin x dx \\ &= e^\pi + 1 - \int_0^\pi e^x \sin x dx \end{aligned}$$

We add $\int_0^\pi e^x \sin x dx$ to each side, and then divide by 2 to obtain

$$\begin{aligned} 2 \int_0^\pi e^x \sin x dx &= e^\pi + 1 \\ \int_0^\pi e^x \sin x dx &= \boxed{\frac{e^\pi + 1}{2}}. \end{aligned}$$

42. The volume is given by the integral $\int_0^{\pi/2} 2\pi x \cos x \, dx$. We use integration by parts with $u = 2\pi x$ and $dv = \cos x \, dx$. Then $du = 2\pi \, dx$ and $v = \sin x$. We obtain

$$\begin{aligned} \int_0^{\pi/2} 2\pi x \cos x \, dx &= [(2\pi x)(\sin x)]_0^{\pi/2} - \int_0^{\pi/2} \sin x (2\pi) \, dx \\ &= \left[\left(2\pi \left(\frac{\pi}{2} \right) \right) \left(\sin \frac{\pi}{2} \right) - (2\pi(0))(\sin 0) \right] - 2\pi \int_0^{\pi/2} \sin x \, dx \\ &= \pi^2 - 2\pi [-\cos x]_0^{\pi/2} \\ &= \pi^2 - 2\pi \left[-\cos \frac{\pi}{2} - (-\cos 0) \right] \\ &= \boxed{\pi^2 - 2\pi}. \end{aligned}$$

43. The volume is given by the integral $\int_0^{\pi/2} 2\pi x \sin x \, dx$. We use integration by parts with $u = 2\pi x$ and $dv = \sin x \, dx$. Then $du = 2\pi \, dx$ and $v = -\cos x$. We obtain

$$\begin{aligned} \int_0^{\pi/2} 2\pi x \sin x \, dx &= [(2\pi x)(-\cos x)]_0^{\pi/2} - \int_0^{\pi/2} (-\cos x)(2\pi) \, dx \\ &= \left[\left(2\pi \left(\frac{\pi}{2} \right) \right) \left(-\cos \frac{\pi}{2} \right) - (2\pi(0))(-\cos 0) \right] + 2\pi \int_0^{\pi/2} \cos x \, dx \\ &= 2\pi \int_0^{\pi/2} \cos x \, dx \\ &= 2\pi [\sin x]_0^{\pi/2} \\ &= 2\pi \left[\sin \frac{\pi}{2} - \sin 0 \right] \\ &= \boxed{2\pi}. \end{aligned}$$

44. The volume is given by the integral $\int_0^{\pi/2} \pi \left(x\sqrt{\sin x} \right)^2 \, dx = \int_0^{\pi/2} \pi x^2 \sin x \, dx$. We use integration by parts with $u = \pi x^2$ and $dv = \sin x \, dx$. Then $du = 2\pi x \, dx$ and $v = -\cos x$. We obtain

$$\begin{aligned} \int_0^{\pi/2} \pi x^2 \sin x \, dx &= [(\pi x^2)(-\cos x)]_0^{\pi/2} - \int_0^{\pi/2} (-\cos x)(2\pi x) \, dx \\ &= \left[\left(\pi \left(\frac{\pi}{2} \right)^2 \right) \left(-\cos \left(\frac{\pi}{2} \right) \right) - (\pi 0^2)(-\cos 0) \right] + \int_0^{\pi/2} 2\pi x \cos x \, dx \\ &= \int_0^{\pi/2} 2\pi x \cos x \, dx. \end{aligned}$$

We use integration by parts again with $u = 2\pi x$ and $dv = \cos x \, dx$. Then $du = 2\pi \, dx$ and $v = \sin x$. We obtain

$$\begin{aligned} \int_0^{\pi/2} \pi x^2 \sin x \, dx &= [(2\pi x)(\sin x)]_0^{\pi/2} - \int_0^{\pi/2} (\sin x)(2\pi) \, dx \\ &= \left[\left(2\pi \left(\frac{\pi}{2} \right) \right) \left(\sin \left(\frac{\pi}{2} \right) \right) - (2\pi(0))(\sin 0) \right] - 2\pi \int_0^{\pi/2} \sin x \, dx \\ &= \pi^2 - 2\pi [-\cos x]_0^{\pi/2} \\ &= \pi^2 - 2\pi \left[-\cos \frac{\pi}{2} - (-\cos 0) \right] \\ &= \boxed{\pi^2 - 2\pi}. \end{aligned}$$

45. The volume is given by the integral $\int_1^e \pi(\ln x)^2 dx$. We use integration by parts with $u = (\ln x)^2$ and $dv = \pi dx$. Then $du = \frac{2\ln x}{x} dx$ and $v = \pi x$. We obtain

$$\begin{aligned}\int_1^e \pi(\ln x)^2 dx &= \left[(\ln x)^2 (\pi x) \right]_1^e - \int_1^e (\pi x) \left(\frac{2\ln x}{x} \right) dx \\ &= \left[(\ln e)^2 (\pi e) - (\ln 1)^2 (\pi 1) \right] - 2\pi \int_1^e \ln x dx \\ &= \pi e - 2\pi \int_1^e \ln x dx.\end{aligned}$$

We use integration by parts again with $u = \ln x$ and $dv = dx$. Then $du = \frac{1}{x} dx$ and $v = x$. We obtain

$$\begin{aligned}\int_1^e \pi(\ln x)^2 dx &= \pi e - 2\pi \left([(\ln x)x]_1^e - \int_1^e x \left(\frac{1}{x} \right) dx \right) \\ &= \pi e - 2\pi \left([(\ln e)e - (\ln 1)1] - \int_1^e dx \right) \\ &= \pi e - 2\pi(e - (e - 1)) \\ &= \boxed{\pi e - 2\pi}.\end{aligned}$$

46. (a)

- (b) The area enclosed by the graphs of f and g is given by $\int_0^1 (x^2 e^{-3x} - x^3 e^{-3x}) dx = \int_0^1 (x^2 - x^3) e^{-3x} dx$. We use integration by parts with $u = x^2 - x^3$ and $dv = e^{-3x} dx$. Then $du = (2x - 3x^2) dx$ and $v = -\frac{1}{3} e^{-3x}$. We obtain

$$\begin{aligned}\int_0^1 (x^2 - x^3) e^{-3x} dx &= \left[(x^2 - x^3) \left(-\frac{1}{3} e^{-3x} \right) \right]_0^1 - \int_0^1 \left(-\frac{1}{3} e^{-3x} \right) (2x - 3x^2) dx \\ &= \left[(1^2 - 1^3) \left(-\frac{1}{3} e^{-3(1)} \right) - (0^2 - 0^3) \left(-\frac{1}{3} e^{-3(0)} \right) \right] \\ &\quad + \frac{1}{3} \int_0^1 (2x - 3x^2) e^{-3x} dx \\ &= \frac{1}{3} \int_0^1 (2x - 3x^2) e^{-3x} dx.\end{aligned}$$

We use integration by parts again with $u = 2x - 3x^2$ and $dv = e^{-3x} dx$. Then

$du = (2 - 6x) dx$ and $v = -\frac{1}{3}e^{-3x}$. We obtain

$$\begin{aligned}\int_0^1 (x^2 - x^3)e^{-3x} dx &= \frac{1}{3} \left(\left[(2x - 3x^2) \left(-\frac{1}{3}e^{-3x} \right) \right]_0^1 - \int_0^1 \left(-\frac{1}{3}e^{-3x} \right) (2 - 6x) dx \right) \\ &= \frac{1}{3} \left[(2(1) - 3(1)^2) \left(-\frac{1}{3}e^{-3(1)} \right) - (2(0) - 3(0)^2) \left(-\frac{1}{3}e^{-3(0)} \right) \right] \\ &\quad + \frac{2}{9} \int_0^1 (1 - 3x)e^{-3x} dx \\ &= \frac{1}{9}e^{-3} + \frac{2}{9} \int_0^1 (1 - 3x)e^{-3x} dx.\end{aligned}$$

We use integration by parts again with $u = 1 - 3x$ and $dv = e^{-3x} dx$. Then $du = -3 dx$ and $v = -\frac{1}{3}e^{-3x}$. We obtain

$$\begin{aligned}\int_0^1 (x^2 - x^3)e^{-3x} dx &= \frac{1}{9}e^{-3} + \frac{2}{9} \left(\left[(1 - 3x) \left(-\frac{e^{-3x}}{3} \right) \right]_0^1 - \int_0^1 \left(-\frac{e^{-3x}}{3} \right) (-3) dx \right) \\ &= \frac{1}{9}e^{-3} + \frac{2}{9} \left[(1 - 3(1)) \left(-\frac{e^{-3(1)}}{3} \right) - (1 - 3(0)) \left(-\frac{e^{-3(0)}}{3} \right) \right] \\ &\quad - \frac{2}{9} \int_0^1 e^{-3x} dx \\ &= \frac{7}{27}e^{-3} + \frac{2}{27} - \frac{2}{9} \left[-\frac{1}{3}e^{-3x} \right]_0^1 \\ &= \frac{7}{27}e^{-3} + \frac{2}{27} - \frac{2}{9} \left[-\frac{1}{3}e^{-3(1)} - \left(-\frac{1}{3}e^{-3(0)} \right) \right] \\ &= \boxed{\frac{1}{3}e^{-3}}.\end{aligned}$$

47. (a)

(b) Set $3e^{-t} \cos(2t) + 2e^{-t} \sin(2t) = 0$ and solve for t . We obtain $\tan(2t) = -\frac{3}{2}$, so $2t = \tan^{-1}\left(-\frac{3}{2}\right) + k\pi$, where k is any integer. So the least positive number t such that $x(t) = 0$ is $t = \boxed{\frac{\pi}{2} + \frac{1}{2} \tan^{-1}\left(-\frac{3}{2}\right)}$.

(c) We integrate $\int_0^{\frac{\pi}{2} - \frac{1}{2} \tan^{-1}\left(\frac{3}{2}\right)} 3e^{-t} \cos(2t) + 2e^{-t} \sin(2t) dt$ using a Computer Algebra System, and we obtain $\int_0^{\frac{\pi}{2} - \frac{1}{2} \tan^{-1}\left(\frac{3}{2}\right)} (3e^{-t} \cos(2t) + 2e^{-t} \sin(2t)) dt \approx \boxed{1.890}$.

48. We use integration by parts, with $u = x$ and $dv = f'(x) dx$. Then $du = dx$ and $v = f(x)$. We obtain

$$\begin{aligned}\int_3^5 x f'(x) dx &= [x f(x)]_3^5 - \int_3^5 f(x) dx \\ &= 5f(5) - 3f(3) - (18) \\ &= 5(11) - 3(8) - 18 \\ &= \boxed{13}.\end{aligned}$$

49. Let $w = \sqrt{x}$, then $dw = \frac{1}{2\sqrt{x}} dx$, so $dx = 2w dw$. We substitute and obtain

$$\int \sin \sqrt{x} dx = \int 2w \sin w dw.$$

We use integration by parts, with $u = 2w$ and $dv = \sin w dw$. Then $du = 2 dw$ and $v = -\cos w$. We obtain

$$\begin{aligned}\int 2w \sin w dw &= (2w)(-\cos w) - \int (-\cos w)(2) dw \\ &= -2w \cos w + 2 \int \cos w dw \\ &= -2w \cos w + 2(\sin w) + C \\ &= \boxed{-2\sqrt{x} \cos \sqrt{x} + 2 \sin \sqrt{x} + C}.\end{aligned}$$

50. Let $w = \sqrt{x}$, then $dw = \frac{1}{2\sqrt{x}} dx$, so $dx = 2w dw$. We substitute and obtain

$$\int e^{\sqrt{x}} dx = \int 2w e^w dw.$$

We use integration by parts, with $u = 2w$ and $dv = e^w dw$. Then $du = 2 dw$ and $v = e^w$. We obtain

$$\begin{aligned}\int 2w e^w dw &= (2w)(e^w) - \int (e^w)(2) dw \\ &= 2w e^w - 2 \int e^w dw \\ &= 2w e^w - 2(e^w) + C \\ &= \boxed{2\sqrt{x} e^{\sqrt{x}} - 2e^{\sqrt{x}} + C}.\end{aligned}$$

51. Let $w = \sin x$, then $dw = \cos x dx$. We substitute and obtain

$$\int \cos x \ln(\sin x) dx = \int \ln w dw.$$

We use integration by parts, with $u = \ln w$ and $dv = dw$. Then $du = \frac{1}{w} dw$ and $v = w$. We obtain

$$\begin{aligned}\int \ln w dw &= (\ln w)(w) - \int (w) \left(\frac{1}{w} \right) dw \\ &= w \ln w - \int dw \\ &= w \ln w - w + C \\ &= \boxed{\sin x \ln(\sin x) - \sin x + C}.\end{aligned}$$

52. Let $w = 2 + e^x$, then $dw = e^x dx$. We substitute and obtain

$$\int e^x \ln(2 + e^x) dx = \int \ln w dw.$$

We use integration by parts, with $u = \ln w$ and $dv = dw$. Then $du = \frac{1}{w} dw$ and $v = w$. We obtain

$$\begin{aligned} \int \ln w dw &= (\ln w)(w) - \int (w) \left(\frac{1}{w} \right) dw \\ &= w \ln w - \int dw \\ &= w \ln w - w + C \\ &= (2 + e^x) \ln(2 + e^x) - 2 - e^x + C \\ &= \boxed{(2 + e^x) \ln(2 + e^x) - e^x + C}, \end{aligned}$$

where we have absorbed any constants with the constant C of integration.

53. Let $w = e^{2x}$, then $dw = 2e^{2x} dx$, so $e^{2x} dx = \frac{1}{2} dw$. We substitute and obtain

$$\int e^{4x} \cos(e^{2x}) dx = \int e^{2x} \cos(e^{2x}) e^{2x} dx = \int w \cos w \left(\frac{1}{2} dw \right) = \int \frac{1}{2} w \cos w dw.$$

We use integration by parts, with $u = \frac{1}{2}w$ and $dv = \cos w dw$. Then $du = \frac{1}{2} dw$ and $v = \sin w$. We obtain

$$\begin{aligned} \int \frac{1}{2} w \cos w dw &= \left(\frac{1}{2} w \right) (\sin w) - \int (\sin w) \left(\frac{1}{2} \right) dw \\ &= \frac{1}{2} w \sin w - \frac{1}{2} \int \sin w dw \\ &= \frac{1}{2} w \sin w - \frac{1}{2} (-\cos w) + C \\ &= \frac{1}{2} w \sin w + \frac{1}{2} \cos w + C \\ &= \boxed{\frac{1}{2} e^{2x} \sin(e^{2x}) + \frac{1}{2} \cos(e^{2x}) + C}. \end{aligned}$$

54. Let $w = \sin x$, then $dw = \cos x dx$. We substitute and obtain

$$\int \cos x \tan^{-1}(\sin x) dx = \int \tan^{-1} w dw.$$

We use integration by parts with $u = \tan^{-1} w$ and $dv = dw$. Then $du = \frac{1}{1+w^2} dw$ and $v = w$. We obtain

$$\begin{aligned} \int \tan^{-1} w dw &= (\tan^{-1} w)(w) - \int (w) \left(\frac{1}{1+w^2} \right) dw \\ &= w \tan^{-1} w - \int \frac{w}{1+w^2} dw. \end{aligned}$$

Let $y = 1 + w^2$, then $dy = 2w dw$, so $w dw = \frac{1}{2} dy$. We substitute and obtain

$$\begin{aligned}
 \int \tan^{-1} w dw &= w \tan^{-1} w - \int \frac{1}{y} \left(\frac{1}{2} dy \right) \\
 &= w \tan^{-1} w - \frac{1}{2} \int \frac{1}{y} dy \\
 &= w \tan^{-1} w - \frac{1}{2} \ln |y| + C \\
 &= w \tan^{-1} w - \frac{1}{2} \ln (1 + w^2) + C \\
 &= \boxed{\sin x \tan^{-1} (\sin x) - \frac{1}{2} \ln (1 + \sin^2 x) + C}.
 \end{aligned}$$

55. We use integration by parts with $u = x^2$ and $dv = xe^{x^2} dx$. Then $du = 2x dx$ and $v = \frac{1}{2}e^{x^2}$. We obtain

$$\begin{aligned}
 \int x^3 e^{x^2} dx &= (x^2) \left(\frac{1}{2} e^{x^2} \right) - \int \left(\frac{1}{2} e^{x^2} \right) (2x) dx \\
 &= \frac{1}{2} x^2 e^{x^2} - \int x e^{x^2} dx \\
 &= \boxed{\frac{1}{2} x^2 e^{x^2} - \frac{1}{2} e^{x^2} + C}.
 \end{aligned}$$

56. We use integration by parts with $u = \ln x$ and $dv = x^n dx$. Then $du = \frac{1}{x} dx$ and $v = \frac{1}{n+1} x^{n+1}$. We obtain

$$\begin{aligned}
 \int x^n \ln x dx &= (\ln x) \left(\frac{1}{n+1} x^{n+1} \right) - \int \left(\frac{1}{n+1} x^{n+1} \right) \left(\frac{1}{x} \right) dx \\
 &= \frac{1}{n+1} x^{n+1} \ln x - \frac{1}{n+1} \int x^n dx \\
 &= \frac{1}{n+1} x^{n+1} \ln x - \frac{1}{n+1} \left(\frac{x^{n+1}}{n+1} \right) + C \\
 &= \boxed{\frac{1}{n+1} x^{n+1} \ln x - \frac{1}{(n+1)^2} x^{n+1} + C}.
 \end{aligned}$$

57. We use integration by parts with $u = x \cos x$ and $dv = e^x dx$. Then $du = (-x \sin x + \cos x) dx$ and $v = e^x$. We obtain

$$\int x e^x \cos x dx = (x \cos x) e^x - \int (-x \sin x + \cos x) e^x dx.$$

We use integration by parts again with $u = -x \sin x + \cos x$ and $dv = e^x dx$. Then $du = (-2 \sin x - x \cos x) dx$ and $v = e^x$. We obtain

$$\begin{aligned}
 \int x e^x \cos x dx &= (x \cos x) e^x - \left((-x \sin x + \cos x) e^x - \int (-2 \sin x - x \cos x) e^x dx \right) \\
 &= x \cos x e^x + x \sin x e^x - \cos x e^x - 2 \int \sin x e^x dx - \int x \cos x e^x dx.
 \end{aligned}$$

We add $\int x e^x \cos x dx$ to each side and divide by 2 to obtain

$$\begin{aligned}
 2 \int x e^x \cos x dx &= x \cos x e^x + x \sin x e^x - \cos x e^x - 2 \int \sin x e^x dx \\
 \int x e^x \cos x dx &= \frac{1}{2} (x \cos x e^x + x \sin x e^x - \cos x e^x) - \int \sin x e^x dx.
 \end{aligned}$$

We determine $\int \sin x e^x dx$ using integration by parts. Let $u = \sin x$ and $dv = e^x dx$. Then $du = \cos x dx$ and $v = e^x$. We obtain

$$\int \sin x e^x dx = (\sin x)e^x - \int (\cos x)e^x dx.$$

We integrate by parts again with $u = \cos x$ and $dv = e^x dx$. Then $du = -\sin x dx$ and $v = e^x$. We obtain

$$\begin{aligned} \int \sin x e^x dx &= \sin x e^x - \left[(\cos x)e^x - \int (-\sin x)e^x dx \right] \\ &= \sin x e^x - \cos x e^x - \int \sin x e^x dx. \end{aligned}$$

We add $\int (\sin x)e^x dx$ to each side and divide by 2 to obtain

$$\begin{aligned} 2 \int \sin x e^x dx &= \sin x e^x - \cos x e^x \\ \int \sin x e^x dx &= \frac{1}{2} \sin x e^x - \frac{1}{2} \cos x e^x + C. \end{aligned}$$

We substitute into the above to obtain

$$\begin{aligned} \int x e^x \cos x dx &= \frac{1}{2}(x \cos x e^x + x \sin x e^x - \cos x e^x) - \left(\frac{1}{2} \sin x e^x - \frac{1}{2} \cos x e^x \right) + C \\ &= \frac{1}{2} x \cos x e^x + \frac{1}{2} x \sin x e^x - \frac{1}{2} \sin x e^x + C \\ &= \boxed{\frac{1}{2} e^x (x \sin x + x \cos x - \sin x) + C}. \end{aligned}$$

58. We use integration by parts with $u = x \sin x$ and $dv = e^x dx$. Then $du = (x \cos x + \sin x) dx$ and $v = e^x$. We obtain

$$\int x e^x \sin x dx = (x \sin x)e^x - \int (x \cos x + \sin x)e^x dx.$$

We use integration by parts again with $u = x \cos x + \sin x$ and $dv = e^x dx$. Then $du = (-x \sin x + 2 \cos x) dx$ and $v = e^x$. We obtain

$$\begin{aligned} \int x e^x \sin x dx &= x \sin x e^x - \left((x \cos x + \sin x)e^x - \int (-x \sin x + 2 \cos x)e^x dx \right) \\ &= x \sin x e^x - x \cos x e^x - \sin x e^x - \int x \sin x e^x dx + 2 \int \cos x e^x dx. \end{aligned}$$

We add $\int x e^x \sin x dx$ to each side and divide by 2 to obtain

$$\begin{aligned} 2 \int x e^x \sin x dx &= x \sin x e^x - x \cos x e^x - \sin x e^x + 2 \int \cos x e^x dx \\ \int x e^x \sin x dx &= \frac{1}{2}(x \sin x e^x - x \cos x e^x - \sin x e^x) + \int \cos x e^x dx. \end{aligned}$$

We determine $\int \cos x e^x dx$ using integration by parts. Let $u = \cos x$ and $dv = e^x dx$. Then $du = -\sin x dx$ and $v = e^x$. We obtain

$$\int \cos x e^x dx = (\cos x)e^x - \int (-\sin x)e^x dx = \cos x e^x + \int \sin x e^x dx.$$

We integrate by parts again with $u = \sin x$ and $dv = e^x dx$. Then $du = \cos x dx$ and $v = e^x$. We obtain

$$\begin{aligned}\int \cos x e^x dx &= \cos x e^x + \left[(\sin x) e^x - \int (\cos x) e^x dx \right] \\ &= \cos x e^x + \sin x e^x - \int \cos x e^x dx.\end{aligned}$$

We add $\int \cos x e^x dx$ to each side and divide by 2 to obtain

$$\begin{aligned}2 \int \cos x e^x dx &= \cos x e^x + \sin x e^x \\ \int \cos x e^x dx &= \frac{1}{2} \cos x e^x + \frac{1}{2} \sin x e^x + C.\end{aligned}$$

We substitute into the above to obtain

$$\begin{aligned}\int x e^x \cos x dx &= \frac{1}{2} (x \sin x e^x - x \cos x e^x - \sin x e^x) + \left(\frac{1}{2} \cos x e^x + \frac{1}{2} \sin x e^x \right) + C \\ &= \boxed{\frac{1}{2} x \sin x e^x - \frac{1}{2} x \cos x e^x + \frac{1}{2} \cos x e^x + C}.\end{aligned}$$

59. We use integration by parts with $u = \sin^{-1} x$ and $dv = x^n dx$. Then $du = \frac{1}{\sqrt{1-x^2}} dx$ and $v = \frac{x^{n+1}}{n+1}$. We obtain

$$\int x^n \sin^{-1} x dx = \frac{x^{n+1}}{n+1} \sin^{-1} x - \frac{1}{n+1} \int \frac{x^{n+1}}{\sqrt{1-x^2}} dx.$$

60. We consider the integral $\int \frac{1}{(x^2+1)^n} dx$ and use integration by parts with $u = \frac{1}{(x^2+1)^n}$ and $dv = dx$. Then $du = \frac{-2nx}{(x^2+1)^{n+1}} dx$ and $v = x$. We obtain

$$\begin{aligned}\int \frac{1}{(x^2+1)^n} dx &= \frac{x}{(x^2+1)^n} - \int (x) \left(\frac{-2nx}{(x^2+1)^{n+1}} \right) dx \\ &= \frac{x}{(x^2+1)^n} + 2n \int \frac{x^2}{(x^2+1)^{n+1}} dx \\ &= \frac{x}{(x^2+1)^n} + 2n \int \frac{(x^2+1) - 1}{(x^2+1)^{n+1}} dx \\ &= \frac{x}{(x^2+1)^n} + 2n \int \frac{1}{(x^2+1)^n} dx - 2n \int \frac{1}{(x^2+1)^{n+1}} dx.\end{aligned}$$

We solve for $\int \frac{1}{(x^2+1)^{n+1}} dx$, and obtain

$$\begin{aligned}2n \int \frac{1}{(x^2+1)^{n+1}} dx &= \frac{x}{(x^2+1)^n} + 2n \int \frac{1}{(x^2+1)^n} dx - \int \frac{1}{(x^2+1)^n} dx \\ 2n \int \frac{1}{(x^2+1)^{n+1}} dx &= \frac{x}{(x^2+1)^n} + (2n-1) \int \frac{1}{(x^2+1)^n} dx \\ \int \frac{1}{(x^2+1)^{n+1}} dx &= \frac{x}{2n(x^2+1)^n} + \left(1 - \frac{1}{2n} \right) \int \frac{1}{(x^2+1)^n} dx.\end{aligned}$$

61. We use integration by parts with $u = \sin^{n-1} x$ and $dv = \sin x dx$. Then $du = (n-1) \sin^{n-2} x \cos x dx$ and $v = -\cos x$. We obtain

$$\begin{aligned}
 \int \sin^n x dx &= \sin^{n-1} x (-\cos x) - \int (-\cos x)(n-1) \sin^{n-2} x \cos x dx \\
 &= -\sin^{n-1} x \cos x + (n-1) \int \cos^2 x \sin^{n-2} x dx \\
 &= -\sin^{n-1} x \cos x + (n-1) \int (1 - \sin^2 x) \sin^{n-2} x dx \\
 &= -\sin^{n-1} x \cos x + (n-1) \left(\int \sin^{n-2} x dx - \int \sin^n x dx \right) \\
 &= -\sin^{n-1} x \cos x + (n-1) \int \sin^{n-2} x dx - (n-1) \int \sin^n x dx.
 \end{aligned}$$

We add $(n-1) \int \sin^n x dx$ to each side, and then divide by n to obtain

$$\begin{aligned}
 (1+n-1) \int \sin^n x dx &= -\sin^{n-1} x \cos x + (n-1) \int \sin^{n-2} x dx \\
 \int \sin^n x dx &= -\frac{\sin^{n-1} x \cos x}{n} + \frac{n-1}{n} \int \sin^{n-2} x dx.
 \end{aligned}$$

62. We use integration by parts with $u = \sin^{n-1} x$ and $dv = \sin x \cos^m x dx$. Then $du = (n-1) \sin^{n-2} x \cos x dx$ and $v = -\frac{\cos^{m+1} x}{m+1}$. We obtain

$$\begin{aligned}
 \int \sin^n x \cos^m x dx &= \sin^{n-1} x \left(-\frac{\cos^{m+1} x}{m+1} \right) - \int \left(-\frac{\cos^{m+1} x}{m+1} \right) (n-1) \sin^{n-2} x \cos x dx \\
 &= -\frac{\sin^{n-1} x \cos^{m+1} x}{m+1} + \frac{n-1}{m+1} \int \sin^{n-2} x \cos^{m+2} x dx \\
 &= -\frac{\sin^{n-1} x \cos^{m+1} x}{m+1} + \frac{n-1}{m+1} \int \sin^{n-2} x (1 - \sin^2 x) \cos^m x dx \\
 &= -\frac{\sin^{n-1} x \cos^{m+1} x}{m+1} + \frac{n-1}{m+1} \int \sin^{n-2} x \cos^m x dx \\
 &\quad - \frac{n-1}{m+1} \int \sin^n x \cos^m x dx.
 \end{aligned}$$

We add $\frac{n-1}{m+1} \int \sin^n x \cos^m x dx$ to each side, and then divide by $\frac{n+m}{m+1}$ to obtain

$$\begin{aligned}
 \left(1 + \frac{n-1}{m+1} \right) \int \sin^n x \cos^m x dx &= -\frac{\sin^{n-1} x \cos^{m+1} x}{m+1} + \frac{n-1}{m+1} \int \sin^{n-2} x \cos^m x dx \\
 \frac{n+m}{m+1} \int \sin^n x dx &= -\frac{\sin^{n-1} x \cos^{m+1} x}{m+1} + \frac{n-1}{m+1} \int \sin^{n-2} x \cos^m x dx \\
 \int \sin^n x dx &= -\frac{\sin^{n-1} x \cos^{m+1} x}{n+m} + \frac{n-1}{n+m} \int \sin^{n-2} x \cos^m x dx.
 \end{aligned}$$

63. (a) We use integration by parts with $u = x^2$ and $dv = e^{5x} dx$. Then $du = 2x dx$ and $v = \frac{1}{5} e^{5x}$. We obtain

$$\begin{aligned}
 \int x^2 e^{5x} dx &= x^2 \left(\frac{1}{5} e^{5x} \right) - \int \left(\frac{1}{5} e^{5x} \right) (2x) dx \\
 &= \frac{1}{5} x^2 e^{5x} - \frac{2}{5} \int x e^{5x} dx.
 \end{aligned}$$

We use integration by parts again with $u = x$ and $dv = e^{5x} dx$. Then $du = dx$ and $v = \frac{1}{5}e^{5x}$. We obtain

$$\begin{aligned}\int x^2 e^{5x} dx &= \frac{1}{5}x^2 e^{5x} - \frac{2}{5} \left[x \left(\frac{1}{5}e^{5x} \right) - \int \frac{1}{5}e^{5x} dx \right] \\ &= \frac{1}{5}x^2 e^{5x} - \frac{2}{25}x e^{5x} + \frac{2}{25} \int e^{5x} dx \\ &= \frac{1}{5}x^2 e^{5x} - \frac{2}{25}x e^{5x} + \frac{2}{25} \left(\frac{1}{5}e^{5x} \right) + C \\ &= \boxed{\frac{1}{5}x^2 e^{5x} - \frac{2}{25}x e^{5x} + \frac{2}{125}e^{5x} + C}.\end{aligned}$$

- (b) We use integration by parts with $u = x^n$ and $dv = e^{kx} dx$. Then $du = nx^{n-1} dx$ and $v = \frac{1}{k}e^{kx}$. We obtain

$$\begin{aligned}\int x^n e^{kx} dx &= x^n \left(\frac{1}{k}e^{kx} \right) - \int \left(\frac{1}{k}e^{kx} \right) (nx^{n-1}) dx \\ &= \boxed{\frac{1}{k}x^n e^{kx} - \frac{n}{k} \int x^{n-1} e^{kx} dx}.\end{aligned}$$

64. (a) If $\int x^3 e^x dx = p(x)e^x$, then $\frac{d}{dx}(p(x)e^x) = x^3 e^x$. So

$$\frac{d}{dx}(p(x)e^x) = p(x)e^x + p'(x)e^x = x^3 e^x.$$

Divide by e^x to obtain $p(x) + p'(x) = x^3$.

- (b) We use integration by parts with $u = x^3$ and $dv = e^x dx$. Then $du = 3x^2 dx$ and $v = e^x$. We obtain

$$\begin{aligned}\int x^3 e^x dx &= x^3 e^x - \int (e^x)(3x^2) dx \\ &= x^3 e^x - 3 \int x^2 e^x dx.\end{aligned}$$

We use integration by parts again with $u = x^2$ and $dv = e^x dx$. Then $du = 2x dx$ and $v = e^x$. We obtain

$$\begin{aligned}\int x^3 e^x dx &= x^3 e^x - 3 \left[x^2 e^x - \int (e^x)(2x) dx \right] \\ &= x^3 e^x - 3x^2 e^x + 6 \int x e^x dx.\end{aligned}$$

We use integration by parts again with $u = x$ and $dv = e^x dx$. Then $du = dx$ and $v = e^x$. We obtain

$$\begin{aligned}\int x^3 e^x dx &= x^3 e^x - 3x^2 e^x + 6 \left[x e^x - \int e^x dx \right] \\ &= x^3 e^x - 3x^2 e^x + 6x e^x - 6e^x + C \\ &= (x^3 - 3x^2 + 6x - 6)e^x + C.\end{aligned}$$

We have found the polynomial $\boxed{p(x) = x^3 - 3x^2 + 6x - 6}$.

65. (a) We use integration by parts with $u = \sin x$ and $dv = \cos x dx$. Then $du = \cos x dx$ and $v = \sin x$. We obtain

$$\begin{aligned}\int \sin x \cos x dx &= (\sin x)(\sin x) - \int (\sin x)(\cos x) dx \\ &= \sin^2 x - \int \sin x \cos x dx.\end{aligned}$$

We add $\int \sin x \cos x dx$ to each side, and then divide by 2 to obtain

$$\begin{aligned}2 \int \sin x \cos x dx &= \sin^2 x \\ \int \sin x \cos x dx &= \frac{1}{2} \sin^2 x + C_1.\end{aligned}$$

So we obtain $\boxed{f(x) = \frac{1}{2} \sin^2 x}$.

- (b) We use integration by parts with $u = \cos x$ and $dv = \sin x dx$. Then $du = -\sin x dx$ and $v = -\cos x$. We obtain

$$\begin{aligned}\int \sin x \cos x dx &= (\cos x)(-\cos x) - \int (-\cos x)(-\sin x) dx \\ &= -\cos^2 x - \int \sin x \cos x dx.\end{aligned}$$

We add $\int \sin x \cos x dx$ to each side, and then divide by 2 to obtain

$$\begin{aligned}2 \int \sin x \cos x dx &= -\cos^2 x \\ \int \sin x \cos x dx &= -\frac{1}{2} \cos^2 x + C_2.\end{aligned}$$

So we obtain $\boxed{g(x) = -\frac{1}{2} \cos^2 x}$.

- (c) From the identity $\sin(2x) = 2 \sin x \cos x$ we have $\sin x \cos x = \frac{1}{2} \sin(2x)$. So $\int \sin x \cos x dx = \frac{1}{2} \int \sin(2x) dx$. Let $u = 2x$, then $du = 2 dx$, so $dx = \frac{1}{2} du$. We substitute and obtain

$$\begin{aligned}\int \sin x \cos x dx &= \frac{1}{2} \int \sin(2x) dx \\ &= \frac{1}{2} \int \sin u \left(\frac{1}{2} du \right) \\ &= \frac{1}{4} \int \sin u du \\ &= \frac{1}{4} (-\cos u) + C_3 \\ &= -\frac{1}{4} \cos(2x) + C_3.\end{aligned}$$

So we obtain $\boxed{h(x) = -\frac{1}{4} \cos(2x)}$.

- (d) We have $f(x) + C_1 = g(x) + C_2$, so $\frac{1}{2} \sin^2 x + C_1 = -\frac{1}{2} \cos^2 x + C_2$. We obtain $C_2 = \frac{1}{2} \cos^2 x + \frac{1}{2} \sin^2 x + C_1 = \frac{1}{2} + C_1$, so $\boxed{C_2 = \frac{1}{2} + C_1}$.

- (e) We have $f(x) + C_1 = h(x) + C_3$, so $\frac{1}{2}\sin^2 x + C_1 = -\frac{1}{4}\cos(2x) + C_3$. We obtain $C_3 = \frac{1}{4}\cos(2x) + \frac{1}{2}\sin^2 x + C_1 = \frac{1}{4}(1 - 2\sin^2 x) + \frac{1}{2}\sin^2 x + C_1 = \frac{1}{4} + C_1$. So $C_3 = \frac{1}{4} + C_1$.

66. We use integration by parts with $u = \ln(x + \sqrt{x^2 + a^2})$ and $dv = dx$. Then

$$\begin{aligned} du &= \frac{1 + \frac{1}{2}(x^2 + a^2)^{-1/2}(2x)}{x + \sqrt{x^2 + a^2}} dx \\ &= \frac{1 + x(x^2 + a^2)^{-1/2}}{x + \sqrt{x^2 + a^2}} \frac{\sqrt{x^2 + a^2}}{\sqrt{x^2 + a^2}} dx \\ &= \frac{\sqrt{x^2 + a^2} + x}{(x + \sqrt{x^2 + a^2})\sqrt{x^2 + a^2}} dx \\ &= \frac{1}{\sqrt{x^2 + a^2}} dx \end{aligned}$$

and $v = x$. We obtain

$$\int \ln(x + \sqrt{x^2 + a^2}) dx = x \ln(x + \sqrt{x^2 + a^2}) - \int \frac{x}{\sqrt{x^2 + a^2}} dx.$$

Let $u = x^2 + a^2$, then $du = 2x dx$, so $x dx = \frac{du}{2}$. We substitute and obtain

$$\begin{aligned} \int \ln(x + \sqrt{x^2 + a^2}) dx &= x \ln(x + \sqrt{x^2 + a^2}) - \frac{1}{2} \int u^{-1/2} du \\ &= x \ln(x + \sqrt{x^2 + a^2}) - \frac{1}{2} (2u^{1/2}) + C \\ &= x \ln(x + \sqrt{x^2 + a^2}) - \sqrt{x^2 + a^2} + C. \end{aligned}$$

67. We use integration by parts with $u = \sin(bx)$ and $dv = e^{ax} dx$. Then $du = b \cos(bx) dx$ and $v = \frac{1}{a}e^{ax}$. We obtain

$$\begin{aligned} \int e^{ax} \sin(bx) dx &= (\sin(bx)) \left(\frac{1}{a}e^{ax} \right) - \int \left(\frac{1}{a}e^{ax} \right) (b \cos(bx)) dx \\ &= \frac{1}{a}e^{ax} \sin(bx) - \frac{b}{a} \int e^{ax} \cos(bx) dx \end{aligned}$$

We integrate by parts again with $u = \cos bx$ and $dv = e^{ax} dx$. Then $du = -b \sin bx dx$ and $v = \frac{1}{a}e^{ax}$. We obtain

$$\begin{aligned} \int e^{ax} \sin(bx) dx &= \frac{1}{a}e^{ax} \sin(bx) - \frac{b}{a} \left[(\cos(bx)) \left(\frac{1}{a}e^{ax} \right) - \int \left(\frac{1}{a}e^{ax} \right) (-b \sin(bx)) dx \right] \\ &= \frac{1}{a}e^{ax} \sin(bx) - \frac{b}{a^2}e^{ax} \cos(bx) - \frac{b^2}{a^2} \int e^{ax} \sin(bx) dx \end{aligned}$$

We add $\frac{b^2}{a^2} \int e^{ax} \sin(bx) dx$ from each side and divide by $\frac{a^2 + b^2}{a^2}$ to obtain

$$\begin{aligned} \left(1 + \frac{b^2}{a^2}\right) \int e^{ax} \sin(bx) dx &= \frac{1}{a}e^{ax} \sin(bx) - \frac{b}{a^2}e^{ax} \cos(bx) \\ \int e^{ax} \sin(bx) dx &= \frac{a}{a^2 + b^2}e^{ax} \sin(bx) - \frac{b}{a^2 + b^2}e^{ax} \cos(bx) + C \\ &= \frac{e^{ax} [a \sin(bx) - b \cos(bx)]}{a^2 + b^2} + C. \end{aligned}$$

68. We use integration by parts with $u = t$ and $dv = g'(t) dt$. Then $du = dt$ and $v = g(t)$. We obtain

$$\begin{aligned} F(x) &= \int_0^x t g'(t) dt = [t g(t)]_0^x - \int_0^x g(t) dt \\ &= x g(x) - 0 g(0) - \int_0^x g(t) dt \\ &= x g(x) - \int_0^x g(t) dt. \end{aligned}$$

69. (a) $\int_0^{\pi/2} \sin^6 x dx = \frac{(5)(3)(1)}{(6)(4)(2)} \left(\frac{\pi}{2}\right) = \boxed{\frac{5\pi}{32}}.$
 (b) $\int_0^{\pi/2} \sin^5 x dx = \frac{(4)(2)}{(5)(3)(1)} = \boxed{\frac{8}{15}}.$
 (c) $\int_0^{\pi/2} \cos^8 x dx = \int_0^{\pi/2} \sin^8 x dx = \frac{(7)(5)(3)(1)}{(8)(6)(4)(2)} \left(\frac{\pi}{2}\right) = \boxed{\frac{35\pi}{256}}.$
 (d) $\int_0^{\pi/2} \cos^6 x dx = \int_0^{\pi/2} \sin^6 x dx = \frac{(5)(3)(1)}{(6)(4)(2)} \left(\frac{\pi}{2}\right) = \boxed{\frac{5\pi}{32}}.$

Challenge Problems

70. Suppose first that $n = 2m + 1 > 1$ is odd, so that m is any positive integer. By Problem 61, we have

$$\begin{aligned} \int_0^{\pi/2} \sin^n x dx &= \left[-\frac{\sin^{n-1} x \cos x}{n} \right]_0^{\pi/2} + \frac{n-1}{n} \int_0^{\pi/2} \sin^{n-2} x dx \\ &= \left[-\frac{\sin^{n-1} \frac{\pi}{2} \cos \frac{\pi}{2}}{n} - \left(-\frac{\sin^{n-1} 0 \cos 0}{n} \right) \right] + \frac{n-1}{n} \int_0^{\pi/2} \sin^{n-2} x dx \\ &= \frac{n-1}{n} \int_0^{\pi/2} \sin^{n-2} x dx. \end{aligned}$$

We continue, and obtain

$$\begin{aligned} \int_0^{\pi/2} \sin^n x dx &= \frac{n-1}{n} \int_0^{\pi/2} \sin^{n-2} x dx \\ &= \frac{n-1}{n} \left(\frac{n-3}{n-2} \int_0^{\pi/2} \sin^{n-4} x dx \right) \\ &= \frac{n-1}{n} \frac{n-3}{n-2} \left(\frac{n-5}{n-4} \int_0^{\pi/2} \sin^{n-6} x dx \right) \\ &= \dots \\ &= \frac{n-1}{n} \frac{n-3}{n-2} \frac{n-5}{n-4} \dots \frac{2}{3} \int_0^{\pi/2} \sin x dx \\ &= \frac{n-1}{n} \frac{n-3}{n-2} \frac{n-5}{n-4} \dots \frac{2}{3} [-\cos x]_0^{\pi/2} \\ &= \frac{n-1}{n} \frac{n-3}{n-2} \frac{n-5}{n-4} \dots \frac{2}{3} (1) \\ &= \frac{(2m)(2m-2)\dots(2)}{(2m+1)(2m-1)\dots(3)(1)} \end{aligned}$$

So the formula holds. Now suppose that $n = 2m > 1$ is even, so that m is any positive integer. By the above, we have

$$\begin{aligned}
 \int_0^{\pi/2} \sin^n x \, dx &= \frac{n-1}{n} \int_0^{\pi/2} \sin^{n-2} x \, dx \\
 &= \frac{n-1}{n} \frac{n-3}{n-2} \frac{n-5}{n-4} \cdots \frac{3}{4} \int_0^{\pi/2} \sin^2 x \, dx \\
 &= \frac{n-1}{n} \frac{n-3}{n-2} \frac{n-5}{n-4} \cdots \frac{3}{4} \frac{1}{2} \int_0^{\pi/2} dx \\
 &= \frac{n-1}{n} \frac{n-3}{n-2} \frac{n-5}{n-4} \cdots \frac{3}{4} \frac{1}{2} \frac{\pi}{2} \\
 &= \frac{(2m-1)(2m-3)\cdots(3)(1)}{(2m)(2m-2)\cdots(4)(2)} \left(\frac{\pi}{2}\right),
 \end{aligned}$$

and the formula holds.

71. (a) We use integration by parts with $u = x^n$ and $dv = e^x dx$. Then $du = nx^{n-1} dx$ and $v = e^x$. We have

$$\int x^n e^x dx = x^n e^x - n \int x^{n-1} e^x dx$$

Repeating, we obtain for some constants c and k

$$\begin{aligned}
 \int x^n e^x dx &= x^n e^x - n \left(x^{n-1} e^x - (n-1) \int x^{n-2} e^x dx \right) \\
 &= (x^n - nx^{n-1}) e^x + n(n-1) \int x^{n-2} e^x dx \\
 &= \cdots \\
 &= (x^n - nx^{n-1} + \cdots + kx) e^x + c \int e^x dx \\
 &= (x^n - nx^{n-1} + \cdots + kx + c) e^x + C \\
 &= p(x) e^x + C.
 \end{aligned}$$

- (b) Since $\frac{d}{dx}(p(x)e^x) = x^n e^x$, we have $p(x)e^x + p'(x)e^x = x^n e^x$. Divide by e^x to obtain $p(x) + p'(x) = x^n$.

(c) We show $p(x) = \sum_{k=0}^n (-1)^k \frac{n!}{(n-k)!} x^{n-k}$ satisfies $p(x) + p'(x) = x^n$. We have

$$\begin{aligned}
 p(x) + p'(x) &= \sum_{k=0}^n (-1)^k \frac{n!}{(n-k)!} x^{n-k} + \frac{d}{dx} \left(\sum_{k=0}^n (-1)^k \frac{n!}{(n-k)!} x^{n-k} \right) \\
 &= x^n + \sum_{k=0}^{n-1} (-1)^k \frac{n!}{(n-k)!} x^{n-k} + \sum_{k=0}^{n-1} (-1)^k \frac{n!}{(n-k)!} (n-k) x^{n-k-1} \\
 &= x^n + \sum_{k=0}^{n-1} (-1)^k \frac{n!}{(n-k)!} x^{n-k} + \sum_{k=1}^n (-1)^{k-1} \frac{n!}{(n-(k-1))!} (n-(k-1)) x^{n-(k-1)-1} \\
 &= x^n + \sum_{k=0}^{n-1} (-1)^k \frac{n!}{(n-k)!} x^{n-k} + \sum_{k=1}^n (-1)^{k-1} \frac{n!}{(n-k+1)!} (n-k+1) x^{n-k} \\
 &= x^n + \sum_{k=0}^{n-1} (-1)^k \frac{n!}{(n-k)!} x^{n-k} + \sum_{k=1}^n (-1)^k (-1)^{-1} \frac{n!}{(n-k+1)(n-k)!} (n-k+1) x^{n-k} \\
 &= x^n + \sum_{k=0}^{n-1} (-1)^k \frac{n!}{(n-k)!} x^{n-k} - \sum_{k=1}^n (-1)^k \frac{n!}{(n-k)!} x^{n-k} \\
 &= x^n.
 \end{aligned}$$

72. Use integration by parts with $u = e^{x^2}$ and $dv = x^{2n} dx$. Then $du = 2xe^{x^2} dx$ and $v = \frac{1}{2n+1} x^{2n+1}$. We obtain

$$\begin{aligned}
 \int_0^1 x^{2n} e^{x^2} dx &= \left[\frac{1}{2n+1} x^{2n+1} e^{x^2} \right]_0^1 - \int_0^1 \left(\frac{1}{2n+1} x^{2n+1} \right) (2xe^{x^2}) dx \\
 &= e \left(\frac{1}{2n+1} \right) - \frac{2}{2n+1} \int_0^1 x^{2n+2} e^{x^2} dx.
 \end{aligned}$$

Starting with the $n = 0$ case, we repeat the above formula, and obtain

$$\begin{aligned}
 \int_0^1 e^{x^2} dx &= e \left(\frac{1}{1} \right) - \frac{2}{1} \int_0^1 x^2 e^{x^2} dx \\
 &= e(1) - \frac{2}{1} \left(e \left(\frac{1}{3} \right) - \frac{2}{3} \int_0^1 x^4 e^{x^2} dx \right) \\
 &= e \left(1 - \frac{2}{3} \right) + \frac{2^2}{3(1)} \int_0^1 x^6 e^{x^2} dx \\
 &= e \left(1 - \frac{2}{3} \right) + \frac{2^2}{3(1)} \left(e \left(\frac{1}{5} \right) - \frac{2}{5} \int_0^1 x^8 e^{x^2} dx \right) \\
 &= e \left(1 - \frac{2}{3} + \frac{2^2}{5(3)(1)} \right) + \frac{2^3}{5(3)(1)} \int_0^1 x^8 e^{x^2} dx \\
 &= \dots \\
 &= e \left[1 - \frac{2}{3} + \dots + \frac{(-1)^n 2^n}{(2n+1) \dots (3)(1)} \right] + \frac{(-1)^{n+1} 2^{n+1}}{(2n+1) \dots (3)(1)} \int_0^1 x^{2n+2} e^{x^2} dx.
 \end{aligned}$$

So the formula holds for all nonnegative integers n .

73. We use integration by parts with $u = f(x)$ and $dv = e^x dx$. Then $du = f'(x) dx$ and $v = e^x$. We have

$$\int f(x) e^x dx = f(x) e^x - \int f'(x) e^x dx$$

We continue, using $u = f'(x)$, $dv = e^x$ and obtain

$$\begin{aligned}
 \int f(x)e^x dx &= f(x)e^x - \left(f'(x)e^x - \int f''(x)e^x dx \right) \\
 &= (f(x) - f'(x))e^x + \int f''(x)e^x dx \\
 &= \dots \\
 &= \left(f(x) - f'(x) + \dots \pm f^{(n-1)}(x) \right) e^x \pm \int f^{(n)}(x)e^x dx
 \end{aligned}$$

Since $f(x)$ is a polynomial of degree n , $f^{(n)}(x)$ is a constant, k , and we have

$$\begin{aligned}
 \int f(x)e^x dx &= \left(f(x) - f'(x) + \dots \pm f^{(n-1)}(x) \right) e^x \pm \int k e^x dx \\
 &= \left(f(x) - f'(x) + \dots \pm f^{(n-1)}(x) \right) e^x \pm k e^x + C \\
 &= (f(x) - f'(x) + \dots \pm k) e^x + C.
 \end{aligned}$$

We now have $f(x) = g(x)e^x + C$, where $g(x) = f(x) - f'(x) + \dots \pm k$ is a polynomial of degree n .

74. (a) We use integration by parts with $u = f'(t)$ and $dv = dt$. Then $du = f''(t) dt$ and take $v = t - b$. We obtain

$$\begin{aligned}
 f(b) - f(a) &= \int_a^b f'(t) dt \\
 &= [(t - b)f'(t)]_a^b - \int_a^b f''(t)(t - b) dt \\
 &= (b - b)f'(b) - (a - b)f'(a) - \int_a^b f''(t)(t - b) dt \\
 &= f'(a)(b - a) - \int_a^b f''(t)(t - b) dt.
 \end{aligned}$$

- (b) We use integration by parts on $\int_a^b f''(t)(t - b) dt$ with $u = f''(t)$ and $dv = (t - b) dt$. Then $du = f'''(t) dt$ and $v = \frac{1}{2}(t - b)^2$. We obtain

$$\begin{aligned}
 f(b) - f(a) &= f'(a)(b - a) - \int_a^b f''(t)(t - b) dt \\
 &= f'(a)(b - a) - \left(\left[\frac{1}{2}(t - b)^2 f''(t) \right]_a^b - \int_a^b f'''(t) \frac{1}{2}(t - b)^2 dt \right) \\
 &= f'(a)(b - a) \\
 &\quad - \left(\left[\frac{1}{2}(b - b)^2 f''(b) - \frac{1}{2}(a - b)^2 f''(a) \right] - \int_a^b \frac{f'''(t)}{2}(t - b)^2 dt \right) \\
 &= f'(a)(b - a) + \frac{f''(a)}{2}(b - a)^2 + \int_a^b \frac{f'''(t)}{2}(t - b)^2 dt.
 \end{aligned}$$

75. We use integration by parts with $u = f(x)$ and $dv = dx$. Then $du = f'(x) dx$ and take $v = x$. We obtain

$$\begin{aligned}\int_a^b f(x) dx &= [xf(x)]_a^b - \int_a^b xf'(x) dx \\ &= bf(b) - af(a) - \int_a^b xf'(x) dx.\end{aligned}$$

Let $x = f^{-1}(y)$, then $f(x) = y$, so $f'(x) dx = dy$. The limits of integration become $y = f(a)$ and $y = f(b)$. We substitute and obtain

$$\int_a^b f(x) dx = bf(b) - af(a) - \int_{f(a)}^{f(b)} f^{-1}(y) dy,$$

so

$$\int_a^b f(x) dx + \int_{f(a)}^{f(b)} f^{-1}(y) dy = bf(b) - af(a).$$

76. (a) We use integration by parts with $u = \cosh x$ and $dv = e^x dx$. Then $du = \sinh x dx$ and take $v = e^x$. We obtain

$$\int e^x \cosh x dx = e^x \cosh x - \int e^x \sinh x dx.$$

We use integration by parts again with $u = \sinh x$ and $dv = e^x dx$. Then $du = \cosh x dx$ and take $v = e^x$. We obtain

$$\begin{aligned}\int e^x \cosh x dx &= e^x \cosh x - \left[e^x \sinh x - \int e^x \cosh x dx \right] \\ &= e^x \cosh x - e^x \sinh x + \int e^x \cosh x dx.\end{aligned}$$

The integrals cancel, and this will not allow us to determine the integral. Note that

$$\begin{aligned}e^x \cosh x - e^x \sinh x &= e^x (\cosh x - \sinh x) \\ &= e^x (e^{-x}) \\ &= 1.\end{aligned}$$

This is expected, as any two antiderivatives of $e^x \cosh x$, as denoted by $\int e^x \cosh x dx$ on each side of the equation

$$\int e^x \cosh x dx = e^x \cosh x - e^x \sinh x + \int e^x \cosh x dx,$$

must differ by a constant. So their difference, $e^x \cosh x - e^x \sinh x$, must be constant.

- (b) We rewrite $\cosh x = \frac{e^x + e^{-x}}{2}$, and obtain

$$\begin{aligned}\int e^x \cosh x dx &= \int e^x \left(\frac{e^x + e^{-x}}{2} \right) dx \\ &= \frac{1}{2} \int (e^{2x} + 1) dx \\ &= \frac{1}{2} \left(\frac{1}{2} e^{2x} + x \right) + C \\ &= \boxed{\frac{1}{4} e^{2x} + \frac{1}{2} x + C}.\end{aligned}$$

7.2: Integrals Containing Trigonometric Functions

Concepts and Vocabulary

1. True.

2. True.

Skill Building

3. Factor out $\cos x$ and use the identity $\cos^2 x = 1 - \sin^2 x$.

$$\begin{aligned}\int \cos^5 x \, dx &= \int \cos^4 x \cos x \, dx \\ &= \int (\cos^2 x)^2 \cos x \, dx \\ &= \int (1 - \sin^2 x)^2 \cos x \, dx.\end{aligned}$$

Let $u = \sin x$, then $du = \cos x \, dx$. We substitute and obtain

$$\begin{aligned}\int \cos^5 x \, dx &= \int (1 - u^2)^2 \, du \\ &= \int (u^4 - 2u^2 + 1) \, du \\ &= \frac{1}{5}u^5 - \frac{2}{3}u^3 + u + C \\ &= \boxed{\frac{1}{5}\sin^5 x - \frac{2}{3}\sin^3 x + \sin x + C}.\end{aligned}$$

4. Factor out $\sin x$ and use the identity $\sin^2 x = 1 - \cos^2 x$.

$$\begin{aligned}\int \sin^3 x \, dx &= \int \sin^2 x \sin x \, dx \\ &= \int (1 - \cos^2 x) \sin x \, dx.\end{aligned}$$

Let $u = \cos x$, then $du = -\sin x \, dx$, so $\sin x \, dx = -du$. We substitute and obtain

$$\begin{aligned}\int \sin^3 x \, dx &= \int (1 - u^2)(-du) \\ &= \int (u^2 - 1) \, du \\ &= \frac{1}{3}u^3 - u + C \\ &= \boxed{\frac{1}{3}\cos^3 x - \cos x + C}.\end{aligned}$$

5. Use the identity $\sin^2 x = \frac{1 - \cos(2x)}{2}$ and obtain

$$\begin{aligned}
 \int \sin^6 x \, dx &= \int (\sin^2 x)^3 \, dx \\
 &= \int \left(\frac{1 - \cos(2x)}{2} \right)^3 \, dx \\
 &= \frac{1}{8} \int (1 - 3 \cos(2x) + 3 \cos^2(2x) - \cos^3(2x)) \, dx \\
 &= \frac{1}{8} \int dx - \frac{3}{8} \int \cos(2x) \, dx + \frac{3}{8} \int \cos^2(2x) \, dx - \frac{1}{8} \int \cos^3(2x) \, dx \\
 &= \frac{1}{8} x - \frac{3}{16} \sin(2x) + \frac{3}{8} \int \cos^2(2x) \, dx - \frac{1}{8} \int \cos^3(2x) \, dx.
 \end{aligned}$$

We evaluate

$$\begin{aligned}
 \int \cos^2(2x) \, dx &= \int \frac{1 + \cos(4x)}{2} \, dx \\
 &= \frac{1}{2} \int (1 + \cos(4x)) \, dx \\
 &= \frac{x}{2} + \frac{\sin(4x)}{8} + C.
 \end{aligned}$$

And also

$$\begin{aligned}
 \int \cos^3(2x) \, dx &= \int \cos^2(2x) \cos(2x) \, dx \\
 &= \int (1 - \sin^2(2x)) \cos(2x) \, dx.
 \end{aligned}$$

Let $u = \sin(2x)$, then $du = 2 \cos(2x) \, dx$, so $\cos(2x) \, dx = \frac{du}{2}$. We substitute and obtain

$$\begin{aligned}
 \int \cos^3(2x) \, dx &= \int (1 - u^2) \frac{du}{2} \\
 &= \frac{1}{2} \left(u - \frac{u^3}{3} \right) + C \\
 &= \frac{\sin(2x)}{2} - \frac{\sin^3(2x)}{6} + C.
 \end{aligned}$$

We now obtain

$$\begin{aligned}
 \int \sin^6 x \, dx &= \frac{1}{8} x - \frac{3}{16} \sin(2x) + \frac{3}{8} \left(\frac{x}{2} + \frac{\sin(4x)}{8} \right) - \frac{1}{8} \left(\frac{\sin(2x)}{2} - \frac{\sin^3(2x)}{6} \right) + C \\
 &= \boxed{\frac{5}{16} x - \frac{1}{4} \sin(2x) + \frac{3}{64} \sin(4x) + \frac{1}{48} \sin^3(2x) + C}.
 \end{aligned}$$

6. Use the identity $\cos^2 x = \frac{1+\cos(2x)}{2}$ and obtain

$$\begin{aligned}
 \int \cos^4 x \, dx &= \int (\cos^2 x)^2 \, dx \\
 &= \int \left(\frac{1+\cos(2x)}{2} \right)^2 \, dx \\
 &= \frac{1}{4} \int (1 + 2\cos(2x) + \cos^2(2x)) \, dx \\
 &= \frac{1}{4} \int dx + \frac{1}{2} \int \cos(2x) \, dx + \frac{1}{4} \int \cos^2(2x) \, dx \\
 &= \frac{1}{4}x + \frac{1}{4}\sin(2x) + \frac{1}{4} \int \cos^2(2x) \, dx.
 \end{aligned}$$

We evaluate

$$\begin{aligned}
 \int \cos^2(2x) \, dx &= \int \frac{1+\cos(4x)}{2} \, dx \\
 &= \frac{1}{2} \int (1 + \cos(4x)) \, dx \\
 &= \frac{x}{2} + \frac{\sin(4x)}{8} + C.
 \end{aligned}$$

We now obtain

$$\begin{aligned}
 \int \cos^4 x \, dx &= \frac{1}{4}x + \frac{1}{4}\sin(2x) + \frac{1}{4} \left(\frac{x}{2} + \frac{\sin(4x)}{8} \right) + C \\
 &= \boxed{\frac{3}{8}x + \frac{1}{4}\sin(2x) + \frac{1}{32}\sin(4x) + C}.
 \end{aligned}$$

7. Use the identity $\sin^2(\pi x) = \frac{1-\cos(2\pi x)}{2}$ and obtain

$$\begin{aligned}
 \int \sin^2(\pi x) \, dx &= \int \frac{1-\cos(2\pi x)}{2} \, dx \\
 &= \frac{1}{2} \int (1 - \cos(2\pi x)) \, dx \\
 &= \frac{1}{2} \left(x - \frac{1}{2\pi} \sin(2\pi x) \right) + C \\
 &= \boxed{\frac{x}{2} - \frac{1}{4\pi} \sin(2\pi x) + C}.
 \end{aligned}$$

8. Use the identity $\cos^2(2x) = \frac{1+\cos(4x)}{2}$ and obtain

$$\begin{aligned}
 \int \cos^4(2x) \, dx &= \int (\cos^2(2x))^2 \, dx \\
 &= \int \left(\frac{1+\cos(4x)}{2} \right)^2 \, dx \\
 &= \frac{1}{4} \int (1 + 2\cos(4x) + \cos^2(4x)) \, dx \\
 &= \frac{1}{4} \int dx + \frac{1}{2} \int \cos(4x) \, dx + \frac{1}{4} \int \cos^2(4x) \, dx \\
 &= \frac{1}{4}x + \frac{1}{8}\sin(4x) + \frac{1}{4} \int \cos^2(4x) \, dx.
 \end{aligned}$$

We evaluate

$$\begin{aligned}\int \cos^2(4x) dx &= \int \frac{1 + \cos(8x)}{2} dx \\ &= \frac{1}{2} \int (1 + \cos(8x)) dx \\ &= \frac{x}{2} + \frac{\sin(8x)}{16} + C.\end{aligned}$$

We now obtain

$$\begin{aligned}\int \cos^4(2x) dx &= \frac{1}{4}x + \frac{1}{8}\sin(4x) + \frac{1}{4}\left(\frac{x}{2} + \frac{\sin(8x)}{16}\right) + C \\ &= \boxed{\frac{3}{8}x + \frac{1}{8}\sin(4x) + \frac{1}{64}\sin(8x) + C}.\end{aligned}$$

9. Factor out $\cos x$ and use the identity $\cos^2 x = 1 - \sin^2 x$.

$$\begin{aligned}\int_0^\pi \cos^5 x dx &= \int_0^\pi \cos^4 x \cos x dx \\ &= \int_0^\pi (\cos^2 x)^2 \cos x dx \\ &= \int_0^\pi (1 - \sin^2 x)^2 \cos x dx.\end{aligned}$$

Let $u = \sin x$, then $du = \cos x dx$. The lower limit of integration is $u = \sin 0 = 0$ and the upper limit of integration is $u = \sin \pi = 0$. We substitute and obtain

$$\int_0^\pi \cos^5 x dx = \int_0^0 (1 - u)^2 du = \boxed{0}.$$

10. Since $\sin^3 x$ is an odd function on a symmetric interval $[-\frac{\pi}{3}, \frac{\pi}{3}]$ about 0, we have

$$\int_{-\pi/3}^{\pi/3} \sin^3 x dx = \boxed{0}.$$

11. Factor out $\sin x$ and use the identity $\sin^2 x = 1 - \cos^2 x$.

$$\begin{aligned}\int \sin^3 x \cos^2 x dx &= \int \sin^2 x \cos^2 x \sin x dx \\ &= \int (1 - \cos^2 x) \cos^2 x \sin x dx.\end{aligned}$$

Let $u = \cos x$, then $du = -\sin x dx$, so $\sin x dx = -du$. We substitute and obtain

$$\begin{aligned}\int \sin^3 x \cos^2 x dx &= \int (1 - u^2)(u^2)(-du) \\ &= \int (u^4 - u^2) du \\ &= \frac{1}{5}u^5 - \frac{1}{3}u^3 + C \\ &= \boxed{\frac{1}{5}\cos^5 x - \frac{1}{3}\cos^3 x + C}.\end{aligned}$$

12. Factor out $\cos x$ and use the identity $\cos^2 x = 1 - \sin^2 x$.

$$\begin{aligned}\int \sin^4 x \cos^3 x \, dx &= \int \sin^4 x \cos^2 x \cos x \, dx \\ &= \int \sin^4 x (1 - \sin^2 x) \cos x \, dx.\end{aligned}$$

Let $u = \sin x$, then $du = \cos x \, dx$. We substitute and obtain

$$\begin{aligned}\int \sin^4 x \cos^3 x \, dx &= \int u^4 (1 - u^2) \, du \\ &= \int (u^4 - u^6) \, du \\ &= \frac{1}{5} u^5 - \frac{1}{7} u^7 + C \\ &= \boxed{\frac{1}{5} \sin^5 x - \frac{1}{7} \sin^7 x + C}.\end{aligned}$$

13. Use the identities $\cos^2 x = \frac{1+\cos(2x)}{2}$ and $\sin^2 x = \frac{1-\cos(2x)}{2}$ and obtain

$$\begin{aligned}\int \sin^2 x \cos^2 x \, dx &= \int \frac{1 - \cos(2x)}{2} \frac{1 + \cos(2x)}{2} \, dx \\ &= \frac{1}{4} \int (1 - \cos^2(2x)) \, dx \\ &= \frac{1}{4} x - \frac{1}{4} \int \cos^2(2x) \, dx.\end{aligned}$$

We evaluate

$$\begin{aligned}\int \cos^2(2x) \, dx &= \int \frac{1 + \cos(4x)}{2} \, dx \\ &= \frac{1}{2} \int (1 + \cos(4x)) \, dx \\ &= \frac{x}{2} + \frac{\sin(4x)}{8} + C.\end{aligned}$$

We now obtain

$$\begin{aligned}\int \sin^2 x \cos^2 x \, dx &= \frac{1}{4} x - \frac{1}{4} \left(\frac{x}{2} + \frac{\sin(4x)}{8} \right) + C \\ &= \boxed{\frac{1}{8} x - \frac{1}{32} \sin(4x) + C}.\end{aligned}$$

14. Use the identities $\cos^2 x = \frac{1+\cos(2x)}{2}$ and $\sin^2 x = \frac{1-\cos(2x)}{2}$ and obtain

$$\begin{aligned}\int \sin^4 x \cos^2 x \, dx &= \int (\sin^2 x)^2 \cos^2 x \, dx \\ &= \int \left(\frac{1 - \cos(2x)}{2} \right)^2 \frac{1 + \cos(2x)}{2} \, dx \\ &= \frac{1}{8} \int (1 - \cos(2x) - \cos^2(2x) + \cos^3(2x)) \, dx \\ &= \frac{x}{8} - \frac{\sin(2x)}{16} - \frac{1}{8} \int \cos^2(2x) \, dx + \frac{1}{8} \int \cos^3(2x) \, dx.\end{aligned}$$

We evaluate

$$\begin{aligned}\int \cos^2(2x) dx &= \int \frac{1 + \cos(4x)}{2} dx \\ &= \frac{1}{2} \int (1 + \cos(4x)) dx \\ &= \frac{x}{2} + \frac{\sin(4x)}{8} + C.\end{aligned}$$

And also

$$\begin{aligned}\int \cos^3(2x) dx &= \int \cos^2(2x) \cos(2x) dx \\ &= \int (1 - \sin^2(2x)) \cos(2x) dx.\end{aligned}$$

Let $u = \sin(2x)$, then $du = 2 \cos(2x) dx$, so $\cos(2x) dx = \frac{du}{2}$. We substitute and obtain

$$\begin{aligned}\int \cos^3(2x) dx &= \int (1 - u^2) \frac{du}{2} \\ &= \frac{1}{2} \left(u - \frac{u^3}{3} \right) + C \\ &= \frac{\sin(2x)}{2} - \frac{\sin^3(2x)}{6} + C.\end{aligned}$$

We now obtain

$$\begin{aligned}\int \sin^4 x \cos^2 x dx &= \frac{x}{8} - \frac{\sin(2x)}{16} - \frac{1}{8} \left(\frac{x}{2} + \frac{\sin(4x)}{8} \right) + \frac{1}{8} \left(\frac{\sin(2x)}{2} - \frac{\sin^3(2x)}{6} \right) + C \\ &= \boxed{\frac{1}{16}x - \frac{1}{64}\sin(4x) - \frac{1}{48}\sin^3(2x) + C}.\end{aligned}$$

15. Let $u = \cos x$, then $du = -\sin x dx$, so $\sin x dx = -du$. We substitute and obtain

$$\begin{aligned}\int \sin x \cos^{1/3} x dx &= \int u^{1/3}(-du) \\ &= -\int u^{1/3} du \\ &= -\frac{3}{4}u^{4/3} + C \\ &= \boxed{-\frac{3}{4}\cos^{4/3} x + C}.\end{aligned}$$

16. Factor out $\cos x$ and use the identity $\cos^2 x = 1 - \sin^2 x$.

$$\begin{aligned}\int \cos^3 x \sin^{1/2} x dx &= \int \cos^2 x \sin^{1/2} x \cos x dx \\ &= \int (1 - \sin^2 x) \sin^{1/2} x \cos x dx.\end{aligned}$$

Let $u = \sin x$, then $du = \cos x \, dx$. We substitute and obtain

$$\begin{aligned}\int \cos^3 x \sin^{1/2} x \, dx &= \int (1 - u^2) u^{1/2} \, du \\ &= \int (u^{1/2} - u^{5/2}) \, du \\ &= \frac{2}{3} u^{3/2} - \frac{2}{7} u^{7/2} + C \\ &= \boxed{\frac{2}{3} \sin^{3/2} x - \frac{2}{7} \sin^{7/2} x + C}.\end{aligned}$$

17. Factor out $\cos\left(\frac{x}{2}\right)$ and use the identity $\cos^2\left(\frac{x}{2}\right) = 1 - \sin^2\left(\frac{x}{2}\right)$.

$$\begin{aligned}\int \sin^2\left(\frac{x}{2}\right) \cos^3\left(\frac{x}{2}\right) \, dx &= \int \cos^2\left(\frac{x}{2}\right) \sin^2\left(\frac{x}{2}\right) \cos\left(\frac{x}{2}\right) \, dx \\ &= \int \left(1 - \sin^2\left(\frac{x}{2}\right)\right) \sin^2\left(\frac{x}{2}\right) \cos\left(\frac{x}{2}\right) \, dx.\end{aligned}$$

Let $u = \sin\left(\frac{x}{2}\right)$, then $du = \frac{1}{2} \cos\left(\frac{x}{2}\right) \, dx$, so $\cos\left(\frac{x}{2}\right) \, dx = 2 \, du$. We substitute and obtain

$$\begin{aligned}\int \sin^2\left(\frac{x}{2}\right) \cos^3\left(\frac{x}{2}\right) \, dx &= \int (1 - u^2)(u^2)(2 \, du) \\ &= 2 \int (u^2 - u^4) \, du \\ &= 2\left(\frac{1}{3} u^3 - \frac{1}{5} u^5\right) + C \\ &= \boxed{\frac{2}{3} \sin^3\left(\frac{x}{2}\right) - \frac{2}{5} \sin^5\left(\frac{x}{2}\right) + C}.\end{aligned}$$

18. Factor out $\cos(4x)$ and use the identity $\cos^2(4x) = 1 - \sin^2(4x)$.

$$\begin{aligned}\int \sin^3(4x) \cos^3(4x) \, dx &= \int \cos^2(4x) \sin^3(4x) \cos(4x) \, dx \\ &= \int (1 - \sin^2(4x)) \sin^3(4x) \cos(4x) \, dx.\end{aligned}$$

Let $u = \sin(4x)$, then $du = 4 \cos(4x) \, dx$, so $\cos(4x) \, dx = \frac{du}{4}$. We substitute and obtain

$$\begin{aligned}\int \sin^3(4x) \cos^3(4x) \, dx &= \int (1 - u^2)(u^3) \frac{du}{4} \\ &= \frac{1}{4} \int (u^3 - u^5) \, du \\ &= \frac{1}{4} \left(\frac{1}{4} u^4 - \frac{1}{6} u^6\right) + C \\ &= \boxed{\frac{1}{16} \sin^4(4x) - \frac{1}{24} \sin^6(4x) + C}.\end{aligned}$$

19. Let $u = \tan x$, then $du = \sec^2 x \, dx$. We substitute and obtain

$$\begin{aligned}\int \tan^3 x \sec^2 x \, dx &= \int u^3 \, du \\ &= \frac{1}{4} u^4 + C \\ &= \boxed{\frac{1}{4} \tan^4 x + C}.\end{aligned}$$

20. Factor out $\sec x \tan x$. Then let $u = \sec x$, so $du = \sec x \tan x \, dx$. We substitute and obtain

$$\begin{aligned}\int \tan x \sec^5 x \, dx &= \int \sec^4 x \sec x \tan x \, dx \\ &= \int u^4 \, du \\ &= \frac{1}{5} u^5 + C \\ &= \boxed{\frac{1}{5} \sec^5 x + C}.\end{aligned}$$

21. Let $u = \tan x$, then $du = \sec^2 x \, dx$. We substitute and obtain

$$\begin{aligned}\int \tan^2 x \sec^2 x \, dx &= \int u^2 \, du \\ &= \frac{1}{3} u^3 + C \\ &= \boxed{\frac{1}{3} \tan^3 x + C}.\end{aligned}$$

22. Let $u = \tan x$, then $du = \sec^2 x \, dx$. We substitute and obtain

$$\begin{aligned}\int \tan^5 x \sec^2 x \, dx &= \int u^5 \, du \\ &= \frac{1}{6} u^6 + C \\ &= \boxed{\frac{1}{6} \tan^6 x + C}.\end{aligned}$$

23. We first use the identity $\tan^2 x = \sec^2 x - 1$.

$$\begin{aligned}\int \tan^2 x \sec^3 x \, dx &= \int (\sec^2 x - 1) \sec^3 x \, dx \\ &= \int \sec^5 x \, dx - \int \sec^3 x \, dx.\end{aligned}$$

We use integration by parts for $\int \sec^5 x \, dx$ with $u = \sec^3 x$ and $dv = \sec^2 x \, dx$. Then $du = 3 \sec^3 x \tan x \, dx$ and $v = \tan x$. We obtain

$$\begin{aligned}\int \sec^5 x \, dx &= \sec^3 x \tan x - 3 \int (\sec^3 x \tan x) \tan x \, dx \\ &= \sec^3 x \tan x - 3 \int \sec^3 x \tan^2 x \, dx \\ &= \sec^3 x \tan x - 3 \int \sec^3 x (\sec^2 x - 1) \, dx \\ &= \sec^3 x \tan x - 3 \int \sec^5 x \, dx + 3 \int \sec^3 x \, dx.\end{aligned}$$

We add $3 \int \sec^5 x \, dx$ to both sides, and divide by 4 and obtain

$$\begin{aligned}4 \int \sec^5 x \, dx &= \sec^3 x \tan x + 3 \int \sec^3 x \, dx \\ \int \sec^5 x \, dx &= \frac{1}{4} \sec^3 x \tan x + \frac{3}{4} \int \sec^3 x \, dx.\end{aligned}$$

We now have

$$\begin{aligned}
 \int \tan^2 x \sec^3 x \, dx &= \int \sec^5 x \, dx - \int \sec^3 x \, dx \\
 &= \frac{1}{4} \sec^3 x \tan x + \frac{3}{4} \int \sec^3 x \, dx - \int \sec^3 x \, dx \\
 &= \frac{1}{4} \sec^3 x \tan x - \frac{1}{4} \int \sec^3 x \, dx.
 \end{aligned}$$

From Example 7 we have $\int \sec^3 x \, dx = \frac{1}{2} [\sec x \tan x + \ln |\sec x + \tan x|] + C$, so

$$\begin{aligned}
 \int \tan^2 x \sec^3 x \, dx &= \frac{1}{4} \sec^3 x \tan x - \frac{1}{4} \left(\frac{1}{2} [\sec x \tan x + \ln |\sec x + \tan x|] \right) + C \\
 &= \boxed{\frac{1}{4} \sec^3 x \tan x - \frac{1}{8} \sec x \tan x - \frac{1}{8} \ln |\sec x + \tan x| + C}.
 \end{aligned}$$

24. We first use the identity $\tan^2 x = \sec^2 x - 1$.

$$\begin{aligned}
 \int \tan^4 x \sec x \, dx &= \int (\tan^2 x)^2 \sec x \, dx \\
 &= \int (\sec^2 x - 1)^2 \sec x \, dx \\
 &= \int (\sec^4 x - 2 \sec^2 x + 1) \sec x \, dx \\
 &= \int \sec^5 x \, dx - 2 \int \sec^3 x \, dx + \int \sec x \, dx \\
 &= \int \sec^5 x \, dx - 2 \int \sec^3 x \, dx + \ln |\sec x + \tan x|
 \end{aligned}$$

We use integration by parts for $\int \sec^5 x \, dx$ with $u = \sec^3 x$ and $dv = \sec^2 x \, dx$. Then $du = 3 \sec^3 x \tan x \, dx$ and $v = \tan x$. We obtain

$$\begin{aligned}
 \int \sec^5 x \, dx &= \sec^3 x \tan x - 3 \int (\sec^3 x \tan x) \tan x \, dx \\
 &= \sec^3 x \tan x - 3 \int \sec^3 x \tan^2 x \, dx \\
 &= \sec^3 x \tan x - 3 \int \sec^3 x (\sec^2 x - 1) \, dx \\
 &= \sec^3 x \tan x - 3 \int \sec^5 x \, dx + 3 \int \sec^3 x \, dx.
 \end{aligned}$$

We add $3 \int \sec^5 x \, dx$ to both sides, and divide by 4 and obtain

$$\begin{aligned}
 4 \int \sec^5 x \, dx &= \sec^3 x \tan x + 3 \int \sec^3 x \, dx \\
 \int \sec^5 x \, dx &= \frac{1}{4} \sec^3 x \tan x + \frac{3}{4} \int \sec^3 x \, dx.
 \end{aligned}$$

We now have

$$\begin{aligned}
 \int \tan^4 x \sec x \, dx &= \frac{1}{4} \sec^3 x \tan x + \frac{3}{4} \int \sec^3 x \, dx - 2 \int \sec^3 x \, dx + \ln |\sec x + \tan x| \\
 &= \frac{1}{4} \sec^3 x \tan x - \frac{5}{4} \int \sec^3 x \, dx + \ln |\sec x + \tan x|.
 \end{aligned}$$

From Example 7 we have $\int \sec^3 x \, dx = \frac{1}{2} [\sec x \tan x + \ln |\sec x + \tan x|] + C$, so

$$\begin{aligned} \int \tan^4 x \sec x \, dx &= \frac{1}{4} \sec^3 x \tan x - \frac{5}{4} \left(\frac{1}{2} [\sec x \tan x + \ln |\sec x + \tan x|] \right) \\ &\quad + \ln |\sec x + \tan x| + C \\ &= \boxed{\frac{1}{4} \sec^3 x \tan x - \frac{5}{8} \sec x \tan x + \frac{3}{8} \ln |\sec x + \tan x| + C}. \end{aligned}$$

25. Factor out $\csc x \cot x$, and use the identity $\cot^2 x = \csc^2 x - 1$.

$$\begin{aligned} \int \cot^3 x \csc x \, dx &= \int \cot^2 x \csc x \cot x \, dx \\ &= \int (\csc^2 x - 1) \csc x \cot x \, dx. \end{aligned}$$

Let $u = \csc x$, then $du = -\csc x \cot x \, dx$, so $\csc x \cot x \, dx = -du$. We substitute and obtain

$$\begin{aligned} \int \cot^3 x \csc x \, dx &= \int (\csc^2 x - 1) \csc x \cot x \, dx \\ &= \int (u^2 - 1)(-du) \\ &= \int (1 - u^2) \, du \\ &= u - \frac{1}{3} u^3 + C \\ &= \boxed{\csc x - \frac{1}{3} \csc^3 x + C}. \end{aligned}$$

26. Let $u = \cot x$, then $du = -\csc^2 x \, dx$, so $\csc^2 x \, dx = -du$. We substitute and obtain

$$\begin{aligned} \int \cot^3 x \csc^2 x \, dx &= \int u^3 (-du) \\ &= -\int u^3 \, du \\ &= -\frac{1}{4} u^4 + C \\ &= \boxed{-\frac{1}{4} \cot^4 x + C}. \end{aligned}$$

27. We use the identity $\sin A \cos B = \frac{1}{2} (\sin(A+B) + \sin(A-B))$ to obtain

$$\begin{aligned} \int \sin(3x) \cos x \, dx &= \frac{1}{2} \int (\sin(4x) + \sin(2x)) \, dx \\ &= \frac{1}{2} \left(-\frac{1}{4} \cos(4x) - \frac{1}{2} \cos(2x) \right) + C \\ &= \boxed{-\frac{1}{8} \cos(4x) - \frac{1}{4} \cos(2x) + C}. \end{aligned}$$

28. We use the identity $\sin A \cos B = \frac{1}{2}(\sin(A+B) + \sin(A-B))$ to obtain

$$\begin{aligned}\int \sin x \cos(3x) dx &= \frac{1}{2} \int (\sin(4x) + \sin(-2x)) dx \\ &= \frac{1}{2} \int (\sin(4x) - \sin(2x)) dx \\ &= \frac{1}{2} \left(-\frac{1}{4} \cos(4x) - \left(-\frac{1}{2} \cos(2x) \right) \right) + C \\ &= \boxed{-\frac{1}{8} \cos(4x) + \frac{1}{4} \cos(2x) + C}.\end{aligned}$$

29. We use the identity $\cos A \cos B = \frac{1}{2}(\cos(A+B) + \cos(A-B))$ to obtain

$$\begin{aligned}\int \cos x \cos(3x) dx &= \frac{1}{2} \int (\cos(4x) + \cos(-2x)) dx \\ &= \frac{1}{2} \int (\cos(4x) + \cos(2x)) dx \\ &= \frac{1}{2} \left(\frac{1}{4} \sin(4x) + \frac{1}{2} \sin(2x) \right) + C \\ &= \boxed{\frac{1}{8} \sin(4x) + \frac{1}{4} \sin(2x) + C}.\end{aligned}$$

30. We use the identity $\cos A \cos B = \frac{1}{2}(\cos(A+B) + \cos(A-B))$ to obtain

$$\begin{aligned}\int \cos(2x) \cos x dx &= \frac{1}{2} \int (\cos(3x) + \cos(x)) dx \\ &= \frac{1}{2} \left(\frac{1}{3} \sin(3x) + \sin x \right) + C \\ &= \boxed{\frac{1}{6} \sin(3x) + \frac{1}{2} \sin x + C}.\end{aligned}$$

31. We use the identity $\sin A \sin B = \frac{1}{2}(\cos(A-B) - \cos(A+B))$ to obtain

$$\begin{aligned}\int \sin(2x) \sin(4x) dx &= \frac{1}{2} \int (\cos(-2x) - \cos(6x)) dx \\ &= \frac{1}{2} \int (\cos(2x) - \cos(6x)) dx \\ &= \frac{1}{2} \left(\frac{1}{2} \sin(2x) - \frac{1}{6} \sin(6x) \right) + C \\ &= \boxed{\frac{1}{4} \sin(2x) - \frac{1}{12} \sin(6x) + C}.\end{aligned}$$

32. We use the identity $\sin A \sin B = \frac{1}{2}(\cos(A-B) - \cos(A+B))$ to obtain

$$\begin{aligned}\int \sin(3x) \sin(x) dx &= \frac{1}{2} \int (\cos(3x-x) - \cos(3x+x)) dx \\ &= \frac{1}{2} \int (\cos(2x) - \cos(4x)) dx \\ &= \frac{1}{2} \left(\frac{1}{2} \sin(2x) - \frac{1}{4} \sin(4x) \right) + C \\ &= \boxed{\frac{1}{4} \sin(2x) - \frac{1}{8} \sin(4x) + C}.\end{aligned}$$

33. We use the identity $\sin A \sin B = \frac{1}{2}(\cos(A - B) - \cos(A + B))$ to obtain

$$\begin{aligned}
 \int_0^{\pi/2} \sin(2x) \sin x \, dx &= \frac{1}{2} \int_0^{\pi/2} (\cos(x) - \cos(3x)) \, dx \\
 &= \frac{1}{2} \left[\sin x - \frac{1}{3} \sin(3x) \right]_0^{\pi/2} \\
 &= \frac{1}{2} \left[\left(\sin \frac{\pi}{2} - \frac{1}{3} \sin \left(\frac{3\pi}{2} \right) \right) - \left(\sin 0 - \frac{1}{3} \sin(3(0)) \right) \right] \\
 &= \frac{1}{2} \left(\frac{4}{3} - 0 \right) \\
 &= \boxed{\frac{2}{3}}.
 \end{aligned}$$

34. We use the identity $\cos A \cos B = \frac{1}{2}(\cos(A + B) + \cos(A - B))$ to obtain

$$\begin{aligned}
 \int_0^{\pi} \cos x \cos(4x) \, dx &= \frac{1}{2} \int_0^{\pi} (\cos(5x) + \cos(-3x)) \, dx \\
 &= \frac{1}{2} \int_0^{\pi} (\cos(5x) + \cos(3x)) \, dx \\
 &= \frac{1}{2} \left[\frac{1}{5} \sin(5x) + \frac{1}{3} \sin(3x) \right]_0^{\pi} \\
 &= \frac{1}{2} \left[\frac{1}{5} \sin(5\pi) + \frac{1}{3} \sin(3\pi) - \left(\frac{1}{5} \sin(5(0)) + \frac{1}{3} \sin(3(0)) \right) \right] \\
 &= \boxed{0}.
 \end{aligned}$$

35. Let $u = \sin x$, then $du = \cos x \, dx$. We substitute and obtain

$$\begin{aligned}
 \int \sin^2 x \cos x \, dx &= \int u^2 \, du \\
 &= \frac{1}{3} u^3 + C \\
 &= \boxed{\frac{1}{3} \sin^3 x + C}.
 \end{aligned}$$

36. Let $u = \sin x$, then $du = \cos x \, dx$. We substitute and obtain

$$\begin{aligned}
 \int \sin^3 x \cos x \, dx &= \int u^3 \, du \\
 &= \frac{1}{4} u^4 + C \\
 &= \boxed{\frac{1}{4} \sin^4 x + C}.
 \end{aligned}$$

37. We rewrite the integral, and obtain

$$\begin{aligned}
 \int \frac{\sin x}{\cos^2 x} \, dx &= \int \frac{1}{\cos x} \frac{\sin x}{\cos x} \, dx \\
 &= \int \sec x \tan x \, dx \\
 &= \boxed{\sec x + C}.
 \end{aligned}$$

38. We rewrite the integral, and obtain

$$\begin{aligned}\int \frac{\cos x}{\sin^4 x} dx &= \int \frac{1}{\sin^3 x} \frac{\cos x}{\sin x} dx \\ &= \int \csc^3 x \cot x dx \\ &= \int \csc^2 x (\csc x \cot x) dx.\end{aligned}$$

Let $u = \csc x$, then $du = -\csc x \cot x dx$, so $\csc x \cot x dx = -du$. We substitute and obtain

$$\begin{aligned}\int \frac{\cos x}{\sin^4 x} dx &= \int u^2 (-du) \\ &= -\int u^2 du \\ &= -\frac{1}{3}u^3 + C \\ &= \boxed{-\frac{1}{3}\csc^3 x + C}.\end{aligned}$$

39. Factor out $\cos(3x)$ and use the identity $\cos^2(3x) = 1 - \sin^2(3x)$.

$$\begin{aligned}\int \cos^3(3x) dx &= \int \cos^2(3x) \cos(3x) dx \\ &= \int (1 - \sin^2(3x)) \cos(3x) dx.\end{aligned}$$

Let $u = \sin(3x)$, then $du = 3 \cos(3x) dx$, so $\cos(3x) dx = \frac{du}{3}$. We substitute and obtain

$$\begin{aligned}\int \cos^3(3x) dx &= \int (1 - u^2) \frac{du}{3} \\ &= \frac{1}{3} \int (1 - u^2) du \\ &= \frac{1}{3} \left(u - \frac{1}{3}u^3 \right) + C \\ &= \boxed{\frac{1}{3} \sin(3x) - \frac{1}{9} \sin^3(3x) + C}.\end{aligned}$$

40. Factor out $\sin(3x)$ and use the identity $\sin^2(3x) = 1 - \cos^2(3x)$.

$$\begin{aligned}\int \sin^5(3x) dx &= \int \sin^4(3x) \sin(3x) dx \\ &= \int (\sin^2(3x))^2 \sin(3x) dx \\ &= \int (1 - \cos^2(3x))^2 \sin(3x) dx.\end{aligned}$$

Let $u = \cos(3x)$, then $du = -3 \sin(3x) dx$, so $\sin x dx = -\frac{du}{3}$. We substitute and obtain

$$\begin{aligned}\int \sin^5(3x) dx &= \int (1 - u^2)^2 \left(-\frac{du}{3}\right) \\&= -\frac{1}{3} \int (u^4 - 2u^2 + 1) du \\&= -\frac{1}{3} \left(\frac{1}{5}u^5 - \frac{2}{3}u^3 + u\right) + C \\&= \boxed{-\frac{1}{15} \cos^5(3x) + \frac{2}{9} \cos^3(3x) - \frac{1}{3} \cos(3x) + C}.\end{aligned}$$

41. Factor out $\sin x$ and use the identity $\sin^2 x = 1 - \cos^2 x$.

$$\begin{aligned}\int_0^\pi \sin^3 x \cos^5 x dx &= \int_0^\pi \sin^2 x \cos^5 x \sin x dx \\&= \int_0^\pi (1 - \cos^2 x) \cos^5 x \sin x dx.\end{aligned}$$

Let $u = \cos x$, then $du = -\sin x dx$, so $\sin x dx = -du$. The lower limit of integration is $u = \cos 0 = 1$, and the upper limit of integration is $u = \cos \pi = -1$. We substitute and obtain

$$\begin{aligned}\int_0^\pi \sin^3 x \cos^5 x dx &= \int_1^{-1} (1 - u^2) u^5 (-du) \\&= \int_{-1}^1 (u^5 - u^7) du \\&= \boxed{0},\end{aligned}$$

since we are integrating an odd function on a symmetric interval about 0.

42. Factor out $\sin x$ and use the identity $\sin^2 x = 1 - \cos^2 x$.

$$\begin{aligned}\int_0^{\pi/2} \sin^3 x \cos^3 x dx &= \int_0^{\pi/2} \sin^2 x \cos^3 x \sin x dx \\&= \int_0^{\pi/2} (1 - \cos^2 x) \cos^3 x \sin x dx.\end{aligned}$$

Let $u = \cos x$, then $du = -\sin x dx$, so $\sin x dx = -du$. The lower limit of integration is $u = \cos 0 = 1$, and the upper limit of integration is $u = \cos \frac{\pi}{2} = 0$. We substitute and obtain

$$\begin{aligned}\int_0^{\pi/2} \sin^3 x \cos^3 x dx &= \int_1^0 (1 - u^2) u^3 (-du) \\&= \int_0^1 (u^3 - u^5) du \\&= \left[\frac{1}{4}u^4 - \frac{1}{6}u^6\right]_0^1 \\&= \left(\frac{1}{4}1^4 - \frac{1}{6}1^6\right) - \left(\frac{1}{4}0^4 - \frac{1}{6}0^6\right) \\&= \boxed{\frac{1}{12}}.\end{aligned}$$

43. Rewrite the integral, factor out $\sin x$, and use the identity $\sin^2 x = 1 - \cos^2 x$ to obtain

$$\begin{aligned}\int \tan^3 x \, dx &= \int \frac{\sin^3 x}{\cos^3 x} \, dx \\ &= \int \frac{\sin^2 x}{\cos^3 x} \sin x \, dx \\ &= \int \frac{1 - \cos^2 x}{\cos^3 x} \sin x \, dx.\end{aligned}$$

Let $u = \cos x$, then $du = -\sin x \, dx$, so $\sin x \, dx = -du$. We substitute and obtain

$$\begin{aligned}\int \tan^3 x \, dx &= \int \frac{1 - u^2}{u^3} (-du) \\ &= \int \left(\frac{1}{u} - u^{-3} \right) du \\ &= \ln |u| - \frac{u^{-2}}{-2} + C \\ &= \boxed{\ln |\cos x| + \frac{1}{2} \sec^2 x + C}.\end{aligned}$$

44. Rewrite the integral, factor out $\cos x$, and use the identity $\cos^2 x = 1 - \sin^2 x$ to obtain

$$\begin{aligned}\int \cot^5 x \, dx &= \int \frac{\cos^5 x}{\sin^5 x} \, dx \\ &= \int \frac{\cos^4 x}{\sin^5 x} \cos x \, dx \\ &= \int \frac{(\cos^2 x)^2}{\sin^5 x} \cos x \, dx \\ &= \int \frac{(1 - \sin^2 x)^2}{\sin^5 x} \cos x \, dx\end{aligned}$$

Let $u = \sin x$, then $du = \cos x \, dx$. We substitute and obtain

$$\begin{aligned}\int \cot^5 x \, dx &= \int \frac{(1 - u^2)^2}{u^5} \, du \\ &= \int \frac{1 - 2u^2 + u^4}{u^5} \, du \\ &= \int \left(u^{-5} - 2u^{-3} + \frac{1}{u} \right) du \\ &= -\frac{1}{4}u^{-4} + u^{-2} + \ln |u| + C \\ &= \boxed{-\frac{1}{4} \csc^4 x + \csc^2 x + \ln |\sin x| + C}.\end{aligned}$$

45. Factor out $\sec^2 x$ and use the identity $\sec^2 x = 1 + \tan^2 x$.

$$\begin{aligned}\int \frac{\sec^6 x}{\tan^3 x} \, dx &= \int \frac{\sec^4 x}{\tan^3 x} \sec^2 x \, dx \\ &= \int \frac{(\sec^2 x)^2}{\tan^3 x} \sec^2 x \, dx \\ &= \int \frac{(1 + \tan^2 x)^2}{\tan^3 x} \sec^2 x \, dx.\end{aligned}$$

Let $u = \tan x$, then $du = \sec^2 x \, dx$. We substitute and obtain

$$\begin{aligned}
 \int \frac{\sec^6 x}{\tan^3 x} \, dx &= \int \frac{(1+u^2)^2}{u^3} \, du \\
 &= \int \frac{1+2u^2+u^4}{u^3} \, du \\
 &= \int \left(u^{-3} + \frac{2}{u} + u \right) \, du \\
 &= \frac{u^{-2}}{-2} + 2 \ln |u| + \frac{1}{2} u^2 + C \\
 &= \boxed{-\frac{1}{2} \cot^2 x + 2 \ln |\tan x| + \frac{1}{2} \tan^2 x + C}.
 \end{aligned}$$

46. Let $u = \tan x$, then $du = \sec^2 x \, dx$. We substitute and obtain

$$\begin{aligned}
 \int \tan^{1/2} x \sec^2 x \, dx &= \int u^{1/2} \, du \\
 &= \frac{2}{3} u^{3/2} + C \\
 &= \boxed{\frac{2}{3} \tan^{3/2} x + C}.
 \end{aligned}$$

47. Let $u = \cot x$, then $du = -\csc^2 x \, dx$, so $\csc^2 x \, dx = -du$. We substitute and obtain

$$\begin{aligned}
 \int \csc^2 x \cot^5 x \, dx &= \int u^5 (-du) \\
 &= -\int u^5 \, du \\
 &= -\frac{1}{6} u^6 + C \\
 &= \boxed{-\frac{1}{6} \cot^6 x + C}.
 \end{aligned}$$

48. Let $u = \cot x$, then $du = -\csc^2 x \, dx$, so $\csc^2 x \, dx = -du$. We substitute and obtain

$$\begin{aligned}
 \int \cot x \csc^2 x \, dx &= \int u (-du) \\
 &= -\int u \, du \\
 &= -\frac{1}{2} u^2 + C \\
 &= \boxed{-\frac{1}{2} \cot^2 x + C}.
 \end{aligned}$$

49. Factor out $\csc(2x) \cot(2x)$ to obtain

$$\int \cot(2x) \csc^4(2x) \, dx = \int \csc^3(2x) \csc(2x) \cot(2x) \, dx.$$

Let $u = \csc(2x)$, then $du = -2 \csc(2x) \cot(2x) \, dx$, so $\csc x \cot x \, dx = -\frac{du}{2}$. We substitute

and obtain

$$\begin{aligned}
 \int \cot(2x) \csc^4(2x) dx &= \int u^3 \left(-\frac{du}{2} \right) \\
 &= -\frac{1}{2} \int u^3 du \\
 &= -\frac{1}{2} \left(\frac{1}{4} u^4 \right) + C \\
 &= \boxed{-\frac{1}{8} \csc^4(2x) + C}.
 \end{aligned}$$

50. We first use the identity $\cot^2(2x) = \csc^2(2x) - 1$.

$$\begin{aligned}
 \int \cot^2(2x) \csc^3(2x) dx &= \int (\csc^2(2x) - 1) \csc^3(2x) dx \\
 &= \int \csc^5(2x) dx - \int \csc^3(2x) dx.
 \end{aligned}$$

We use integration by parts for $\int \csc^5(2x) dx$ with $u = \csc^3(2x)$ and $dv = \csc^2(2x) dx$. Then $du = -6 \csc^3(2x) \cot(2x) dx$ and $v = -\frac{1}{2} \cot(2x)$. We obtain

$$\begin{aligned}
 \int \csc^5(2x) dx &= -\frac{1}{2} \csc^3(2x) \cot(2x) - 3 \int (\csc^3(2x) \cot(2x)) \cot(2x) dx \\
 &= -\frac{1}{2} \csc^3(2x) \cot(2x) - 3 \int \csc^3(2x) \cot^2(2x) dx \\
 &= -\frac{1}{2} \csc^3(2x) \cot(2x) - 3 \int \csc^3(2x) (\csc^2(2x) - 1) dx \\
 &= -\frac{1}{2} \csc^3(2x) \cot(2x) - 3 \int \csc^5(2x) dx + 3 \int \csc^3(2x) dx.
 \end{aligned}$$

We add $3 \int \csc^5(2x) dx$ to both sides, and divide by 4 and obtain

$$\begin{aligned}
 4 \int \csc^5(2x) dx &= -\frac{1}{2} \csc^3(2x) \cot(2x) + 3 \int \csc^3(2x) dx \\
 \int \csc^5(2x) dx &= -\frac{1}{8} \csc^3(2x) \cot(2x) + \frac{3}{4} \int \csc^3(2x) dx.
 \end{aligned}$$

We now have

$$\begin{aligned}
 \int \cot^2(2x) \csc^3(2x) dx &= \int \csc^5(2x) dx - \int \csc^3(2x) dx \\
 &= -\frac{1}{8} \csc^3(2x) \cot(2x) + \frac{3}{4} \int \csc^3(2x) dx - \int \csc^3(2x) dx \\
 &= -\frac{1}{8} \csc^3(2x) \cot(2x) - \frac{1}{4} \int \csc^3(2x) dx.
 \end{aligned}$$

We use integration by parts for $\int \csc^3(2x) dx$ with $u = \csc(2x)$ and $dv = \csc^2(2x) dx$.

Then $du = -2 \csc(2x) \cot(2x) dx$ and $v = -\frac{1}{2} \cot(2x)$. We obtain

$$\begin{aligned}
 \int \csc^3(2x) dx &= -\frac{1}{2} \csc(2x) \cot(2x) - \int (\csc(2x) \cot(2x)) \cot(2x) dx \\
 &= -\frac{1}{2} \csc(2x) \cot(2x) - \int \csc(2x) \cot^2(2x) dx \\
 &= -\frac{1}{2} \csc(2x) \cot(2x) - \int \csc(2x) (\csc^2(2x) - 1) dx \\
 &= -\frac{1}{2} \csc(2x) \cot(2x) - \int \csc^3(2x) dx + \int \csc(2x) dx \\
 &= -\frac{1}{2} \csc(2x) \cot(2x) - \int \csc^3(2x) dx - \frac{1}{2} \ln |\csc(2x) + \cot(2x)|.
 \end{aligned}$$

We add $\int \csc^3(2x) dx$ to both sides, and divide by 2 and obtain

$$\begin{aligned}
 2 \int \csc^3(2x) dx &= -\frac{1}{2} \csc(2x) \cot(2x) - \frac{1}{2} \ln |\csc(2x) + \cot(2x)| \\
 \int \csc^3(2x) dx &= -\frac{1}{4} \csc(2x) \cot(2x) - \frac{1}{4} \ln |\csc(2x) + \cot(2x)| + C.
 \end{aligned}$$

We now have

$$\begin{aligned}
 \int \cot^2(2x) \csc^3(2x) dx &= \frac{-\csc^3(2x) \cot(2x)}{8} - \frac{1}{4} \left(\frac{-\csc(2x) \cot(2x)}{4} - \frac{\ln |\csc(2x) + \cot(2x)|}{4} \right) + C \\
 &= \boxed{-\frac{\csc^3(2x) \cot(2x)}{8} + \frac{\csc(2x) \cot(2x)}{16} + \frac{\ln |\csc(2x) + \cot(2x)|}{16} + C}.
 \end{aligned}$$

51. We rewrite the integral using the identity $\tan^2 x = \sec^2 x - 1$.

$$\begin{aligned}
 \int_0^{\pi/4} \tan^4 x \sec^3 x dx &= \int_0^{\pi/4} (\tan^2 x)^2 \sec^3 x dx \\
 &= \int_0^{\pi/4} (\sec^2 x - 1)^2 \sec^3 x dx \\
 &= \int_0^{\pi/4} (\sec^4 x - 2 \sec^2 x + 1) \sec^3 x dx \\
 &= \int_0^{\pi/4} \sec^7 x dx - 2 \int_0^{\pi/4} \sec^5 x dx + \int_0^{\pi/4} \sec^3 x dx.
 \end{aligned}$$

From Example 7 we have $\int \sec^3 x dx = \frac{1}{2} [\sec x \tan x + \ln |\sec x + \tan x|] + C$, so

$$\begin{aligned}
 \int_0^{\pi/4} \sec^3 x dx &= \frac{1}{2} [\sec x \tan x + \ln |\sec x + \tan x|]_0^{\pi/4} \\
 &= \frac{1}{2} \left[\sec \frac{\pi}{4} \tan \frac{\pi}{4} + \ln \left| \sec \frac{\pi}{4} + \tan \frac{\pi}{4} \right| - (\sec 0 \tan 0 + \ln |\sec 0 + \tan 0|) \right] \\
 &= \frac{1}{2} \ln (\sqrt{2} + 1) + \frac{\sqrt{2}}{2}.
 \end{aligned}$$

We use integration by parts for $\int_0^{\pi/4} \sec^5 x dx$ with $u = \sec^3 x$ and $dv = \sec^2 x dx$. Then

$du = 3 \sec^3 x \tan x \, dx$ and $v = \tan x$. We obtain

$$\begin{aligned}
\int_0^{\pi/4} \sec^5 x \, dx &= [\sec^3 x \tan x]_0^{\pi/4} - 3 \int_0^{\pi/4} (\sec^3 x \tan x) \tan x \, dx \\
&= \sec^3 \frac{\pi}{4} \tan \frac{\pi}{4} - (\sec^3 0 \tan 0) - 3 \int_0^{\pi/4} \sec^3 x \tan^2 x \, dx \\
&= 2\sqrt{2} - 3 \int_0^{\pi/4} \sec^3 x (\sec^2 x - 1) \, dx \\
&= 2\sqrt{2} - 3 \left(\int_0^{\pi/4} \sec^5 x \, dx - \int_0^{\pi/4} \sec^3 x \, dx \right) \\
&= 2\sqrt{2} - 3 \int_0^{\pi/4} \sec^5 x \, dx + 3 \left(\frac{1}{2} \ln(\sqrt{2} + 1) + \frac{\sqrt{2}}{2} \right) \\
&= \frac{3}{2} \ln(\sqrt{2} + 1) + \frac{7}{2} \sqrt{2} - 3 \int_0^{\pi/4} \sec^5 x \, dx.
\end{aligned}$$

We add $3 \int_0^{\pi/4} \sec^5 x \, dx$ to each side and divide by 4 to obtain

$$\begin{aligned}
4 \int_0^{\pi/4} \sec^5 x \, dx &= \frac{3}{2} \ln(\sqrt{2} + 1) + \frac{7}{2} \sqrt{2} \\
\int_0^{\pi/4} \sec^5 x \, dx &= \frac{3}{8} \ln(\sqrt{2} + 1) + \frac{7}{8} \sqrt{2}.
\end{aligned}$$

We use integration by parts for $\int_0^{\pi/4} \sec^7 x \, dx$ with $u = \sec^5 x$ and $dv = \sec^2 x \, dx$. Then $du = 5 \sec^5 x \tan x \, dx$ and $v = \tan x$. We obtain

$$\begin{aligned}
\int_0^{\pi/4} \sec^7 x \, dx &= [\sec^5 x \tan x]_0^{\pi/4} - 5 \int_0^{\pi/4} (\sec^5 x \tan x) \tan x \, dx \\
&= \sec^5 \frac{\pi}{4} \tan \frac{\pi}{4} - (\sec^5 0 \tan 0) - 5 \int_0^{\pi/4} \sec^5 x \tan^2 x \, dx \\
&= 4\sqrt{2} - 5 \int_0^{\pi/4} \sec^5 x (\sec^2 x - 1) \, dx \\
&= 4\sqrt{2} - 5 \left(\int_0^{\pi/4} \sec^7 x \, dx - \int_0^{\pi/4} \sec^5 x \, dx \right) \\
&= 4\sqrt{2} - 5 \int_0^{\pi/4} \sec^7 x \, dx + 5 \left(\frac{3}{8} \ln(\sqrt{2} + 1) + \frac{7}{8} \sqrt{2} \right) \\
&= \frac{15}{8} \ln(\sqrt{2} + 1) + \frac{67}{8} \sqrt{2} - 5 \int_0^{\pi/4} \sec^7 x \, dx.
\end{aligned}$$

We add $5 \int_0^{\pi/4} \sec^7 x \, dx$ to each side and divide by 6 to obtain

$$\begin{aligned}
6 \int_0^{\pi/4} \sec^7 x \, dx &= \frac{15}{8} \ln(\sqrt{2} + 1) + \frac{67}{8} \sqrt{2} \\
\int_0^{\pi/4} \sec^7 x \, dx &= \frac{5}{16} \ln(\sqrt{2} + 1) + \frac{67}{48} \sqrt{2}.
\end{aligned}$$

We now obtain

$$\begin{aligned}
 \int_0^{\pi/4} \tan^4 x \sec^3 x \, dx &= \int_0^{\pi/4} \sec^7 x \, dx - 2 \int_0^{\pi/4} \sec^5 x \, dx + \int_0^{\pi/4} \sec^3 x \, dx \\
 &= \left(\frac{5}{16} \ln(\sqrt{2} + 1) + \frac{67}{48} \sqrt{2} \right) - 2 \left(\frac{3}{8} \ln(\sqrt{2} + 1) + \frac{7}{8} \sqrt{2} \right) \\
 &\quad + \left(\frac{1}{2} \ln(\sqrt{2} + 1) + \frac{\sqrt{2}}{2} \right) \\
 &= \boxed{\frac{7}{48} \sqrt{2} + \frac{1}{16} \ln(\sqrt{2} + 1)}.
 \end{aligned}$$

52. We rewrite the integral using the identity $\tan^2 x = \sec^2 x - 1$.

$$\begin{aligned}
 \int_0^{\pi/4} \tan^2 x \sec x \, dx &= \int_0^{\pi/4} (\sec^2 x - 1) \sec x \, dx \\
 &= \int_0^{\pi/4} \sec^3 x \, dx - \int_0^{\pi/4} \sec x \, dx \\
 &= \int_0^{\pi/4} \sec^3 x \, dx - [\ln |\sec x + \tan x|]_0^{\pi/4} \\
 &= \int_0^{\pi/4} \sec^3 x \, dx - \left[\ln \left| \sec \frac{\pi}{4} + \tan \frac{\pi}{4} \right| - \ln |\sec 0 + \tan 0| \right] \\
 &= \int_0^{\pi/4} \sec^3 x \, dx - \ln(\sqrt{2} + 1)
 \end{aligned}$$

From Example 7 we have $\int \sec^3 x \, dx = \frac{1}{2} [\sec x \tan x + \ln |\sec x + \tan x|] + C$, so

$$\begin{aligned}
 \int_0^{\pi/4} \sec^3 x \, dx &= \frac{1}{2} [\sec x \tan x + \ln |\sec x + \tan x|]_0^{\pi/4} \\
 &= \frac{1}{2} \left[\sec \frac{\pi}{4} \tan \frac{\pi}{4} + \ln \left| \sec \frac{\pi}{4} + \tan \frac{\pi}{4} \right| - (\sec 0 \tan 0 + \ln |\sec 0 + \tan 0|) \right] \\
 &= \frac{1}{2} \ln(\sqrt{2} + 1) + \frac{\sqrt{2}}{2}.
 \end{aligned}$$

We now obtain

$$\begin{aligned}
 \int_0^{\pi/4} \tan^2 x \sec x \, dx &= \int_0^{\pi/4} \sec^3 x \, dx - \ln(\sqrt{2} + 1) \\
 &= \left(\frac{1}{2} \ln(\sqrt{2} + 1) + \frac{\sqrt{2}}{2} \right) - \ln(\sqrt{2} + 1) \\
 &= \frac{1}{2} \sqrt{2} - \frac{1}{2} \ln(\sqrt{2} + 1).
 \end{aligned}$$

53. We use the identity $\sin A \cos B = \frac{1}{2} (\sin(A + B) + \sin(A - B))$ to obtain

$$\begin{aligned}
 \int \sin\left(\frac{x}{2}\right) \cos\left(\frac{3x}{2}\right) \, dx &= \frac{1}{2} \int (\sin(2x) + \sin(-x)) \, dx \\
 &= \frac{1}{2} \int (\sin(2x) - \sin(x)) \, dx \\
 &= \frac{1}{2} \left(-\frac{1}{2} \cos(2x) - (-\cos(x)) \right) + C \\
 &= \boxed{-\frac{1}{4} \cos(2x) + \frac{1}{2} \cos(x) + C}.
 \end{aligned}$$

54. We use the identity $\sin A \cos B = \frac{1}{2}(\sin(A+B) + \sin(A-B))$ to obtain

$$\begin{aligned}
 \int \cos(-x) \sin(4x) dx &= \int \sin(4x) \cos(-x) dx = \\
 &= \frac{1}{2} \int (\sin(3x) + \sin(5x)) dx \\
 &= \frac{1}{2} \left(-\frac{1}{3} \cos(3x) - \frac{1}{5} \cos(5x) \right) + C \\
 &= \boxed{-\frac{1}{6} \cos(3x) - \frac{1}{10} \cos(5x) + C}.
 \end{aligned}$$

55. We use the identity $\sin A \sin B = \frac{1}{2}(\cos(A-B) - \cos(A+B))$ to obtain

$$\begin{aligned}
 \int \sin\left(\frac{x}{2}\right) \sin\left(\frac{3x}{2}\right) dx &= \frac{1}{2} \int (\cos(-x) - \cos(2x)) dx \\
 &= \frac{1}{2} \int (\cos(x) - \cos(2x)) dx \\
 &= \frac{1}{2} \left(\sin x - \frac{1}{2} \sin(2x) \right) + C \\
 &= \boxed{\frac{1}{2} \sin x - \frac{1}{4} \sin(2x) + C}.
 \end{aligned}$$

56. We use the identity $\cos A \cos B = \frac{1}{2}(\cos(A+B) + \cos(A-B))$ to obtain

$$\begin{aligned}
 \int \cos(\pi x) \cos(3\pi x) dx &= \frac{1}{2} \int (\cos(4\pi x) + \cos(-2\pi x)) dx \\
 &= \frac{1}{2} \int (\cos(4\pi x) + \cos(2\pi x)) dx \\
 &= \frac{1}{2} \left(\frac{1}{4\pi} \sin(4\pi x) + \frac{1}{2\pi} \sin(2\pi x) \right) + C \\
 &= \boxed{\frac{1}{8\pi} \sin(4\pi x) + \frac{1}{4\pi} \sin(2\pi x) + C}.
 \end{aligned}$$

57. The volume is given by the integral $\int_0^\pi \pi(\sin x)^2 dx$. We write $\sin^2 x = \frac{1-\cos(2x)}{2}$ and obtain

$$\begin{aligned}
 \int_0^\pi \pi(\sin x)^2 dx &= \int_0^\pi \pi \left(\frac{1-\cos(2x)}{2} \right) dx \\
 &= \frac{\pi}{2} \int_0^\pi (1-\cos(2x)) dx \\
 &= \frac{\pi}{2} \left[x - \frac{1}{2} \sin(2x) \right]_0^\pi \\
 &= \frac{\pi}{2} \left[\pi - \frac{1}{2} \sin(2\pi) - \left(0 - \frac{1}{2} \sin(2(0)) \right) \right] \\
 &= \boxed{\frac{1}{2} \pi^2}.
 \end{aligned}$$

58. The volume is given by the integral $\int_0^{\pi/4} \pi [(\cos x)^2 - (\sin x)^2] dx$. We write $\cos^2 x - \sin^2 x = \cos(2x)$ and obtain

$$\begin{aligned} \int_0^{\pi/4} \pi [(\cos x)^2 - (\sin x)^2] dx &= \int_0^{\pi/4} \pi \cos(2x) dx \\ &= \pi \int_0^{\pi/4} \cos(2x) dx \\ &= \pi \left[\frac{1}{2} \sin(2x) \right]_0^{\pi/4} \\ &= \pi \left[\frac{1}{2} \sin\left(2\left(\frac{\pi}{4}\right)\right) - \frac{1}{2} \sin(2(0)) \right] \\ &= \boxed{\frac{1}{2}\pi}. \end{aligned}$$

59. (a) The average value is given by $\frac{1}{\pi-0} \int_0^{\pi} \sin x \cos^4 x dx$. Let $u = \cos x$, then $du = -\sin x dx$, so $\sin x dx = -du$. The lower limit of integration is $u = \cos 0 = 1$, and the upper limit of integration is $u = \cos \pi = -1$. We substitute and obtain

$$\begin{aligned} \frac{1}{\pi-0} \int_0^{\pi} \sin x \cos^4 x dx &= \frac{1}{\pi} \int_1^{-1} u^4 (-du) \\ &= \frac{1}{\pi} \int_{-1}^1 u^4 du \\ &= \frac{2}{\pi} \int_0^1 u^4 du \end{aligned}$$

using that we have an even function on an interval symmetric about 0. So

$$\begin{aligned} \frac{1}{\pi-0} \int_0^{\pi} \sin x \cos^4 x dx &= \frac{2}{\pi} \left[\frac{1}{5} u^5 \right]_0^1 \\ &= \frac{2}{\pi} \left[\frac{1}{5} 1^5 - \frac{1}{5} 0^5 \right] \\ &= \boxed{\frac{2}{5\pi}}. \end{aligned}$$

- (b) The area under the graph of the function f is the same as the area of the rectangle with height $\frac{2}{5\pi} \approx 0.1273$ and width $\pi - 0 = \pi$.

(c)

60. The velocity is given by

$$\begin{aligned} v(t) &= v(0) + \int_0^t a(w) dw \\ &= 5 + \int_0^t \cos^2 w \sin w dw. \end{aligned}$$

Let $u = \cos w$, then $du = -\sin w dw$, so $\sin w dw = -du$. The lower limit of integration is $u = \cos 0 = 1$, and the upper limit of integration is $u = \cos t$. We substitute and obtain

$$\begin{aligned} v(t) &= 5 + \int_1^{\cos t} u^2 (-du) \\ &= 5 - \int_1^{\cos t} u^2 du \\ &= 5 - \left[\frac{1}{3} u^3 \right]_1^{\cos t} \\ &= 5 - \left[\frac{1}{3} \cos^3 t - \frac{1}{3} \cos^3 0 \right] \\ &= \frac{16}{3} - \frac{1}{3} \cos^3 t. \end{aligned}$$

The distance is given by

$$\begin{aligned} s(t) &= s(0) + \int_0^t v(w) dw \\ &= 0 + \int_0^t \left(\frac{16}{3} - \frac{1}{3} \cos^3 w \right) dw \\ &= \frac{16}{3}t - \frac{1}{3} \int_0^t \cos^3 w dw. \end{aligned}$$

We factor out $\cos w$ and use the identity $\cos^2 w = 1 - \sin^2 w$. Let $u = \sin w$, then $du = \cos w dw$, the lower limit of integration is $u = \sin 0 = 0$, and the upper limit of integration is $u = \sin t$. We substitute and obtain

$$\begin{aligned} s(t) &= \frac{16}{3}t - \frac{1}{3} \int_0^t \cos^2 w \cos w dw \\ &= \frac{16}{3}t - \frac{1}{3} \int_0^t (1 - \sin^2 w) \cos w dw \\ &= \frac{16}{3}t - \frac{1}{3} \int_0^{\sin t} (1 - u^2) du \\ &= \frac{16}{3}t - \frac{1}{3} \left[u - \frac{1}{3} u^3 \right]_0^{\sin t} \\ &= \frac{16}{3}t - \frac{1}{3} \left[\sin t - \frac{1}{3} \sin^3 t - \left(\sin 0 - \frac{1}{3} \sin^3 0 \right) \right] \\ &= \boxed{\frac{16}{3}t - \frac{1}{3} \sin t + \frac{1}{9} \sin^3 t}. \end{aligned}$$

61. (a) Since $\sec x > 2 \sin x$ on the interval $[0, \frac{\pi}{4}]$, the area A is determined by

$$\begin{aligned}
 A &= \int_0^{\pi/4} (\sec x - 2 \sin x) dx \\
 &= [\ln |\sec x + \tan x| - (-2 \cos x)]_0^{\pi/4} \\
 &= \left(\ln \left| \sec \frac{\pi}{4} + \tan \frac{\pi}{4} \right| + 2 \cos \frac{\pi}{4} \right) - (\ln |\sec 0 + \tan 0| + 2 \cos 0) \\
 &= \boxed{\ln(\sqrt{2} + 1) + \sqrt{2} - 2}.
 \end{aligned}$$

- (b) The volume is given by the integral $\int_0^{\pi/4} \pi [(\sec x)^2 - (2 \sin x)^2] dx$. We use the identity $\sin^2 x = \frac{1 - \cos(2x)}{2}$ and obtain

$$\begin{aligned}
 \int_0^{\pi/4} \pi [(\sec x)^2 - (2 \sin x)^2] dx &= \int_0^{\pi/4} \pi \left[\sec^2 x - 4 \frac{1 - \cos(2x)}{2} \right] dx \\
 &= \pi \int_0^{\pi/4} [\sec^2 x - 2 + 2 \cos(2x)] dx \\
 &= \pi [\tan x - 2x + \sin(2x)]_0^{\pi/4} \\
 &= \pi \left[\tan \frac{\pi}{4} - 2\left(\frac{\pi}{4}\right) + \sin\left(2\left(\frac{\pi}{4}\right)\right) \right. \\
 &\quad \left. - [\tan 0 - 2(0) + \sin(2 \cdot 0)] \right] \\
 &= \boxed{\frac{4\pi - \pi^2}{2}}.
 \end{aligned}$$

62. (a)

- (b) Using a Computer Algebra System, we find

$$\int_0^{\pi} \sin^5 x dx \approx 1.067, \quad \int_0^{\pi} \sin^{10} x dx \approx 0.773, \quad \int_0^{\pi} \sin^{20} x dx \approx 0.554, \quad \text{and} \quad \int_0^{\pi} \sin^{50} x dx \approx 0.353.$$

- (c) The shape of the graph appears to contract towards $x = \frac{\pi}{2}$, becoming very narrow, as $n \rightarrow \infty$.
- (d) We continue to evaluate, and obtain $\int_0^{\pi} \sin^{100} x dx \approx 0.250$, $\int_0^{\pi} \sin^{1000} x dx \approx 0.0792$, and $\int_0^{\pi} \sin^{10000} x dx \approx 0.0251$. We surmise that

$$\lim_{n \rightarrow \infty} \int_0^{\pi} \sin^n x dx = \boxed{0}.$$

63. (a) Use the identity $\sin^2 x = \frac{1 - \cos(2x)}{2}$ and obtain

$$\begin{aligned}
 \int \sin^4 x \, dx &= \int (\sin^2 x)^2 \, dx \\
 &= \int \left(\frac{1 - \cos(2x)}{2} \right)^2 \, dx \\
 &= \frac{1}{4} \int (1 - 2\cos(2x) + \cos^2(2x)) \, dx \\
 &= \frac{1}{4} \int dx - \frac{1}{2} \int \cos(2x) \, dx + \frac{1}{4} \int \cos^2(2x) \, dx \\
 &= \frac{1}{4}x - \frac{1}{4}\sin(2x) + \frac{1}{4} \int \cos^2(2x) \, dx.
 \end{aligned}$$

We evaluate

$$\begin{aligned}
 \int \cos^2(2x) \, dx &= \int \frac{1 + \cos(4x)}{2} \, dx \\
 &= \frac{1}{2} \int (1 + \cos(4x)) \, dx \\
 &= \frac{x}{2} + \frac{\sin(4x)}{8} + C.
 \end{aligned}$$

We now obtain

$$\begin{aligned}
 \int \cos^4 x \, dx &= \frac{1}{4}x - \frac{1}{4}\sin(2x) + \frac{1}{4} \left(\frac{x}{2} + \frac{\sin(4x)}{8} \right) + C \\
 &= \boxed{\frac{3}{8}x - \frac{1}{4}\sin(2x) + \frac{1}{32}\sin(4x) + C}.
 \end{aligned}$$

(b) Use $\int \sin^n x \, dx = -\frac{\sin^{n-1} x \cos x}{n} + \frac{n-1}{n} \int \sin^{n-2} x \, dx$ with $n = 4$ to obtain

$$\begin{aligned}
 \int \sin^4 x \, dx &= -\frac{\sin^3 x \cos x}{4} + \frac{4-1}{4} \int \sin^{4-2} x \, dx \\
 &= -\frac{\sin^3 x \cos x}{4} + \frac{3}{4} \int \sin^2 x \, dx.
 \end{aligned}$$

And again with $n = 2$,

$$\begin{aligned}
 \int \sin^4 x \, dx &= -\frac{\sin^3 x \cos x}{4} + \frac{3}{4} \left(-\frac{\sin^{2-1} x \cos x}{2} + \frac{2-1}{2} \int \sin^{2-2} x \, dx \right) \\
 &= -\frac{\sin^3 x \cos x}{4} - \frac{3 \sin x \cos x}{8} + \frac{3}{8} \int dx \\
 &= \boxed{-\frac{\sin^3 x \cos x}{4} - \frac{3 \sin x \cos x}{8} + \frac{3}{8}x + C}.
 \end{aligned}$$

(c) We have

$$\begin{aligned}
 \frac{3}{8}x - \frac{1}{4}\sin(2x) + \frac{1}{32}\sin(4x) &= \frac{3}{8}x - \frac{1}{4}(2\sin x \cos x) + \frac{1}{32}(2\sin(2x) \cos(2x)) \\
 &= \frac{3}{8}x - \frac{1}{2}\sin x \cos x + \frac{1}{16}(2\sin x \cos x)(1 - 2\sin^2 x) \\
 &= \frac{3}{8}x - \frac{1}{2}\sin x \cos x + \frac{1}{8}\sin x \cos x - \frac{1}{4}\sin^3 x \cos x \\
 &= -\frac{\sin^3 x \cos x}{4} - \frac{3 \sin x \cos x}{8} + \frac{3}{8}x.
 \end{aligned}$$

So the two antiderivatives are equal.

(d) Using a Computer Algebra System, we obtain

$$\int \sin^4 x \, dx = \frac{3}{8}x - \frac{1}{4}\sin(2x) + \frac{1}{32}\sin(4x) + C,$$

which agrees with the result obtained in part (a).

64. (a) Let $u = \sin x$, then $du = \cos x \, dx$. We substitute and obtain

$$\begin{aligned} \int \sin x \cos x \, dx &= \int u \, du \\ &= \frac{1}{2}u^2 + C_1 \\ &= \frac{1}{2}\sin^2 x + C_1. \end{aligned}$$

So a function is $\boxed{f(x) = \frac{1}{2}\sin^2 x}$.

(b) Let $u = \cos x$, then $du = -\sin x \, dx$, so $\sin x \, dx = -du$. We substitute and obtain

$$\begin{aligned} \int \sin x \cos x \, dx &= \int u(-du) \\ &= -\frac{1}{2}u^2 + C_2 \\ &= -\frac{1}{2}\cos^2 x + C_2. \end{aligned}$$

So a function is $\boxed{g(x) = -\frac{1}{2}\cos^2 x}$.

(c) From the identity $\sin(2x) = 2\sin x \cos x$ we have $\sin x \cos x = \frac{1}{2}\sin(2x)$. So $\int \sin x \cos x \, dx = \frac{1}{2}\int \sin(2x) \, dx$. Let $u = 2x$, then $du = 2 \, dx$, so $dx = \frac{1}{2} \, du$. We substitute and obtain

$$\begin{aligned} \int \sin x \cos x \, dx &= \frac{1}{2} \int \sin(2x) \, dx \\ &= \frac{1}{2} \int \sin u \left(\frac{1}{2} \, du\right) \\ &= \frac{1}{4} \int \sin u \, du \\ &= \frac{1}{4}(-\cos u) + C_3 \\ &= -\frac{1}{4}\cos(2x) + C_3. \end{aligned}$$

So the function is $\boxed{h(x) = -\frac{1}{4}\cos(2x)}$.

(d) We have $f(x) - g(x) = \frac{1}{2}\sin^2 x - (-\frac{1}{2}\cos^2 x) = \frac{1}{2}(\sin^2 x + \cos^2 x) = \frac{1}{2}$.

(e) We have $f(x) - h(x) = \frac{1}{2}\sin^2 x - (-\frac{1}{4}\cos(2x)) = \frac{1}{2}\sin^2 x + \frac{1}{4}(2\cos^2 x - 1) = \frac{1}{2}(\sin^2 x + \cos^2 x) - \frac{1}{4} = \frac{1}{2} - \frac{1}{4} = \frac{1}{4}$.

65. We use the identity $\sin A \sin B = \frac{1}{2}(\cos(A - B) - \cos(A + B))$ to obtain

$$\begin{aligned}\int \sin(mx) \sin(nx) dx &= \frac{1}{2} \int (\cos((m-n)x) - \cos((m+n)x)) dx \\ &= \frac{1}{2} \left(\frac{\sin((m-n)x)}{m-n} - \frac{\sin((m+n)x)}{m+n} \right) + C \\ &= \boxed{\frac{\sin((m-n)x)}{2(m-n)} - \frac{\sin((m+n)x)}{2(m+n)} + C}.\end{aligned}$$

66. We use the identity $\sin A \cos B = \frac{1}{2}(\sin(A + B) + \sin(A - B))$ to obtain

$$\begin{aligned}\int \sin(mx) \cos(nx) dx &= \frac{1}{2} \int (\sin((m+n)x) + \sin((m-n)x)) dx \\ &= \frac{1}{2} \left(-\frac{\cos((m+n)x)}{m+n} - \frac{\cos((m-n)x)}{m-n} \right) + C \\ &= \boxed{-\frac{\cos((m+n)x)}{2(m+n)} - \frac{\cos((m-n)x)}{2(m-n)} + C}.\end{aligned}$$

67. We use the identity $\cos A \cos B = \frac{1}{2}(\cos(A + B) + \cos(A - B))$ to obtain

$$\begin{aligned}\int \cos(mx) \cos(nx) dx &= \frac{1}{2} \int (\cos((m+n)x) + \cos((m-n)x)) dx \\ &= \frac{1}{2} \left(\frac{\sin((m+n)x)}{m+n} + \frac{\sin((m-n)x)}{m-n} \right) + C \\ &= \boxed{\frac{\sin((m+n)x)}{2(m+n)} + \frac{\sin((m-n)x)}{2(m-n)} + C}.\end{aligned}$$

Challenge Problems

68. Let $\sqrt{x} = \sin y$, so $x = \sin^2 y$, and $dx = 2 \sin y \cos y dy$. The lower limit of integration is $y = \sin^{-1} 0 = 0$, and the upper limit of integration is $y = \sin^{-1} \frac{1}{\sqrt{2}} = \frac{\pi}{4}$. We substitute and obtain

$$\begin{aligned}\int_0^{1/2} \frac{\sqrt{x}}{\sqrt{1-x}} dx &= \int_0^{\pi/4} \frac{\sin y}{\sqrt{1-\sin^2 y}} (2 \sin y \cos y) dy \\ &= \int_0^{\pi/4} \frac{\sin y}{\sqrt{\cos^2 y}} (2 \sin y \cos y) dy \\ &= \int_0^{\pi/4} \frac{\sin y}{\cos y} (2 \sin y \cos y) dy \\ &= 2 \int_0^{\pi/4} \sin^2 y dy.\end{aligned}$$

Use the identity $\sin^2 y = \frac{1 - \cos(2y)}{2}$ and obtain

$$\begin{aligned}
 \int_0^{1/2} \frac{\sqrt{x}}{\sqrt{1-x}} dx &= 2 \int_0^{\pi/4} \frac{1 - \cos(2y)}{2} dy \\
 &= \int_0^{\pi/4} (1 - \cos(2y)) dy \\
 &= \left[y - \frac{1}{2} \sin(2y) \right]_0^{\pi/4} \\
 &= \left(\frac{\pi}{4} - \frac{1}{2} \sin\left(2\left(\frac{\pi}{4}\right)\right) \right) - \left(0 - \frac{1}{2} \sin(2(0)) \right) \\
 &= \boxed{\frac{1}{4}\pi - \frac{1}{2}}.
 \end{aligned}$$

69. Let $u = \frac{\pi}{2} - \theta$, then $du = -d\theta$, so $d\theta = -du$. Also, $\theta = \frac{\pi}{2} - u$. The lower limit of integration is $u = \frac{\pi}{2} - 0 = \frac{\pi}{2}$, and the upper limit of integration is $u = \frac{\pi}{2} - \frac{\pi}{2} = 0$. We substitute and obtain

$$\begin{aligned}
 \int_0^{\pi/2} \sin^n \theta d\theta &= \int_{\pi/2}^0 \sin^n \left(\frac{\pi}{2} - u \right) (-du) \\
 &= - \int_{\pi/2}^0 \left[\sin \left(\frac{\pi}{2} - u \right) \right]^n du \\
 &= \int_0^{\pi/2} [\cos u]^n du \\
 &= \int_0^{\pi/2} \cos^n \theta d\theta
 \end{aligned}$$

where we used the identity $\sin\left(\frac{\pi}{2} - x\right) = \cos x$.

70. (a) When writing $(\cos^2 x)^{3/2} = (\cos x)^3$, a mistake is made. When $\frac{\pi}{2} < x \leq \pi$, $(\cos x)^3 < 0$, but $(\cos^2 x)^{3/2} > 0$. The correct equality would be $(\cos^2 x)^{3/2} = |\cos x|^3$.
- (b) Use the identity $\cos^2 x = \frac{1 + \cos(2x)}{2}$ and obtain

$$\begin{aligned}
 \int_0^\pi \cos^4 x dx &= \int_0^\pi (\cos^2 x)^2 dx \\
 &= \int_0^\pi \left(\frac{1 + \cos(2x)}{2} \right)^2 dx \\
 &= \frac{1}{4} \int_0^\pi (1 + 2\cos(2x) + \cos^2(2x)) dx \\
 &= \frac{1}{4} \int_0^\pi dx + \frac{1}{2} \int_0^\pi \cos(2x) dx + \frac{1}{4} \int_0^\pi \cos^2(2x) dx \\
 &= \left[\frac{1}{4}x \right]_0^\pi + \left[\frac{1}{4} \sin(2x) \right]_0^\pi + \frac{1}{4} \int_0^\pi \cos^2(2x) dx \\
 &= \left[\frac{1}{4}\pi - \frac{1}{4}(0) \right] + \left[\frac{1}{4} \sin(2\pi) - \frac{1}{4} \sin(2(0)) \right] + \frac{1}{4} \int_0^\pi \cos^2(2x) dx \\
 &= \frac{\pi}{4} + \frac{1}{4} \int_0^\pi \cos^2(2x) dx.
 \end{aligned}$$

We evaluate

$$\begin{aligned}\int_0^\pi \cos^2(2x) \, dx &= \int_0^\pi \frac{1 + \cos(4x)}{2} \, dx \\&= \frac{1}{2} \int_0^\pi (1 + \cos(4x)) \, dx \\&= \left[\frac{x}{2} + \frac{\sin(4x)}{8} \right]_0^\pi \\&= \frac{\pi}{2} + \frac{\sin(4\pi)}{8} - \left(\frac{0}{2} + \frac{\sin(4(0))}{8} \right) \\&= \frac{\pi}{2}.\end{aligned}$$

We now obtain

$$\int_0^\pi \cos^4 x \, dx = \frac{\pi}{4} + \frac{1}{4} \left(\frac{\pi}{2} \right) = \boxed{\frac{3\pi}{8}}.$$

7.3: Integration Using Trigonometric Substitution

Concepts and Vocabulary

1. True.
2. (d), $x = 4 \tan \theta$
